The object of my visit to Ascot occupied some little time and it was not until ten minutes past nine that we were again under weigh for London. On the return journey our party was reduced to three in number and with a clear night, a clear road, and a

motor on its best behaviour we came along as far as Egham at an exhilarating pace. Here a collie dog gave us considerable trouble, the animal persisting in making the pace for us for over a mile, it not being until Staines bridge was reached that we managed to get rid of it. Passing slowly through the town of Staines full speed ahead was signalled by Mr. Stanton to his gear as we once more got on to the solitary road, and, without having met a vehicle or person for several miles, we reached Bedfont, which, what with the roundabouts, shooting galleries, sweetstuff stands, etc. on the green, presented a lively appearance. We now began to overtake heavy wagons taking vegetables to the London market, and also a few straggling vehicles returning to town from Ascot. Giving the latter as wide a berth as possible, the delay on the home journey not having increased the capacity of the drivers of these conveyances to drive, we successfully ran through Hounslow, Isleworth, and Brentford, and on to Kew, where we arrived at 10.20 p.m., and where Mr. Stanton slowed up just sufficiently

THE MISSES LAWSON ON THE LAWSON MOTOR-WHEEL.

[Argent Archer, Kensington.

to allow me to alight with safety, and with a hasty "good-night" the car sailed away, all that I could see being its two red lights at the rear. Not for a long time have I enjoyed an automobile trip so much, and my visit to Ascot will long remain a pleasant memory as much for the journey by road as for the opportunity I had of inspecting the Royal motor-car.

MR. F. R. SIMMS (vice-chairman), Mr. Worby Beaumont, and Major Holden have been appointed to represent the Automobile Club at the International Congress on Automobilmism in Paris from July 9th to 16th.

AT the last meeting of the Club Committee of the Automobile Club a letter was submitted from Lady Garvagh, suggesting that ladies might become members of the club without being permitted to make use of the club-house. It was agreed that the suggestion should be placed before the next annual general meeting.

THE DE DION STEAM CHAR-A-BANC.

ALTHOUGH in this country we are only acquainted with the motor-cycles and voiturettes propelled by petroleum-spirit motors turned out at the Puteaux works of Messrs. De Dion, Bouton and Company, the firm do not confine their attention to petrol, but are still busily engaged on the construction of heavy steam cars, and this week we are able to publish an illustration of a huge twenty-seated char-à-banc of a type which is now being used for public services in various parts of France. The boiler, which is carried on the front platform, is of the firm's own tubular type. Coke fuel is employed, the consumption being stated to be about four kilogrammes per kilomètre traversed. The engine is of the horizontal compound reversing type and is of 30 h.p. capacity. The water tanks have a capacity sufficient for a run of thirty kilomètres, while coke for a seventy kilomètre trip can be carried. The car is fitted with a mechanical change speed gear, and can, it is stated, ascend gradients of 10 per cent.

THE CROWDEN WATER-COOLING COIL.

WATER-COOLING coils, or *refroidisseurs*, as they are termed in France, have now become an integral part of motor-vehicles, propelled by means of petroleum-spirit motors and the variety of types of this class of device is steadily increasing. The latest addition to the list is the cooler which has just been put on the market by Mr. Charles T. Crowden, of the Motor Works, Leamington. The cooler, as usual, consists of a series of tubes fitted with radiating fins. The feature of the cooler is that the tube ends are connected by a light casting fitted with screwed caps. By this means each pipe of the condenser can be readily cleaned out and the scale removed, so that the radiation can always be kept effective. The framework of the cooler for attaching to the car is very strong and light. The device can be fitted without disturbing any of the pipes or connections, the only alteration necessary being in connection with the hinged front board, in the case of a car of the Panhard type, the condenser being placed in front, where it is considered to be more effective. Mr. Crowden informs us that he has fitted several cars with the new cooler with satisfactory results.

MR. HERBERT DE STERN proposes to offer a cup in connection with a motor-car race to be held during his garden party at Strawberry Hill House on Tuesday, the 10th prox.

CAPTAIN COE, of the *Star*, has offered prizes for the best answer of 150 words to the query, "What is your opinion of a motor-car?" apparently suggested by the number of motor-vehicles seen at Ascot last week.

RECENT additions to the list of members of the Automobile Club include Mr. Isidore Clifford, Mr. Charles F. Dixon, Mr. Wilson Noble, Mr. Oscar Selbach, Mr. H. W. Spiller, Mr. George Henderson, Mr. J. H. Green, the Hon. Leopold Canning, Mr. K. Edgecombe, Mr. T. E. Chambers, Mr. Henry Barcroft, Mr. Walter Bourke, Mr. C. Bright, Mr. W. E. Lake, Mr. Isaac Wheeldon, Mr. H. C. Clarke, and Mr. Charles Rivers.

THE London Auto-Car Company, Limited, of Gray's Inn Road, London, W.C., have just introduced a little article which should meet the wants of many users of De Dion air cooled motors who find the radial fins insufficient for the cooling of the combustion chamber. The new article referred to consists of a water-jacketed combustion chamber, which can be quickly fitted to any 1½ h.p. or 2½ h.p. De Dion motor. In shape it is exactly like the ordinary construction chamber, but with water jacket around it, and with ribs cast on the outside as well for radiation. Any amateur can place it on his tricycle himself, as it fits, without alteration, on to existing motors, the valves and dome being simply taken out and replaced into the new combustion chamber. Two gallons of water, it is stated, will last for an eight hours run on a hot day, while the additional weight is but small.

THE AUTOMOBILE WAGON FOR HEAVY DUTY.*

It can be easily proved that the progress of civilisation made by all nations has been closely interwoven with the progress of transportation. In olden days men were well satisfied to live, grow, and end their days wherever destiny planted them. There they established themselves, contented with the pursuits of life which were within easy reach, looking to Nature for their maintenance, and buying and trading with their immediate neighbours, and within narrow bounds. It would be outside the scope of this paper to discuss whether life was then less comfortable than it is to-day, and whether the few commodities then obtainable were insufficient to make existence enjoyable. At the present day our needs are considerable, varied, and ever increasing. It is no exaggeration to state that many a person's happiness is marred for a good many hours if an express package containing personal goods coming from a great distance should not arrive on the hour.

We all know how an improvement in the facilities for rapid passenger transit shifts the centres of districts where people congregate to manufacture, and the districts where they gather to live. Towns prosper or decay according to transportation facilities, and the value of real estate is seriously affected by them. The manufacturer and the farmer knows what it means to buy and sell where the opportunity is greatest, and how important the item of a quick, safe, and economical transportation of their goods has become at the present day, when the fluctuations in the value of raw material have become an ever increasing factor in the cost of the finished product.

Before the advent of the railway overland transportation was limited to the public highways. Washington maintained that the future prosperity of the country would depend on more horses and national roads, and it can be well said that his prediction has been fulfilled if we only substitute for the word "horse" the words "motive power." When, long after Washington's days, the locomotive appeared, the prevailing idea was that there would be little further use for horses and that all traffic would soon be handled by steam roads. It was different. The fact became apparent that traffic begets traffic, and that the increased opportunity which the railway presented stimulated local enterprise and necessitated the employment of more horses and wagons to ply to and from railway stations. It can be safely stated that the amount of merchandise hauled by horses on our streets and over short distances is as great in the aggregate as that carried by the railways over long distances.

The advent of the bicycle and of the electric tram-car characterised similar periods of apprehension on similar lines, and yet statistics show that the number of horses in use has so far been little affected. However, it bids fair that with the advent of the motor-carriage this increase may now be checked, to gradually give way to a diminution in the number of horses used. Some enthusiasts have already predicted that it will be

only a few years before there will be no horses on the streets. This sanguinism is not justified. However, while the horse will continue to remain man's best friend among the brute creation as a saddle horse, and will probably never be wholly substituted in the propulsion of fancy carriages, there can be little doubt that the motor freight vehicle has come to stay and will eventually supersede the horse as a beast of burden. It will evidently be a question of some time and evolution before it will become a universal institution and of the greatest importance to transportation interests.

The motor wagon presents a problem which should admit of no prejudice. It is a case free from sentiment, and merely influenced by economic considerations. The elements constituting in principle a successful motor-vehicle were known and experimented with by enterprising engineers some eighty years ago. The reasons why those experiments did not lead to results are not far to seek. It was then the time of railway development, and the new competition from the railway did not encourage costly experiments for a competitive line. Furthermore, the machinery used in the motor carriages was in a crude and undeveloped state. The revival of the movement, which may be said to have begun not more than ten years ago, has met with a great deal of indifference and prejudice. It has been

contended that these wagons would frighten the horses, while we can say to-day that most horses soon become accustomed to the peculiarities of their new competitor. Most of this opposition has come from prejudiced quarters; many of the opinions have been volunteered by persons who had never ridden in a motor-carriage, and whose remarks were intended for consumption by the home circle. The advantages of any kind of self-propelled vehicles are patent to any one who stops to give the matter unbiassed thought.

THE VINET VOITURETTE. (For description see next page.)

One has only to think how quickly a motor-wagon with its reduced length can thread its way through crowded thoroughfares, and how it thus saves road space which is at present occupied and made dangerous by the oftentimes erratic horse. It may be contended that the heavier weight supported by the largest types of motor-wagons will damage the roads, but this can be proved to be a fallacy, since even if such damage did occur it would be more than outbalanced by the pounding and tearing action of the horses' hoofs.

One of the necessities for the successful running of motor-vehicles, for some time to come, will be a good road surface, and those responsible for the maintenance of public roads could well afford to encourage the new movement, seeing that by the use of motor-wagons a considerable saving will be effected in the matter of street cleaning, let alone the improvements in the hygienic condition of the roads. The matter of safety has often been doubted, and, while we will consider it later when studying the characteristics of different systems of motor-wagons, it may here be said that statistics have already shown the new vehicle to be far safer from accidents than the horse-drawn vehicles.

At times the horse will stop of its own sweet will, and refuse to budge, but, in case of emergency, using his best efforts he could seldom pull up from full speed inside of less than thirty yards. It necessarily takes time to communicate the driver's will to the horse's brain, and from there to the horse's muscles.

* Abstract of a paper read by Mr. A. Herschmann, before the American Society of Mechanical Engineers.

A motor-wagon, on the other hand, can be quickly stopped, as powerful brakes are within easy reach of the driver, whose intelligence alone is challenged, in case of emergency. In addition, the driver of the motor-wagon will have a clear view of the road ahead without being perched high in the air. It is very difficult to avoid an accident with a horse-driven wagon should the pole chain break, and it is naturally most likely to break when it is most wanted, *i.e.*, when suddenly pulling up. There is another important item which is strongly in favour of the motor-wagon as compared with the use of horses. Horses are dependent on the weather. Flies molest them in summer time, and the driver is often led to believe they are sick or tired, and will naturally slacken up for fear of straining them. Climbing a steep hill he will often get off the wagon to save his horses, and it is evident that all this interferes with economical transportation.

(To be continued.)

THE VINET VOITURETTE.

THIS week we are able to illustrate (*see page 293*) a new two-seated voiturette, which has lately been put on the market by M. G. Vinet, of 25, Rue Brunel, Paris. The frame of the car is of tubular construction, and is so arranged that any form of body may be attached thereto. The motor is a $3\frac{1}{2}$ h.p. water-cooled De Dion, located in the fore part of the frame. Three forward speeds—10, 20, and 35 kilometres per hour—are provided, the power of the engine being transmitted by a single belt to a small counter-shaft behind the rear axle. The change in speed is obtained by means of three pinions on the counter-shaft, any one of which can be brought into gear with corresponding pinions on the rear axle. A special arrangement is provided whereby the belt can be tightened or slackened as desired. Thus in the case of a block in the traffic the motor can be instantly thrown out from the transmission by slackening the belt, this being also done when changing the speeds. The variable speed-gear works in an oil-containing case, and is consequently protected from dust and dirt. Ample brake power is provided, there being a hand brake on the differential gear and similar brakes on the hubs of each of the rear wheels. The frame and body are suspended on easy springs, and it will be noticed that not only is the wheel base a long one, but that the centre of gravity is very low, there being consequently very little liability for the car to overturn. Steering is controlled by an inclined hand wheel. The weight of the car is about 5cwt.

THE quarterly 100-mile and hill-climbing trial organised by the Automobile Club is fixed for Wednesday, the 27th inst.

THE Automobile Club of Austria is organising a motor-car tour from Vienna to Paris, in connection with the Exhibition.

A LARGE ten-seated wagonette, with canopy, was just on the point of being despatched to the Derby Motor-Car Company when we looked in at the dépôt on Holborn Viaduct, E.C., of the Motor Manufacturing Company, Limited, the other day.

MR. F. W. HUDLASS, of the Phoenix Works, Southport, has sent us a copy of an illustrated price-list he has issued. It gives particulars of the Hudlass five-seated car recently illustrated in these columns, also of the Hudlass petrol motor and a variety of accessories.

WE learn that the hill-climbing trials of motor-vehicles announced by the Catford Cycling Club to take place at Westerham Hill at 7 p.m. on Saturday, the 30th inst., will be held under the rules of the Automobile Club, as the rules of the National Cyclists Union do not affect road trials. The rules of the A.C.G.B.I. will permit of the pedalling of motor-tricycles in this competition.

THE Scottish Motor Company, Limited, has been formed with a capital of £10,000 in £10 shares, of which 500 are now being subscribed for. The chairman is Mr. John Harper, jun., of Aberdeen, and Messrs. W. Harper and R. J. Murray are the joint managing directors. A building in Hope Crescent, Edinburgh, is to be rented, and a concrete track will be laid on which purchasers will be taught to drive. The sole agency for the Benz car in Scotland has been acquired.

ACCIDENT.

AN accident, in which one of Mr. A. C. Harmsworth's motor-cars figured, recently took place in Castle Street, Reading. The car was in charge of Mr. Harmsworth's engineer and valet, and was proceeding to the station with a number of trunks. As it was being steered around a carriage a young woman, who was on a bicycle following a cart, going in the opposite direction, wheeled out (on her wrong side of the road) just in front of the car. The driver tried to turn out of her way, but she appeared confused, and steered right against the machine, which knocked her down. One of the wheels passed over her head, and her face was considerably injured, though the mischief was found to be by no means so great as was at first feared, the wheels of the motor-car being fitted with very resilient pneumatic tires.

FURIOUS DRIVING CASE.

AT the Hull Police-court, on Saturday, Thomas Henry Hawley, thirty-five, cycle and motor-car manufacturer, Scarborough, was charged with driving a motor-car at a furious rate on the South Foreshore Road, Hull, the previous day. Defendant denied the charge. P.C. Mansfield deposed to seeing defendant drive the car, in which was a lady, along the thoroughfare in question at full speed. On defendant returning witness spoke to him. There was a great deal of vehicular traffic at the time, and the reckless conduct of the defendant involved great danger. Defendant said that even at a slow rate the revolutions of the engine were extremely rapid, and this probably gave the witnesses a wrong impression as to the actual speed. At twelve miles an hour there would be 1,500 revolutions per minute. The magistrates imposed a fine of £1, including costs, the Chairman remarking that the Bench regarded the case as a very serious one.

DAMAGING A MOTOR-CAR.

AT the Merthyr Police-court, on Monday, David Lewis was summoned for wilfully damaging a motor-car, the property of the Merthyr Motor-car Company. Mr. D. W. Jones appeared in support of the summons, and the defendant was represented by Mr. Beddoe. The defendant is a brakedriver, and it seemed from the evidence that whilst the car was on the stand at Troedyrhiw he got on the driver's seat and set the car going, with the result that it collided with a brewer's dray and was damaged to the extent of £5. The defendant was fined 10s and costs, and ordered to pay the £5 damage, two month's time being given to him to find the money.

AN ACTION FOR WRONGFUL DISMISSAL.

AT the Norfolk and Norwich Assizes last week, the case of Egerton v. Pennington and others was heard. This was an action for the recovery of damages for wrongful dismissal. A special jury was empanelled to try the case. Mr. Kemp, Q.C., and Mr. Low were for plaintiff; defendants were unrepresented. In opening the case, Mr. Kemp said plaintiff was Mr. Herbert Wingfield Egerton, a young man, the son of a Norfolk clergyman living at Weston. The question the jury had to decide was simply what amount of damages was due to his client. He had made a study of motor-cars and cycles, and was approached by defendants, motor-car manufacturers, of London, to come into their employ. He entered into an agreement with them for five years, the salary to be £200 for the first year, rising £30, with a minimum commission of £100 the first year, £150 the second, and rising £30 a year. He entered their employ on February 23rd, 1899, and on July 26th of that year was told by Mr. Pennington that he had better take a short holiday. He came down to his father's home in Norfolk, and, although he wrote them on several occasions he was unable to hear from his employers. He subsequently sued them in the High Court for a month's wages, and succeeded in obtaining a verdict. Defendants were also absent on that occasion. The total amount receivable under the agreement was £2,032. Of this he had received six months' wages and commission.

Plaintiff, in giving evidence, stated that after six months' inaction he obtained employment with a London motor-car syndicate, but it was not very satisfactory, and he relinquished it. He was out of a situation now, but had reasonable prospect of obtaining one.

Summing up, Judge Bigham pointed out to the jury that plaintiff was entitled to recover for what benefit he had been deprived of by his employment having been taken from him. He had been out of a situation for six months, and there was also £16 3s. 4d. due to him as wages. He advised the jury to give but moderate damages, as he thought they would adequately meet the case. The jury retired for private consultation. Returning into Court a few minutes later, they announced that they had decided to award plaintiff £16 3s. 4d., wages due to him, and £300 damages. His lordship remarked that it was a very proper verdict.

A 100-KILOMETRE race between Salon, Arles and Salon is being organised by the Automobile Club de Salon for July 1st. The competition is open for (1) cars weighing over 400 kilograms, (2) motor-cycles, and (3) voiturettes weighing less than 250 kilograms.

THE Motor-Car Journal.

Vol. II.]

LONDON, SATURDAY, JUNE 30, 1900.

[No. 69.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

ON Wednesday morning the discussion on Professor Hele-Shaw's paper on Road Locomotion was resumed at the Institution of Mechanical Engineers. Most of the discussion was, however, of a different character to that we would have expected at such a meeting, and the points of constructional interest that were elucidated were not many. Mr. E. J. Chambers thought that the Institution should take up

the question of motor-cars, and Mr. Bryan Donkin urged more study of the vibration of cars. Mr. Allen Jones deplored the lack of knowledge of the rules of the road shown by some automobilists. Mr. H. Sturmeay asked engineers to study the circulation of the water, as the failure of the pumps was the cause of the greatest number of troubles during the recent Trial. Mr. Hemming, an American representative, spoke strongly in favour of the noiselessness of the American motor, instancing the Stanley (now known as the Locomobile) steam vehicle as a case in point. With regard to smoke, he declared the two factors necessary to secure its absence were the use of the best American oil and American anthracite coal—a statement doing honour to his appreciation of American things, and one that greatly amused his audience.

The Tare Weight:

SUBSEQUENT speakers included Mr. Fowler and Mr. Thornycroft. The former had had six months' experience with a heavy lorry and recognised that it was essential that steam should be employed in such work. There had been

no troubles with horses when the drivers did not call the attention of their animals to the presence of the motor-vehicle. The only animal with which they had had trouble was a bull fastened to a cart, that wanted to charge the lorry and upset the cart in the attempt. He thought the proposed trials at Liverpool were scarcely long enough and vehicles should be run at least six months, as many little things developed in the course of constant running that could not be ascertained in a week's trial. The three-ton tare necessitated the use of a great deal of aluminium, and if the tare could be raised it would be a great advantage. The boilers, too, should be as large as possible. Mr. Thornycroft referred to the restriction of the present tare limit and thought the Institution of Mechanical Engineers might try to secure a raising of the present limit. Mr. Worby Beaumont dealt with the question of roads and the comparative costs of motor, horse, and railway cartage.

End of the Discussion.

He was followed by Mr. Sydney F. Walker, who said that the electrical vehicle would be the vehicle of the future, for it would secure a perfect method of control. At the present time there was an undoubted drawback in the fact that the electrical accumulator would only provide for a run of forty

miles. He believed that to obtain the current without the lead plate might provide a remedy in the future. Mr. Holroyd Smith suggested that some of the details in the paper would provide material for future discussions. Having criticised a few of the points he described a method of securing a perfect radial movement between the hub and the tire, and no other movement—a necessary condition in any spring wheel. In his reply Professor Hele-Shaw promised to make some addenda to his paper, and gave full particulars of the trials projected by the Liverpool Self-Propelled Traffic Association.

A Display of Cars.

DURING the latter stages of the discussion a few motor-vehicles were being assembled in front of the handsome building of the Institution of Mechanical Engineers at Storey's Gate. The first to arrive were three heavy vehicles on the Thornycroft system, two being steam vehicles for Messrs. Harmsworth, and the other the motor dust-cart which the Strand Board of Works has been employing with marked success. Then came a motor-tricycle, and Mr. W. J. Peall on his Daimler was the next to arrive. Mr. C. Cordingley's Iveagh phaeton, Mr. Mark Mayhew's Peugeot, Mr. T. B. Browne's Panhard (with Captain Langrishe as passenger), and Mr. Roger Wallace's car (driven by Mr. Northey), gave the engineers some idea of the lighter vehicles about which something had been said in the course of the discussion. In one thing they were disappointed. Instead of appearing on his famous 1,000-mile Trial car, Mr. Rolls came along on a bicycle with a very large gear wheel. It had been anticipated that more vehicles would have been *en evidence*. The dull morning probably had something to do with the meagre display.

The Automobile Club 1,000-mile Trial.

THE final meeting of the Judges for the recent Automobile Club 1,000-mile Trial took place at the club on Tuesday, 26th inst., when the list of awards was completed, and together with the judges' reports were passed into the hands of the printers. The number of calculations on various points which were considered by the judges, in arriving at the awards, exceeded 1,500 in number. We understand that the awards will probably be made public on the morning of Friday, July 6th.

Motor-Car Trips.

THE Midland Motor Agency, of Acocks Green, Birmingham, has bought up the cars and stock of the Motor Touring Company, Ltd., of Llandudno and Stetchford, and proposes to run the cars to places of interest in the Midlands and also to let them out on hire. The purchase includes the whole of the assets of the projected Motor Excursions, Limited. The manager of the Midland Motor Agency is Mr. A. J. Aldred, who was manager to Captain Cragg in the formation of the Motor Touring Company—the first company, it is said, formed for the purpose of working a passenger service.

A Run from Brighton.

ON Saturday Messrs. Blake and Rush, with four other gentlemen, went to Newhaven to meet a 6 h.p. Panhard wagonette, on which they made a good run to Brighton, the only difficulty arising from the heating of the bearings. The car was stabled with Messrs. Monk and Lonsdale, of Brighton, who are splendidly equipped for dealing with motor-cars, and whose attentions to the vehicle were much appreciated. On Sunday the party of six came up to London on the wagonette in very stormy weather. This, however, did not seriously detract from the pleasure of the trip, as the car is fitted with a canopy and waterproof curtains and has a glass front.

Motor-Cars for Military Purposes.

MAJOR-GENERAL SIR F. MAURICE, K.C.B., has proposed a scheme for the utilisation of cyclists for defensive purposes, which is to receive a full trial on the August Bank Holiday. Not only is he an advocate of the extension of military cycling, but he is also of opinion that motor-cars could be usefully employed and he will be glad of the opportunity to use them experimentally if he can obtain suitable vehicles for the purpose. This is a chance of which motor-car manufacturers should be very ready to avail themselves, and we shall be glad to know that several vehicles of different types have been brought to the notice of Major-General Maurice for experimental purposes.

MESSRS. E. J. PENNINGTON AND C. G. WRIDGWAY TESTING THE LATEST PENNINGTON CAR IN AMERICA.
Coming down hill at about 60 miles per hour!

An Automobile Club for Yorkshire.

A MEETING of gentlemen interested in automobilism was held in Leeds a few days ago, and presided over by Dr. Farrow, of Cleckheaton, to consider the question of the formation of an automobile club for Yorkshire. It was decided to form a club to be called the Yorkshire Automobile Club, that it should be affiliated to the Automobile Club of Great Britain and Ireland, and that the subscription be £1 1s. per year, with associates at half the price. A committee, consisting of Messrs. R. Winn, C. Korte, A.W. Dougall (Leeds), H. Hay (Bradford), J. E. Tuke (Harrogate), Dr. Farrow (Cleckheaton), with A. I. Greenwood as hon. sec., was chosen to draft rules, etc., to be submitted to a further meeting.

Proposed Tax on Automobiles.

WHAT brilliant ideas emanate from the minds of some rural councillors! This is especially the case with regard to motor-vehicles, etc., which are calculated to quicken the progress of the world. Some few months ago the Yeovil Council distinguished itself in an attempt to reduce the speed of motor-vehicles, and now the Ashbourne (Derbyshire) Rural District Council is circularising similar bodies with the view of inaugurating a combined movement to secure the imposition of a tax on cycles, motor-cycles, and motor-cars. The worthy councillors suggest that the proceeds of the tax should be devoted to the repair of the highways. This is, of course, a very desirable use

of the money, but, seeing that the wear and tear of motor-vehicles on roads is considerably less than that caused by horse-drawn vehicles, does it not seem absurd to suggest that the owners of automobiles should be taxed to repair the damage done by horses and the vehicles with which they are associated?

Automobile Racing in America.

IN our issue of May 4th last we gave the results of the first automobile road race organised by the Automobile Club of America. The distance was fifty miles and the route from Springfield to Babylon, N.Y., and back. There were nine starters, of which seven finished. It will be remembered that the race was won by Mr. A. L. Riker, who, driving an electric car, made the journey in 2 hrs. 3 min. 30 sec. On page 305 we are able to publish, by the kindness of our American contemporary, the *Automobile Magazine*, three snapshots, taken during the race. The first shows Mr. C. J. Field driving a De Dion voiturette, with which he secured the sixth place in 2 hr. 48 min. 42 sec. The second illustration shows Mr. A. C. Bostwick and M. Léonce Blanchet. The former gentleman who is now in France, as recorded in our last issue, opened the eyes of French racing *chauffeurs* by securing third place in the Bordeaux-Perigueux race. The third picture of the series depicts Mr. A. L. Riker, the winner, arriving on his electrical car at the finishing point of the race.

The Split in the Belgian Automobile Club.

As was anticipated, the secession of certain members from the Belgian Automobile Club has duly come about, and now Belgium as well as France rejoices in a new society. It is reported that at the initial meeting of the secessionists, among whom, by the bye, General Willaert is a prominent figure, it was decided to style the new organisation the Moto-club of Belgium, but as there is already in existence a society bearing this name, it is evident that the new club must adopt another title. I believe, writes our Paris correspondent, that I am correct in saying that the Moto Club de Belgique has for its president M. Léon Dehaut, and that it has been in existence some eighteen months. After all the name matters but little, and if the members of the new society are really prompted by a desire to see the promotion of the welfare of the industry, and are not motivated by any personal feelings against the leaders of the "A.C.B.," automobilism in Belgium should certainly benefit by the appearance of the new organisation. If, on the other hand, it is simply the result of personal disagreement, then the industry, as well as both the old and new clubs, will be made to suffer.

Tolls.

OUR correspondence columns this week contain something of interest to those who go by motor-car to Marlow and elsewhere. We also give information with regard to the Automobile Club's attitude towards similar charges as are referred to by Dr. Dobson. We are glad that gentleman has written on the subject, and feel confident that if every automobilist who is charged these exorbitant tolls would write to us on the matter the publicity thus obtained would help any agitation that may be raised for their removal. The instances given are not the only ones that could be mentioned, and it is gratifying to know that the Automobile Club is watchful of the interests of motorists in this respect. Every individual owner can help his fellow-motorists by making public the charges at the various toll gates through which he passes.

Spatula.

To spread plaster over another substance or to assist in counterfeit work a spatula is often necessary, but that it should have been adopted by motorists to lay a certain veneer of dignity upon themselves is surprising. Decorum should warrant silence when confrères go ahead. Such a course would certainly be found more dignified than spiteful exclamations—

cheap though they be—and we would urge these who thus employ themselves to make a better use of their time.

Electrical Vehicles.

In his presidential address at the Convention of the Municipal Electrical Association held at Huddersfield, Mr. A. B. Mountain referred to electricity in connection with motor-vehicles. When considering the various types of motor-cars now on the market, he said, it might be imagined that electricity was of little use, because the length of run was limited to about forty miles with one charge, and that the difficulties of charging impeded its application. These difficulties disappeared if they considered the commercial use to be made of the motor-car. As a means of conveyance for tradesmen, cars would not be required to cover more than about twenty miles a day, and if municipalities arranged charging stations in convenient positions such cars should be speedily adopted. If the charging were done at night or in the early morning energy could be supplied at a very low cost. For long distances petroleum at present had an advantage over electricity owing to there being no facilities for charging in out-of-the-way places.

A Strange Affair.

MR. MOFFAT FORD and the South-Eastern and London Chatham and Dover Railways have been engaged in litigation, the former bringing an action for assault. From the report appearing on another page the ordinary reader will see the yard at Victoria Station must have been in something like confusion, and that the antipathy of the cabmen to the motor-vehicle was probably the cause of the difficulty. That being so, it seems strange that the railway company should have allowed the case to go into Court, for although they may have been technically right, it does seem to be straining a point to refuse the assistance of their own police in taking the name of a boy who was obviously in the wrong. Motorists should be very careful when at Victoria.

Motor-Cycle Racing at the Crystal Palace.

THE motor-cycling contest at the Crystal Palace this afternoon should prove of considerable interest. The meeting is under the auspices of the Automobile Club and will commence at three p.m., when the one hour scratch race will be started. For this Messrs. F. Wellington, C. Machin, Moffat Ford, S. F. Edge, C. Jarrott, and E. Buck have entered. In the ten miles handicap all these have entered, together with Mr. J. Cusins. Messrs. F. Wellington, C. Machin, J. Cusins, S. F. Edge, and E. Buck will compete in the five miles scratch race and in the three miles club handicap the entries are Captain Langrishe, Messrs. Campbell Muir, C. Jarrott, and S. F. Edge.

The Officials.

ALL the above competitors have been registered under the rules of the A.C.G.B.I. The officials of the track will be as follows:—Judge, Mr. R. E. Phillips; starter, Mr. T. W. Staplee Firth; observers, Hon. C. S. Rolls, Hon. J. Scott Montagu, M.P.; Sir D. Salomons, Bart.; Mr. Robert Todd; hon. timekeeper, Mr. Harry J. Swindley; competitors' steward, Mr. C. Johnson.

Courtesy on the Road.

DESPITE the crisis in China and the news from South Africa, the London *Standard* has been able to find space for several letters from correspondents complaining of motorists who took no notice of signals to stop when asked to do so. Unfortunately there are drivers of motor-cars who lack consideration for nervous horses and frightened drivers of horse-drawn vehicles, but their number is few. It certainly is the duty of automobilists to show ordinary courtesy and to pay proper respect to the feelings of nervous horses, and we are certain that

the great majority of motorists do not err in that respect. But the fact that there are some who ride, never heeding passing traffic, is to be regretted. Those who write to the papers to magnify the number of such delinquents should remember that they constitute but a small proportion of automobilists.

Motor-Cars and Parliament.

THE fact that Mr. A. J. Balfour has ordered a voiturette, and will soon be classed among automobilists, should be encouraging to those who heard Mr. T. W. Russell inform M.P.'s last week that the Local Government Board was considering the identification of motor-cars. Mr. R. J. Price, one of the Norfolk members, appears to have heard that some motor-cars have been driven about the country at an excessive speed, and has asked whether a provision could not be made compelling every motor-car to carry a distinctive number, of such a size as to render identification easy. Evidently the opposition to the progress of automobilism is not yet inactive, and motorists must be prepared to unite for their mutual protection.

Roads in Ireland.

MANY automobilists who went on the 1,000-mile tour, and many who did not, would like to make a similar progress through Ireland next year. Certainly the experience would be a delightful one if fairly decent stretches of road were selected. We are glad to see from the Wexford papers

THE 1000-MILE TRIAL. THE GEORGES RICHARD CAR AT ST. ALBANS.
(Photo by) (Mr. E. Kennard.)

that Colonel Magrath is endeavouring to arouse the local authorities to some recognition of their duty in improving the roads and so rendering such a tour possible and pleasant. There is no doubt an automobile pilgrimage would prove of great advantage to the hotel-keepers and to those who are anxious to make Ireland popular among tourists, and hence we hope the Colonel's advice to the local authorities to improve their roads will be acted upon. If the Irish people would bring their roads to the standard of English highways they would have a great influx of visitors, pedestrians, and cyclists, as well as motorists. Irish newspapers wishing to see the further prosperity of their country would materially assist its progress by drawing attention to this urgent need.

THE British Consul in Java, in his report for 1899, just issued, states that a firm in mid-Java has lately taken up the import and manufacture of motor-carriages, tricycles, etc. The trade is, he adds, however, still a small one, prices being somewhat prohibitory.

SPEED TRIALS IN BELGIUM.

UPON the Sunday following the Gordon-Bennett International Cup race the Automobile Club of Belgium held a series of speed trials over a distance of one kilometre on the well-known Dieghem road at Brussels, when some remarkable times were achieved. In the category reserved for cars fitted with motors of more than 12 h.p., two of the racers specially built for the International event were competing, and, as would naturally be expected, the greatest interest was manifested in their achievements. Belgian automobilists had been keenly disappointed by the non-starting of these cars in the cup race, for capital performances had been confidently anticipated from them; indeed, some of their more enthusiastic supporters had even expressed belief in an outright win for the Belgian colours. But the uncertainty as to whether the race would or would not be contested on the 14th instant seriously interfered with the arrangements of the Belgian contingent, and when upon the Tuesday afternoon previous to the *course* the international representatives decided to hold the race upon the originally selected date it was seen that Belgium's specially constructed cars would not be received in time to line up at the start. As a matter of fact the vehicles only arrived in Paris a few hours before the start of the race, and during that eventful Thursday they were resting tranquilly at the railway station. No wonder then that a goodly crowd of motor-men assembled last Sunday afternoon to witness these mighty racers go whizzing by upon the Dieghem road. Constructed on the Bolide system, these two cars are provided with 30 h.p. motors, and should their staying powers equal their pace they would certainly have run Charron and his Panhard pretty close in the cup contest. On Sunday last M. Jenatzy's mount made the kilometre, with flying start, in 38½sec., which represents a speed of 94 kilometres, or 59 miles per hour. This is the fastest time ever officially recorded, the previous best being that made by M. Albert Lemaître on his Peugeot during the Nice week of 1899. M. Lemaître's time upon that occasion was 47½sec., but it must be borne in mind that there are now in France several cars quite capable of greatly improving upon this figure. Take for example M. Levegh's performance in the Bordeaux-Perigueux event early this month, when he covered 116 kilometres in 81min., which represents an average of 42sec. for each kilometre throughout the journey. M. Jenatzy has now the proud distinction of holding the world's kilometre record with flying start on two types of cars, for, as is well known, it was he who drove the electric car, "La Jamais Contente," over this distance in 34secs. The second Bolide car was driven on Sunday by M. Lefebvre, and his time was 39½secs., equalling a speed of 94 kilometres (57½ miles) per hour, also a splendid performance. In another category, that reserved for cars of eight to twelve horse-power, a capital run was made by a Gobron and Brillié, a vehicle which has hitherto not been regarded as particularly fast. This car made the kilometre in 58½secs., equivalent to a speed of 62 kilometres (39 miles) per hour. Coming to the steam cars, a record was achieved by M. Miesse's mount, which ran the distance in 48½sec. which represents a speed of 74 kilometres (46¼ miles) per hour. The previous best was that made by a Serpollet car at Nice this spring, viz., 65½sec. The only other noteworthy performance was that achieved by the 6 h.p. voiturette of M. Guders, which covered the kilometre in 68½sec., or at a speed of 53 kilometres (33½ miles) per hour. In all the categories the majority of automobiles were of home manufacture, a striking testimony to the flourishing condition of the industry in Belgium and the quality of the vehicles constructed. The complete official returns were as follows:—

MOTOR-CYCLES.

		Time in seconds.	Speed per hour in kilometres.
1. V. Dratz	3½ h.p.	57½	62
2. De Ridder	2½ h.p.	76	47

VOITURETTES OF MORE THAN 4 H.P.

1. Guders	6 h.p.	68½	53
2. Liedekerke	6 h.p.	92½	39

VOITURETTES OF LESS THAN 4 H.P.

1. De Ridder	3 h.p.	73½	49
2. Madon	3½ h.p.	73½	49
3. Dratz	3½ h.p.	74½	48
4. Liedekerke	3½ h.p.	95½	37
5. Delin	3 h.p.	108½	33
6. Moutens	3½ h.p.	119½	30

CARS OF LESS THAN 8 H.P.

1. Rivière	7 h.p.	73	49
2. Vanderspeck ..	6 h.p.	78½	46
3. Aubrey	6 h.p.	85½	42
4. Grégoire	6 h.p.	89½	40

CARS OF FROM 8 TO 12 H.P.

1. Roland	—	58½	62
2. J. de Crawhez ...	8 h.p.	67½	53
3. Maus	8 h.p.	101	35

CARS OF MORE THAN 12 H.P.

1. Jenatzy	30 h.p.	38½	94
2. Lefebvre	30 h.p.	39½	92
3. Wilford	15 h.p.	56½	64
4. P. de Crawhez ...	12 h.p.	63½	57

STEAM CARS.

1. Miesse	—	48½	74
2. Blacke	—	86½	41

THE Selby Rural District Council have passed a resolution in favour of a tax on motor-cars.

Two motor-cars have been licensed to run along the front from Hastings to Bulverhythe.

MOTOR-CAR excursions in Paris and district are now being organised by a concern known as L'Auto-Touriste, of Levallois-Perret.

MESSRS. LAMPLUGH AND CO., LIMITED, is the name of a company which has just been registered with a capital of £10,000, to carry on the business of cycle and motor saddle and accessory manufacturers, etc.

MR. C. H. OLIVERSON, of Queen's Road, Southport, is this week removing to his new works at Kendal, which are being equipped not only for the repair of motor-cars and cycles, but also for the construction of new motor-vehicles. Mr. Oliverston tells us that he is about to make a start with the building of half-a-dozen cars, part fitted with single-cylinder motors of from 4 to 5 h.p., and part with double-cylinder engines of 8 to 10 h.p. A feature of the cars will be the transmission gear, this including the Oliverston-Killingbeck variable gear, illustrated in our issue of January 26th last.

THE Automobile Club of America carried out a run from New York to Philadelphia on Saturday, the 2nd inst. Eight Locomobile cars, four Wintons, three Rikers, and two Columbia electrics started from the Waldorf-Astoria at 7.30 a.m. Mr. E. Schwartzkopf went in his fore-carriage petrol 'bus, carrying six passengers and all the baggage. The Automobile Company of America entered one petrol brake, which stopped at Staten Island, owing to a broken clutch. The *Horseless Age* states that Mr. George F. Chamberlain, president of the club, was the first to reach Philadelphia, arriving at the Bellevue Hotel in his Winton car at 7.20 p.m. Sixteen minutes later the second Winton arrived, with Mr. Percy Owen driving, and the Locomobiles and others followed. Mr. Schwartzkopf arrived late, after several minor breakdowns. Two of the Riker carriages arrived late at night, the batteries having been recharged *en route*. The third, which was Mr. Riker's racing machine, sustained a short circuit between Trenton and Princeton, and the two Columbias disappeared somewhere and were not heard of. The run was not supposed to be a race, but it quickly degenerated into a scramble for Philadelphia. Mr. Chamberlain and several others stopped at Princeton at noon and waited till nearly four o'clock for the stragglers. Several heavy showers delayed the run between Princeton and Philadelphia, and all reported the road between Moorstown and Philadelphia to be the worst they ever rode on.

AUTOMOBILISM IN CANADA.

THE progress of the automobile is universal. In pleasure-loving France, in business-like Germany, in go-ahead America and in more conservative England its day is approaching, while our British colonies are watching developments with interest. There is hardly a country where the motor-vehicle has not been; and there is certainly not a land where it could not be usefully employed. Under the diverse conditions that obtain in different climes engineers are at work improving and perfecting older forms of vehicles, and just as the first half of the nineteenth century witnessed great changes in methods of locomotion so the early years of the coming era are likely to see important developments with regard to the highways.

I recently had the advantage of a chat with Mr. W. J. Still, of Toronto, who has done much to further automobilism in the Dominion of Canada. He is of English birth, but has been so long in Canada that he has become as like unto the Canadians themselves—in feeling and sympathies—that he can regard himself as a Colonial. And what matters? Our Empire is so wide and so united that whether born in Surrey or living in Toronto he is a Britisher. Speaking generally on the matter we talked of the influence of national or racial traits on the prospects of automobilism. The Canadian seems to be a compound of Scotch caution and American pushfulness. He is inclined to consider new things and discuss their merits; but he must be fully convinced on the latter point ere he will purchase. Consequently any vehicle likely to secure his practical approbation must be a really commercial success. The Canadian is very thrifty, and horses are very cheap in the Dominion. That is a fact that must delay the progress of the automobile somewhat; still its use in Canada is growing despite the cheapness of horses and the badness of the roads.

"The fact that small independent charging stations are very much more common in Canada than in England," said Mr. Still, "has, of course, done much to help electric automobiles in the Dominion; but the presence of charging stations is not all that is required. The first questions generally are: How will the vehicle go up gradients, can it get out of mud holes, what will it cost, and how far will it go? Those questions answered the results are compared with the work of a horse, costing probably £4, and even then, when the work done is fairly heavy, the comparison frequently leads to the adoption of the motor-car."

Those who saw Mr. Still at the Motor Car Exhibition driving one of his electric phaetons and seated considerably off the ground, were inclined to regard such a high seat as inconvenient as well as unsightly. That may have been the case in this country, but in Canada it is otherwise.

"You must not forget the different conditions which obtain in Canada to those you know in the old country," said Mr. Still, when I sought his confidence on this point. "How should I have got along through twenty inches of snow seated on a vehicle with the axle at the height familiar in England or France? But that is not all. The marked peculiarity, I might almost say the characteristic feature, of Canadian roads is their ruts. In Toronto many of the roads

are composed of round cedar blocks with the intervening spaces filled in with sand, and in the country round about they are formed of what we call macadam. You would call it dirt. In the city itself the holes between the blocks are often eight to ten inches deep. Fancy a man on a De Dion voiturette or a quadricycle enjoying a ride over such roads. Certainly no Canadian would stand it."

Another point that has struck British people as rather strange in the Canadian electric vehicles that Mr. Still has introduced to this country is the sombre character of their appearance.

"The Canadian," I was told in response to my question, "is not generally a man who likes a car or carriage—whether horse drawn or motor propelled—upholstered and finished in bright colours. The American frequently goes in for bright yellow, while the Canadian favours dark blue, black, or dark green. Certainly in motor-cars he will have nothing that departs from what he has been used to in broughams and victorias."

Naturally, Mr. Still is inclined to regard the electric vehicle as the vehicle of the future—especially in countries where electrical developments have been most prominent in other directions.

"Automobilism is advancing," he said, "in both the United States and Canada. Going up the Broadway, New York, some time ago I counted seven horseless vehicles—cabs and delivery vans—and all excepting one were electric."

"What was the exception?" I asked.

"A Stanley steamer. It was a very cold day and the presence of the exhaust steam was clearly apparent. In fact, on the coldest days in our Canadian winters it would not be possible to run steam vehicles owing to the steam condensing on the exhaust pipes."

"Then you are prepared to range yourself with those who unhesitatingly declare for the electric vehicle under almost all conditions?"

"Yes, an electric commercial vehicle is quite possible, and even with the competition of steam and petrol such is likely to make headway. I have

seen nearly all the vehicles in use in this country, and few come up to my idea of what is a commercial vehicle. To be entitled to such a description it should be made so that any ordinarily intelligent driver can handle and keep it in repair and make all the necessary adjustments. Where is the steam or petrol vehicle that comes up to that test?"

It was not for me to answer. So slanting towards the *tu quoque* kind of argument, I asked Mr. Still if the electric vehicles of the company of which he is the consulting engineer—the Still Motor Company, Ltd.—were of such easy management.

"Certainly," he unhesitatingly affirmed. "I can point to a vehicle running in London which is being driven by a storekeeper who had not had any previous experience in handling such vehicles. After half an hour's tuition he was able to go alone. Then, after I had given him ten minutes' instruction in running, he took the car along the Embankment, up Whitehall, across Trafalgar Square, and along St. Martin's Lane without difficulty. He was quick at the work, but any man with fair intelligence could have done the same, and he has been running, cleaning, oiling, and keeping it in repair for three months."

Such an instance naturally gives Mr. Still confidence in the future of the electrical automobile.

"WHYBROW."

MR. W. J. STILL TRAVELLING ON HIS ELECTRICAL PHAETON THROUGH 20 INCHES OF SNOW IN TORONTO.

MOTOR-CARS ON THE CONTINENT.

Public Services in Italy.

ARRANGEMENTS are in hand for the establishment of a public service of motor-vehicles between the railway stations at Mortara and Vigevano and Parona, Cilavegna and Gravelona. It is also stated that a service of electric vehicles is shortly to be started between Spinea, Mirano, Noale, Scorze and Mestre (province of Venice).

The French Moto Club.

FOR the present the Moto Club de France continues to grow apace, and already the names of upwards of four hundred members are enrolled upon its books. The committee pursues its work of elaborating the society's governing rules and regulations with unabated energy, and yet finds time to attend to some of the minor details. A badge has been selected and will be sold to members at a very moderate figure, and an automobile excursion to Tyre-Château, near to Gisors, has been planned for Sunday, July 8th. A capital attendance is expected at this, the first outing of the new club, for already some twenty owners of cars have signified their intention to participate.

The Vincennes Motor-Cycle Competitions.

It was on the 18th instant that the competition for motor-cycles, organised in connection with the Paris Exhibition, commenced at Vincennes, and every day, excepting Thursday, until the 23rd inst., the machines were required to cover nearly 160 kilomètres. The scene of this long and trying competition was the automobile track which encircles the Lake Daumesnil, and the day's work consisted of 70 kilomètres in the morning and 90 in the afternoon. The question of speed did not enter into the judges' consideration at all, the awards being made to those competing cars which, by their regularity of action and their low consumption of fuel, proved themselves to be vehicles entirely suitable for use by the ordinary public, who desire a reliable and economical machine. Twelve machines presented themselves at the start of the contest, and a thirteenth commenced the task upon the following day. These were:—

No.		Motor of	Kilos.
1	Tricycle ...	74 x 76mm.	120
2	Tricycle ...	71 x 80 „	130
3	Quadricycle ...	75 x 80 „	180
4	Tricycle ...	74 x 75 „	130
5	Tricycle ...	80 x 80 „	124
6	Quadricycle ...	90 x 90 „	203
7	Quadricycle ...	90 x 90 „	218
8	Tricycle ...	76 x 90 „	136
9	Motor-bicycle ...	55 x 66 „	42
10	Motor-bicycle ...	55 x 66 „	42
11	Motor-bicycle ...	62 x 72 „	40
12	Motor-bicycle ...	64 x 70 „	—

Of these seven successfully carried out their trials, and on Monday last the official awards were made known. These were:

FIRST PRIZES (GOLD MEDALS).—No. 11. Bicycle-motor, 62 x 72; weight, 40 kilogs.; consumption, 23 litres 870; average speed per hour, 40 kilomètres 300 mètres. No. 1. Tricycle-motor, 74 x 76; weight, 120 kilogs.; consumption, 20 litres 579; average speed per hour, 38 kil. 400. No. 2. Tricycle-motor, 71 x 80; weight, 130 kilogs.; consumption, 20 litres 890; average speed per hour, 39 kil. 600. No. 3. Quadricycle-motor, 75 x 80; weight, 180 kilogs.; consumption, 29 litres 700; average speed per hour, 33 kil. 600.

SECOND PRIZE.—No. 4. Tricycle-motor, 74 x 75; weight, 130 kilogs.; consumption, 24 litres 230; average speed per hour, 39 kil. 500.

THIRD PRIZES.—No. 8. Tricycle-Motor, 76 x 90; weight, 136 kilogs.; consumption, 37 litres 360; average speed per hour, 43 kil. 200. No. 7. Quadricycle-motor, 90 x 90; weight, 218 kilogs.; consumption, 31 litres 770; average speed per hour, 41 kil. 600.

The motor bicycle which secured a gold medal is that known as the Werner; the other first-prize winners are of Rochet construction. Créanche built the second-prize winner, and the silver medals went to the "Energie" and the "Luc" motor-cycles.

The Artistes' Fete.

NEXT Friday, at Longchamps, there will be a fête which annually attracts a mighty crowd, and that is the sportive fête of the theatrical world of Paris. Commencing at two o'clock, the festivities will not cease until six, and throughout the long programme automobiles will play a prominent part. First of all there will be a race for artistes; then, an automobile gymkhana. This will be followed by a procession of florally decorated automobiles of the theatres of Paris, and then an automobile battle of flowers will take place. Later in the afternoon a country fête will be indulged in; and the list of pleasures will conclude with a concert at the Châtelets du Cycle. This is invariably one of the most delightful fêtes of the year, and it appeals doubly to motor-men, for it affords them an opportunity of seeing the prettiest women and the handsomest motor-cars in Paris at the same time. What more can one desire?

The Béconnais Souvenir.

It will be remembered that after the Nice and the succeeding race meetings in the south of France, at which Béconnais raced so brilliantly and with such barren results, some of his admirers opened a subscription list through the medium of the *Vélo* for the purpose of presenting the "roi des motocyclistes" with a souvenir of his performances. This list was closed some few days ago, and after consulting Béconnais' wishes the presentation took the form of a handsome gold watch-chain. *A propos* of Béconnais, it may interest English readers to learn a little of the history of this intrepid rider. Born at Angers in the year 1867, he commenced what proved to be a long and successful career as a racing cyclist in the autumn of 1883, being then sixteen years of age. His maiden race was one of 52 kilomètres from his native town to Janzé, and he was classed but seventh, the winner being another Angevin, now also a famous *chauffeur*, viz., Charron. During the following two years Béconnais continued to race, but with only trifling success, and it was not until 1886 that he came well to the front as a cyclist. In that year he first made his mark by running second to Terront in a four hours' race at Angers, and later on he occupied a similar position in a big event at Agen, the actual winner of the latter *course* being Paul Rousseau, now a director of the *Vélo*. A year later at Angers he ran Charron, Laulan, and Terront very close in an international event, and a few days after this race he succeeded in setting up a record for four hours in the annual *course* at Angers. His distance was 105 kilomètres, and among the vanquished men were Terront, Laulan, and Médinger. In 1888 he did excellently, perhaps his most notable performance being his record of 1h. 36min. 24sec. for the 50 kilomètre tricycle race. During the following season he scored many victories and in 1890 he finished first in thirty and second in twenty-seven events. It was during the latter year that he gained the 100 kilomètre championship of France, beating both Terront and Dervil. During the following eight years—that is to say, down to the autumn of 1898—Béconnais continued to win some thirty races each season, and when in the spring of last year he decided to enter the ranks of the motor-cyclists, the whole French sporting world regarded the experiment with interest. And from his *debut* as a *chauffeur* Béconnais has been wonderfully successful, especially so over comparatively short distances, as witnessed by his marvellous performances over from one to one hundred kilomètres. Certainly at the present moment no one travels so fast as he does, and it was worth going a long way to see the hardly suppressed mirth of one and all in the crowded court at Saint Germain, when Béconnais, in response to the judge's question, blandly stated that on the day of Paris-Roubaix, when occurred the accident at the Croix de Noaille, his speed did not exceed *twelve kilometres per hour*. That little incident will live in the memory of all who were unfortunate enough to be in

court that morning. Béconnais racing at twelve kilomètres per hour! *Quelle vitesse!*

The Electric Race.

AN after effect of the speed at which the competitors in the International Cup race passed through Versailles has been the refusal of M. Poirson, the Préfet of the Seine-et-Oise, to allow the course for electric cars, which was set down for decision last week, to be run over his territory. This interdiction was very unfortunate, for all followers of electric traction were keenly anticipating the race, and the idea of its being prohibited was never for a moment considered, as the speeds attempted by touring electromobiles is never excessive. However, there it is, and unless M. Poirson can later on be persuaded to remove his embargo, manufacturers of electric cars will have no opportunity of displaying the powers of their cars. For the race in question some dozen vehicles had been entered.

Motor Boats.

ON Saturday and Sunday last the international competitions for motor boats, promoted by the Hélice Club, were carried out on the Seine at Argenteuil, and although the management was far from being ideal, the regatta cannot have other than a beneficial effect upon this somewhat neglected branch of the motor industry. Those launch owners who have never employed anything but steam engines upon their craft can have no idea of the conveniences of the petrol motor. The facility of starting without that long and weary wait for a head of steam, the cleanliness, and the certainty of action, all go to make the motor boat an ideal craft. For the entire success of the Hélice Club's regatta it is a pity that the organisation was not more perfect, and that the promoters had not given a little more publicity to their *fête*. Many people who take a keen interest in river locomotion were quite unaware of any such competitions taking place until the regatta was over, and the attendance on the opening day was but very sparse. On the Sunday the presence of a big holiday crowd certainly brightened up matters somewhat, while the semi-official visit rendered by the Rallye-Auto Club brought an influx of many well-known automobilists upon the scene. Several celebrities in the motor world were actually aboard the competing craft, and I may quote the names of Commander Krebs, who was on the Phoenix, M. Garcin on the Riquiqui, and M. Teste, who was in charge of the Aiglon's engines.

Saturday's official results were as follows:—First series, for boats of less than 6m.50 in length: 1, L'Aiglon, petrol; 2, Souris Blanche, petrol; 3, Surprise, petrol, 3½ h.p.; 4, Mandarin, petrol, 2¼ h.p.; 5, Sirène, petrol, 4 h.p.; 6, Nenett, petrol, 3 h.p.; 7, Le Brution, petrol, 2¼ h.p. The winner covered the 50 kilomètres in 2h. 40min., giving an average speed of 18 kilomètres per hour. Second series, for boats of 6m.50 to 8m. in length. 1, Olifant, steam, 6 h.p.; 2, Rainette, petrol, 2½ h.p.; 3, Isabelle, steam, 3 h.p.; 4, Centaure, petrol; 5, Petit Poucet, steam, 4 h.p.; 6, L'Abeille, petrol, 3 h.p. In this class the first boat took 3h. 21min. to make the voyage of 50 kilomètres, which represents an average speed of 15 kilomètres per hour. Third series, for boats of 8m. to 10m. in length: 1, Lisette, steam, 3 h.p.; 2, Suzette, steam, 7 h.p.; 3, Ellen, petrol, 4 h.p.; 4, Iris, steam; 5, Sport Nautique, petrol, 5 h.p. The Lisette made the 65 kilomètres in 4h. 40min., or at an average speed of 14 kilomètres per hour. Fourth series, for boats of 10m. to 15m. in length: 1, Phoenix, petrol, 18 h.p.; 2, Suzanne, steam, 15 h.p.; 3, Favourite, steam, 12 h.p. The Panhard boat took 3h. 49m. to cover 78 kilomètres, thus making the best average of all classes, viz., 20 kilomètres per hour.

The official returns on the Sunday were:—First series, for boats of less than 6m.50 in length, distance 13 kilomètres: 1, L'Aiglon, petrol; 2, Souris Blanche, petrol; 3, La Surprise, petrol, 3 h.p.; 4, Surprise, petrol, 3½ h.p.; 5, Sirène, petrol, 4 h.p.; 6, Mandarin, petrol, 2¼ h.p.; 7, Le Brution, petrol, 2¼ h.p. Second series, for boats of 6m.50 to 8m. in length, distance 13 kilomètres: 1, Centaure, petrol;

2, Rainette, petrol, 2½ h.p.; 3, Marie, petrol. Third series, for boats of 8 to 10 m. in length, distance, 20 kilomètres: 1, Riquiqui, electric, 8 h.p.; 2, Ellen, petrol, 4 h.p.; 3, Suzette, steam, 7 h.p.; 4, Iris, steam; 5, Pygmée, petrol, 5 h.p. Fourth series, for boats of 10 to 15 m. in length, distance 26 kilomètres: 1, Phoenix, petrol, 18 h.p.; 2, Suzanne, steam, 15 h.p.; 3, Favorite, steam, 12 h.p. The failure of the steam launches was even more marked on the second than on the first day, indeed, the petrol craft had matters all their own way, except in the third series, when M. Garcin's electric boat scored an easy victory. Prizes to the value of £1,000 were distributed among the successful competitors.

A New French Voiturette.

M. P. DUPRESSOIR, of Maubeuge (Nord), France, is the builder of the little two-seated voiturette illustrated herewith. The motor is located at the rear of the car, and is geared direct through the medium of a special three-speed gear to the gear axle. The choice of motor is left entirely to the purchaser, either a 2¼ h.p. De Dion or Aster air-cooled motor being fitted, or, if desired, a 3 h.p. De Dion or Aster water-cooled engine. The variable-speed gear is adapted to give 10, 20, or 32 kilomètres per hour, with the motor running at 1,800 revolutions per minute. Steering is controlled by an inclined hand-

wheel, on the standard of which all the control handles—variable speed gear, mixture, ignition, etc.—are mounted. Between the motor and the variable-speed gear a friction clutch is interposed, so that the motor can be instantly thrown out of gear. The clutch is controlled by a foot pedal, the continued depression of which brings into operation a band brake on the differential drum. A second pedal controls band brakes on the hubs of each of the rear wheels. The car is spring suspended at the front, while the wheels are of the cycle type with pneumatic tires. The motor is arranged to be started by the small hand wheel and chain gearing seen at the side, a free wheel device being introduced on the sprocket on the motor shaft. A speed of 32 kilomètres can, it is stated, be readily attained by the car with the engine running at 1,800 revolutions per minute.

THE American Carriage, Car and Motor Manufacturing Company, Charlestown, W. Va., has been incorporated to make and deal in vehicles of all kinds. The capital is £1,000,000!

A BOURNEMOUTH Omnibus Company having recently commenced running on Sundays, the Town Council have unanimously resolved that at the expiration of all omnibus, motor-car, and excursion coach licences, no further licences be issued except on condition that the vehicles should not ply for hire on Sundays.

ARRANGED by the New York *World* some tests in lassoing cows from the seat of an automobile have taken place in Brooklyn. Two "Locomobile runabouts" were selected as suitable vehicles, and the cowboys, who operated from their seats, soon settled down to their work, and after the trial had been successfully carried through one of them said:—"There's one good thing about those carriages—they never buck."

THE BLAKE FOUR-SEATED PETROL CAR.

TOWARDS the close of the exhibition at the Agricultural Hall, Mr. F. C. Blake, of the Ravenscourt Works, Dalling Road, Hammersmith, brought in a new four-seated car built in accordance with his own ideas, and of which we are now able to publish an illustration. The motor is a horizontal four-cylinder one of the petroleum-spirit type, the cylinders being arranged in pairs opposite to one another, the pistons being connected up to a common crank shaft; it is of 7 b.h.p., with water-jackets, and is located in the centre of the rear portion of the frame; its normal speed is 800 revolutions per minute. The ignition is electrical by means of small accumulators, a feature being the employment of only one induction coil, with a special distributor, for the four cylinders. Two speeds, about five and fourteen miles per hour, are provided. The motor-shaft carries a drum, which is connected by a single belt to a first counter-shaft, carrying one loose and two fast pulleys. Connected to each of the fast pulleys is a pinion which gears with corresponding pulleys on a second counter-shaft. The first counter-shaft is carried in swinging arms, the belt being

continually kept taut by means of a spring. From the second counter-shaft to the rear road-wheel axle, which is a "live" one, the power is transmitted by a single chain. The frame is of channel steel, the body being supported thereon through the medium of rubber blocks. The wheels are of the suspension type with solid rubber tires. Steering is effected by means of an inclined hand wheel controlling the front wheels. The petrol tank, which has a capacity of eight gallons, is arranged in the front of the car. The engine is started by means of a detachable handle, while all the working parts of the motor are readily accessible. The water tank is of large capacity, while a radiating coil is also provided. The front mud-guards are fastened to the front axles and move with the wheels, so keeping mud from being splashed over underframe and machinery. A foot pedal controls a hand brake on the counter-shaft, while Price's tire brakes, acting on the rear wheels and controlled by a hand wheel at the side, are fitted. The car appears to run very quietly and with a minimum of vibration. Its weight complete is 10 cwt.

LA SOCIÉTÉ DES AUTOMOBILES PEUGEOT, of Audincourt (Doubs), France, has just increased its capital to £200,000.

A NUMBER of electric vehicles have been shipped from New York to Mexico to the order of the Mexican Electric Vehicle Company.

SOME experiments with motor-cars are about, it is stated, to be carried out by the fire brigade authorities at Frankfort-am-Main, Germany.

STEAM v. ANIMAL POWER FOR HEAVY TRACTION.

THE following statement by Mr. A. G. Lyster, the Engineer-in-Chief, Mersey Docks and Harbour Board, on the working of a Leyland motor-wagon, forms an appendix to the paper recently read by Professor Hele-Shaw before the Institution of Mechanical Engineers:—

This machine, which is a motor-wagon designed to carry a paying load of four tons, has its engine worked by steam generated by liquid fuel. The service is of a very special character, consisting as it does in conveying materials from a central dock-yard, where they are manufactured, to the various parts of the estate where they are required for the works, comprising only comparatively short journeys, and returning with such loads as may be picked up for the yard or intermediate positions. The wagon is by no means, therefore, either constantly fully loaded or employed; it has to wait for longer or shorter periods, according to circumstances, at its several stages or points for discharging or loading, or elsewhere; and altogether the conditions are extremely unfavourable for affording data which would be of benefit to firms whose work is of a more regular and uniform character.

The cost per ton-mile varies very largely according to the nature of the work, being as low as 3·4d. per ton-mile for the work done on a certain day, and at times very much higher, the average over the whole of the time worked giving a little over 9d. per-ton mile.

During the period to which this applies, viz., from the beginning of January to the middle of March, 1900, and providing a total of fifty-two working days, the actual working time was only 44 per cent. of the total.

The work for which the motor-wagon was obtained had previously been done by horses and carts, and no exact data are available for comparison with the new vehicle. In general terms, however, the cost for the work done has been much less than it would have been by horses, and, as regards despatch and convenience, which are often of greater importance in urgent work than direct cost of transport, the comparison is immensely in favour of the motor-vehicle.

It has been very efficient for the purpose for which it was obtained, and its working has been entirely satisfactory. No difficulty whatever has been experienced in manœuvring, but on one or two occasions, after a heavy snowfall, some difficulty was found in starting. This, however, was soon overcome.

EARL RUSSELL was out with a party of friends on his Panhard car on the Ripley road last Sunday.

THE Construction Liégeoise d'Automobiles, Liège, Belgium, send us a pamphlet describing the Duryea motor-car, for which they hold the Belgian patents. The characteristic American features of these carriages and their merits as compared with Continental practice are well set forth, especial mention being made of the low vibration, the details of transmission, and the interchangeability of parts.

THE entries for the motor hill-climbing to be held at Tilburstowe Hill, Godstone, Surrey, on Saturday next, under the auspices of the English Motor Club, will be divided into the following sections, separate awards being given in each:— (A) Tricycles and quadricycles, list price of which shall not exceed £140; (B) Voiturettes, list price of which shall not exceed £150; (C) Voiturettes, list price of which shall not exceed £250; (D) Cars, list price of which shall be between £250 and £500; (E) Any car costing more than £500. A special medal will be given to the motor covering the course in the actual fastest time. The result in each section will be determined not merely by taking the fastest time, but by taking the best time in relation to the selling price of the car and the number of passengers carried. It will thus be possible for a motor owner to win in his section by the careful adoption of the necessary number of people. The entry list will be closed on Monday next.

FROM COVENTRY TO NORWICH BY MOTOR-CAR.

THE following account of a run to Norwich from the Motor Manufacturing Company's Works at Coventry, on a van which the latter company supplied to their order, has been sent us by Messrs. Garland and Sons, of Norwich.

"We were well on the way out of Coventry by 10 a.m., and took the long rise up past Coombe Abbey on the third speed, and managed all the hills to Lutterworth in the same easy fashion, passing through the latter place at 11.15. Nothing of any particular difficulty encountered us until our arrival at Market Harborough at 1 o'clock, just in time for lunch at the "Three Swans." We were informed at the dining table by a gentleman who lived in the neighbourhood that he should be much surprised if we mounted the hills that now lay along our route, but we started off full of confidence in our motor, and left the town, which is a great hunting centre, at 2 p.m.

It was not long before we encountered some hills that fairly staggered us to look at; we rushed well at them and anxiously crept towards their summits—several of them were one in nine at least—and, of course, we had to resort to the first speed, upon which our valiant motor overcame them in capital style, and, nothing daunted, were soon away at top speed and ready for any more of the same description. At 4 p.m. we arrived at Weedon, and stopped a few minutes to send off telegrams and to look over the lubrication, and from this little village onwards the hills, though they would be considered stiff in Norfolk, seemed almost contemptible to us after our past experience. Oundle was reached at 5 o'clock, and here we cooled our good steed and refreshed ourselves at the Falcon Inn. This is a very fine old hostelry, and boasts a grand oak staircase from Fotheringay Castle, the ruins of which are hard by. At 5.50 p.m. we were on our way again, and soon came into altogether smooth waters as we began to near Peterboro'. We reached the latter place at 7 p.m., and started away amid considerable excitement among the inhabitants at 7.10, going at a good speed. We ran into Wisbech at 8.35 p.m., a distance of 19½ miles, having stopped once only—three minutes at a railway crossing. It is a good flat road, and the pace and clear beat of the engines was acknowledged by all on board to be "grand." Here we met friends, and decided to put up for the night, well satisfied with the way the motor had behaved.

We proceeded on our way the next morning at 9 a.m., reaching Lynn about 10 a.m.; just stopping to make a call at the post office, we sped on to Swaffham in first-rate style. Here we had to replenish our stock of petrol, having nearly run out, and, taking on board two gallons of Pratt's motor spirit, we were soon off again, and, *via* East Dereham, made no stop for the remaining thirty miles, until we reached our destination about 2 p.m. We were all highly pleased with the way the motor conducted itself on the trip, and thoroughly enjoyed our journey."

In answer to T.O.C., the makers of the Delaunè tricycles fitted with "Romain" motors are Messrs. Delaunè and Company, 89, Rue d'Illiers, Orleans, France.

THE "PIPE" MOTOR-WAGONETTE.

REFERENCE has already been made in these columns to the motor-vehicles of the Compagnie Belge de Construction d'Automobiles, a concern which has recently established large works in the Place du Châtelain (Quartier Louise), Brussels. We are now able to give an illustration of one type of car turned out by this company—a four-seated wagonette. The motor, which is known as the "Pipe," is a vertical one, comprising two cylinders; it is capable of developing up to 6 h.p., and is fitted with a governor in the usual way. The ignition is by means of incandescent tubes, while the water circulation is maintained by a small centrifugal pump, the water in its circulation passing through a radiating coil. The engine is located under the bonnet in the fore part of a channel-steel frame. Four speeds and reverse motion are available, the method of transmission of the power to the rear road wheels being very similar to that adopted in the Daimler cars—viz., through a clutch to a longitudinal variable gear shaft, connected by spur-wheels to a countershaft above, the power from the latter being conveyed by a bevel gear to a cross shaft and thence to the rear road wheels

by the usual sprocket wheels and chains. The frame is spring-suspended on the axles; the road wheels are of the artillery type shod with pneumatic tires. Steering is controlled by a hand wheel, in proximity to the standard of which are mounted the various control handles. One foot pedal actuates the clutch, while another operates a band brake on the cross shaft. In addition there are band brakes on drums attached to each of the rear wheels, actuated by a hand lever. The motor and transmission gear are mounted on a standard frame, to which any desired type of body can be attached.

THE "PIPE" MOTOR-WAGONETTE.

THE Lowestoft Motor-Car Company, Ltd., Lowestoft, is being voluntarily wound up.

MR. ELMER A. SPERRY, of Cleveland, read a paper on "Automobiles as a Source of Revenue to Central Stations" before a recent meeting of the National Electric Light Association in Chicago.

THE Secretary of the Automobile Club asks us to state that the average speed of the Wolseley voiturette, No. 40, on the run from Sheffield to Lincoln in the 1,000-mile Trial was twelve miles per hour, not ten and a half miles, as given in the table recently published.

LA Société des Automobiles Créanche, of Rue Brunel, Paris, has sent us a copy of its 1900 catalogue, which gives particulars of the Créanche electrical and petrol cars, and also the motor-tricycles and quadricycles made by the company, the latter being fitted with De Dion motors.

MESSRS. H. PERCIVAL AND COMPANY, of Saracen's House, Snow Hill, London, E.C., have been appointed agents in the United Kingdom for Mr. W. H. Dorey, of Paris, wholesale factors of fittings and parts for motor-cars and cycles of all kinds, also of motors, complete cars, and cycles, etc. Those interested in the motor industry will find the new illustrated list the firm have just issued very useful.

CORRESPONDENCE.

AN IMPROVED MOTOR-QUADRICYCLE WANTED.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Your journal appears to have a large circulation among both motorists and makers, and I therefore beg to put forward a suggestion for their consideration.

The 2½-h.p. air-cooled motor-tricycle has two serious drawbacks—the heating of the engine, and the excessive vibration, the latter due to the three separate wheel tracks. Let us have a two-track machine, a quadricycle, fitted with 3-h.p. or 3½-h.p. water-cooled motor. Those objections would disappear; the machine would possess plenty of power, be reliable in action, and be able to run a long journey without a stop, as a large supply of petrol could be carried. There should be a comfortable large air-cushion saddle, with low back and arm-rest, pedals, and 36-inch gearing for starting, and a wind-shielded platform for foot-rest during journey.

Such a machine would beat anything for tours (one man and luggage aboard), and there would be such a large demand for it that it could be turned out at £80, with satisfactory profit.

Yours truly,

London, W., June 23, 1900.

H. J. C.

ROAD IMPROVEMENT.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—There appeared not long ago in the *Spectator* an article on the subject of motor-cars, the writer of which summed up by saying: "The motor-car has given us back our roads." In dealing with the question he considered motor-cars chiefly as a means of pleasure traffic; which, I think, will not be so great in, say, ten years time, as the light goods traffic, much of which at present is carried by railway, will in all probability be carried by road as being both cheaper and quicker. This brings us to the question of whether our roads are capable of safely carrying a traffic of this sort. I am speaking of country roads. No doubt our main roads are wide enough for a considerable increase in the number of vehicles travelling; but there are many sharp corners, steep gradients, and narrow stretches even on our most important highways which would be a constant source of danger to rapid road traffic in any quantity. A maximum steepness of gradient and minimum radius of curve, as well as minimum width, should hold good for all main roads, and the classification of roads should take into consideration gradient as well as surface. It is a large subject, but I write this hoping that it may call the attention of the Automobile Club and automobilists in general to the very important question of preparing our roads for the traffic they will have to carry in the near future.—Yours truly,

London, June 21st, 1900.

ROADSTER.

THE DANGERS OF PETROL.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—With reference to Messrs. Salisbury and Sons' letter in your columns of last week, we may say that in no way did we wish to suggest or imply that our fire was caused through the use of a Dietz automobile lamp. Our idea was to inform users of petrol the great danger there is with it. Our experience of the Dietz automobile lamp has been most satisfactory; in fact, we intend to use them on our other vehicles and locomotives, as they have proved the best for light and ordinary purposes.

Yours faithfully,

RICHARD DRAKE AND SONS, LTD.

Sutton, Isle of Ely, June 25, 1900.

THE TOLL QUESTION.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I write to warn any of your readers who may contemplate a run to Marlow *via* Cookham of the treatment they are likely to meet with if they wish to cross the bridge over the river at Cookham. On Sunday I ran to Marlow on my car *via* Maidenhead and Cookham. I was charged 8d. for crossing Maidenhead bridge, but was politely told that the charge included the return

journey and as many others in the day as I might choose to make.

At Cookham I found the gate closed, and after repeated calls a man strolled out, and, without any attempt to open the gate, said I had to pay 1s. 6d. I answered that I was perfectly ready to pay the correct toll, but asked him how he made up the charge, as carriages were charged 9d. He replied that I came under same charge as a traction engine, and if I didn't pay I shouldn't go through.

On my return I was kept waiting in the same way; a fresh demand of 1s. 6d. being made, and the man's manner was as insolent as he could make it.

It is bad enough to be compelled to pay an extortionate charge of 3s. for permission to cross the bridge; but when, at the same time, one has to put up with rudeness, it is quite sufficient to make one avoid the place in future.

My brother, who crossed the bridge in his car the same day, I find, met with a similar experience.—Yours truly,

LEONARD DOBSON, M.D.

59, Addison Gardens, Kensington, June 25th.

ELECTRICAL CABS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—One would think from reading the circular issued by the directors of the late London Electrical Cab Company, Limited, that the electrical vehicle was an impossibility, and that the vast sum subscribed by the public was used in endeavouring to put a practical vehicle on the streets.

From the manner in which the capital was spent, wicked-minded persons might feel inclined to suggest that the only reason for which the company was started was to obtain the £25,000 for the valuable (*sic*) licences, without which, we were told, you could not make electrical vehicles at all, although the electrical landau, which was shown to the would-be shareholders at Winchester House, was made under quite a different system, and one for which no licence was required other than that conveyed to the purchaser of any patented article.

The directors say that although the designs were approved of by engineers and experts, several defects developed themselves in the vehicles. To my knowledge the directors were advised to make only two cabs, in order to find out what was required to stand the London streets; but no, this would have been too prudent, and the licence money could not be paid out soon enough; so, without any actual experience to guide them, the first forty cabs were put in hand at once. They say they were too heavy for the rubber tires; of course 38 to 40 cwt., which was their weight, is too much for the same wheels and rubbers one would find on an ordinary four-wheel horse-drawn cab, which weighs only 8 cwt., and which were the sort put on the first cabs. The vibration, too, we are told, destroyed the cells. One cannot be surprised at the vibration in a vehicle which was built practically without springs; what further damaged the cells was the enormous amount of current taken from them owing to the want of attention to the gearing and sending out of the cabs without proper oiling arrangements. Not any of the vehicles had an ampere-meter, so that, however anxious a driver might be to run the cabs successfully, he had no certain means of telling whether his cab was running properly or not.

Then there was the driver bogey. Can one expect men who have a living to earn not eventually becoming disheartened and reverting to the old horse-drawn vehicle in consequence of the continuous breakdowns?—breakdowns which could in all cases have been prevented by proper supervision and examination of the cabs after each day's run. I know that it is possible to obtain any number of men who could, with slight training, properly drive an electrical vehicle. Consider again the large sum spent upon that alternating transformer plant, which was put down to supply the electricity for the accumulators, and which turned out to be practically useless, as the current ultimately cost 4d. or so a unit, and was abandoned, a continuous-current plant, with Babcock-Wilcox boilers, being afterwards put down, at a further cost of several thousand pounds, although all the current necessary for the undertaking could have been

obtained without a farthing outlay at about 1½d. per unit from one or two supply stations in London.

That electrical vehicles can be made to run, and at a profit, when properly managed, you have only to turn to New York, where, starting with a modest twenty cabs, the number is now increased to over 200, and to Berlin, where electrical omnibuses are in use successfully, and also to the few electrical Victorias which have been recently hired out here in London, and have proved such an unqualified success. But no company started to hire out electrical carriages can ever prove profitable if run upon the lines of the late London Electrical Cab Company.

That smart, comfortable and reliable electrical carriages will eventually appear in our streets in large numbers there is not the shadow of a doubt, their popularity is beyond all question. The entire absence of noise and vibration, heat, or unpleasant odours, not only to the passengers, but to anyone in the immediate neighbourhood, and the ease with which they are controlled, all tend to make them an ideal means of locomotion.

Yours truly,

The Automobile Club, S.W. CARL OPPERMANN.
June 23rd, 1900.

THE AUTOMOBILE ASSOCIATION'S CATALOGUE.

IN a very neat and effective cover comes the new list of the Automobile Association, Limited, which is not only dealing in motor-vehicles, but is also introducing the system of the French *garage*, viz., the warehousing and care of the cars of private owners. For an inclusive charge cars are stabled and kept clean, and as the warehouse is kept open day and night the cars are always at the disposal of their owners whenever they are wanted.

The cars illustrated in the new catalogue include motor-tricycles, quadricycles, Mors phaetons and dogcarts, the Delahaye voiturette, the Vallée car, the Orient Express phaeton, the De Dion-Bouton voiturette, the Holland dogcart, the Gobron and Brillié brake, the Koch paraffin car, the Hercules wagonette, the Swan and Ivan electric vehicles, the Peugeot victoria, and several others. We notice a design is given of the "University" runabout—a two-seated car on the Benz system, which will be ready shortly.

In addition to particulars of the vehicles there is a comprehensive price list of accessories and parts, and the catalogue, which extends to forty-eight pages, will be found useful to those on the look out for automobiles.

STIRLING'S MOTOR CARRIAGES, LIMITED, of Hamilton, are opening a show-room at 304, Sauchiehall Street, Glasgow.

At the last meeting of the Glasgow Corporation complaint was made as to the delay in delivering the motor dust-cart, ordered by the Cleansing Committee.

It is reported that the Daimler Motoren Gesellschaft, of Cannstatt, Wurtemberg, is building a new motor to the designs of Herr Maybach, engineering manager of the company. The new motor will be largely constructed of the new alloy "magnalium," and will comprise several special features, including mechanically-operated admission valves.

A TOLL-GATE keeper in Schenectady, N.Y., when called upon to collect toll for the first motor that went through the gate, settled the question of rates by the horse-power of the vehicle, "ten cents for a team and five cents for each additional horse," or fifteen cents, on the rider's statement that his was a 3-h.p. machine!

We met Mr. Hewetson, of Hewetson's, Limited, on Wednesday, and during the course of the few minutes we had with him he informed us that Benz cars were in greater demand than ever. Since the 1,000-mile Trial orders have been flowing in at an unusually rapid rate, "our only trouble," remarked Mr. Hewetson, "being that we cannot get the cars from Germany fast enough."

AUTOMOBILE RACING IN AMERICA.

[The Automobile Magazine.]

THE AUTOMOBILE WAGON FOR HEAVY DUTY.*

Concluded from page 294.

We have briefly touched on the matter of brakes, and this really is the nucleus of the speed question. We need only consider the speed of modern railway trains and ask ourselves whether such a speed could be safely maintained without the use of air brakes to approach the speed question of motor-wagons. It is an easy matter to provide for powerful brakes on a motor-wagon, and the propelling motor lends itself in many cases as a very powerful second brake. We have found that a load of three tons on a motor-wagon, running at a speed of eight miles, could be pulled up in eight yards, a performance which could never be obtained with horses. It may have escaped the notice of the on-looker that when we speak of an eight-mile gait with horses it should be asked, how long can they keep it up, and then it should be considered that it would probably only approximate a five-mile gait of a motor-wagon, which latter never gets tired, runs evenly, and is ready to do work as long as we provide fuel, and, further, is satisfied to remain where we leave it when put out of commission. The latter consideration is an economic advantage not to be overlooked in the operation of motor-wagons.

Taking up the different propelling agencies which have been experimented with so far, we find that almost every known motive power has been tried. Steam was employed as early as 1820, and such wagons were built by the world-renowned Ericsson and Tangyes in England, and even James Watt is said to have constructed a steam carriage. With the low steam pressures then available, poor roads, and difficulties with unreliable material and workmanship, it is not surprising that the matter was allowed to drop. The next experiments were in the line of oil engines, followed by electric vehicles, compressed air, carbonic acid and the revived steam carriage.

Naturally, in America, expectations were greatest with electric vehicles. The electric equipment renders a vehicle clean and easy to operate. These vehicles can be made to answer the requirements of running on smooth city roads. The suitable commutation of battery cells provided in these vehicles, effected through interconnection of contacts on the "controller," affords together with the series and multiple arrangement of the motor, some flexibility in the power and speed conditions of the machine. There are, however, inherent disadvantages to the use of batteries, which grow prohibitive in a motor-wagon intended to carry heavy weights over a long distance. It is common experience that on rough roads the punishment is more than the batteries can stand, and where we have a case of heavy loads to be carried, necessitating the use of steel tires, we can well say that at this phase of the evolution the battery makes the electric truck an impossibility. It would lead too far to enter minutely into the matter of cost of operating electric wagons, but it may be stated that the best traction cell has only a capacity of about seven watts per pound of its weight, and with this as a basis, one can soon calculate how much dead weight a wagon would have to carry to propel a big load over a long distance with one charge. The "maintenance" of batteries, apart from the actual cost of charging, is seldom spoken of, though it is perhaps the most serious item.

Next to the electric wagon we have seen the "auto-truck," or, rather, have heard about it. It was stated that compressed air trucks would soon be operated in considerable numbers. Now, while it cannot be denied that compressed air would make an ideal motive power, we have still to look for a complete revolution in the construction of light storage tanks to render this power available for trucks, granting that other disadvantages inherent to the use of compressed air can be practically overcome. Weight for weight, stored electricity lends itself more readily to the propulsion of wagons, since it will, as it were, "keep pressure" until it becomes well nigh exhausted, while the air pressure falls gradually as the air is drawn from the storage tanks.

Carbonic acid has also been proposed for the operation of

wagons, but it suffers in common with compressed air, and, moreover, the raw material to be compressed is by no means cheap. It has been proposed to compress illuminating gas, and use it for the propulsion of gas motor-wagons. This system has, however, the disadvantage of seriously complicating the mechanism.

A great deal of experience has been gained with oil-motor wagons, though chiefly in the line of light pleasure vehicles; and France, in which country there are many thousands of these vehicles plying, has led the world in their exploitation. As regards freight vehicles, however, no important results have been obtained with the use of explosive motors. A motor-wagon, on account of its great weight and peculiarity of operation, must have an abundant supply of power; so great, in fact, as to puzzle the uninitiated observer. We find that a load which can be easily negotiated by one horse calls for a power equipment equal to about 14 h.p. on the part of a motor-wagon. While we commonly understand that 1 h.p. equals 33,000 foot pounds per minute, we should consider how great the work of a horse can be for a short while on the race track, or when he becomes infuriated, and with "blind staggers" dashes into destruction. A horse, when required to pull a heavy load out of a difficult position, will not only jerk and lift the shaft so as to bring the wheels out of a rut and get them on a level, but will momentarily exert power which has been, by means of dynamometer, shown to be adequate to a performance of what we commonly call 14-h.p. Some people, in fact, assert that the horse can for an instant by far exceed the latter figure, but we may be well contented to accept this as a basis of calculation for the supply of motive power. The same horse, having pulled his wagon out of the difficult position, is able to modify the output of his energy, propelling the wagon at a good rate of speed as soon as he reaches better ground. The "speed-changing device," which should as nearly as possible emulate the peculiarity of the horse's muscular system, is still the greatest problem with designers of oil motor-wagons. The most ingenious devices have been already tried with a view of filling this gap, and with more or less success. An oil engine to run a motor-wagon cannot well be designed to vary in speed, at least not in a wide range, and be satisfactory in other respects. Its construction necessitates its running at a constant speed, whilst the speed requirements of the wagon wheels, to which it is geared up, are ever changing. Clutch and shifting gear wheels are, therefore, essential parts of every oil motor-wagon, and their operation, on account of the impact of the moving masses, often gives rise to serious trouble. Non-reversible, an oil engine is by no means a flexible motor. It will not start under load, and when it is in running condition it is very dependent on an even influx of its explosive mixture, and is liable to come to a dead stop without warning when its capacity has been suddenly overtaxed. Anybody who may have got stuck with a motor-vehicle while ascending an incline will appreciate these remarks. In such a case it will occur to him that it is very difficult at the same time to release the brake and start the wagon "ahead" on slow speed. It need hardly be said that an oil vehicle is dependent on the weather, inasmuch as the action of the carburettor is influenced by the atmosphere. This latter idea leads to the subject of perfect or imperfect combustion and its attendant outward sign, which is an evil-smelling exhaust. The good behaviour of large oil engines on heavy trucks after an extended period of running has not yet been satisfactorily proved, and the deterioration due to the pounding on the frame is a serious drawback. The general use and handling of large quantities of petrol at this stage of evolution of the oil engine is by no means free from risk of explosion, and there is some danger of affecting perishable goods and food-stuffs by the odour, which would naturally permeate them, particularly while standing at the express company's dépôt. If it were possible to make a practical success of an oil motor-wagon, using crude oil, no doubt the scope of the oil motor-wagon for heavy duty would be considerably increased.

Having thus described the difficulties with which the electric and oil wagons have to contend, we may devote ourselves to the steam wagon, with which, undoubtedly, important results have already been obtained. We have found the steam wagon superior to its competitors for the following reasons:

* Abstract of a paper read by Mr. A. Herschmann, before the American Society of Mechanical Engineers.

1. It has the greatest load and mileage capacity, or, in other words, radius of action. 2. Its operation is independent of charging stations, and supplies necessary for the operation of the wagon can be easily procured and taken aboard quickly. The operating expenses in the case of an electric (or, in fact, of any power storage system) vehicle grow to be prohibitive as soon as a certain ton mileage capacity is exceeded, tending to keep such an electric wagon small in size. In the case of an oil motor-wagon such economic restrictions to the size do not exist, and the objections to an oil motor-wagon of large capacity are more by virtue of difficulties in operation. With steam the case is altogether different. The tendency is here to build a large wagon, since with a steam-wagon the weight of the machinery to be carried does not grow even in an arithmetical ratio to the carrying capacity. One advantage found in the operation of a large steam wagon may not be apparent to the casual observer. In the case of the horse-drawn wagon one has to discriminate in loading it with goods which are to be delivered only on the exact route covered by the wagon, seeing that the daily carrying capacity of a horse is limited, while in the case of a large steam wagon this would be less important, since the percentage of operating expense due to the actual cost of propulsion proper is infinitely smaller than in the case of traction with animal power.

I believe that if the steam motor-wagon is given an unobstructed field and fair play, it will hold its own and oust the horse-drawn truck in short order. The change must come, and with, perhaps, the exception of the harness-maker everybody will benefit by it. The main trouble seems that educated engineers have so far had little encouragement given them to develop the motor-wagon, and that confused efforts of amateurs and stock-jobbers have drawn the attention of almost everybody to their work except that of the transportation community, who had no accurate data before them to judge of the practicability of the motor-wagon. Opinions will, however, soon be decided and converge on certain lines, and this once being the case many a designer will be saved from exerting himself in a wrong direction.

PRINCE AND PRINCESS RADIZWILL have been seen on a Hurtu motor-car during the last few days in London, piloted by Mr. Rush.

THE New Era Automobile Company has been formed at Portland, Me., U.S.A., with a capital of £60,000, to manufacture and deal in automobiles, motor-wagons, etc.

AT a meeting of the Bristol committee of the 1,000-mile Trial held on the 21st inst. the profits on the exhibition at the Drill Hall were announced as amounting to £33 2s.

THE receipts on the Beach and Torry motor-car routes, inaugurated at Aberdeen the other day, have, so far, exceeded the expectations of the promoters of the service.

MESSRS. BANKER BROS., Highland and Centre Avenues, Pittsburg, Pa., announce that they have acquired the sole United States rights in the Werner motor-bicycle.

THE distance of the run from Dublin to Killaloe which is to take place on July 14th is 108 miles. Although most of the cars will return on the following day some are going on a tour through Kerry.

THE steam motor-van supplied by Messrs. Julius Harvey and Company, of 11, Queen Victoria Street, E.C., to Messrs. Harmsworth, of the *Daily Mail*, is now running very well in the Manchester district.

THE Committee of the Automobile Club is in correspondence with the commissioners controlling the tolls of Goring and Cookham Bridges, with reference to the heavy charges of 1s. per wheel and 1s. 6d. per vehicle respectively charged for the passage of a motor-vehicle over the bridges above referred to.

A PROPOSAL has been mooted in New York to form a national association of automobilists, organised somewhat on the lines of the League of American Wheelmen, and with similar objects in view. Circular letters have been sent to a number of automobilists and manufacturers, and the replies are reported to be encouraging. It is stated that a national convention for organisation will be called before long.

THE BRITISH MOTOR COMPANY.

THE following circular, signed by Messrs. M. Lachman, R. W. A. Jeffery, S. F. Edge, H. G. Thomas and Gordon Hunter, who describe themselves as cash shareholders holding £69,184 in debentures, preference and ordinary shares, and representing a further £33,098, has been issued to shareholders of the British Motor Company:—

In consequence of a private meeting of some of the largest shareholders in the above company, who have paid cash for their shares, held on May 21st, the committee has been inquiring into the present position of affairs of the company and its future prospects. The result of this inquiry has disclosed a state of things so important that they think it right to lay the same with their views before the whole body of shareholders for their serious consideration, and now, therefore, do so as follows:—The company's issued capital is as follows:—Four per cent. mortgage debentures, £100,000; five per cent. cumulative preference shares, £151,568; ordinary shares, £800,000; total, £1,051,568. The company owns the English, and in many cases the colonial, rights to all the best known systems in existence for automobile and motor propulsion, including the Daimler and De Dion systems, and as the company has the right in many cases to all improvements in these systems they are constantly getting the benefit of fresh patents—for example, they get the benefit of all the latest inventions in connection with the De Dion and Daimler systems, many patents in which have been taken out even in the present year. They also, apart from the main systems, own such important patents as the float feed patent, which is used by all leading systems of motor-cars.

The company's receipts are obtained mainly from four sources, namely:—(1) Royalties from licences; (2) the sale of free licences; (3) the promotion of companies to work under licence; (4) the purchase and sale of motor-cars; and it might also in the future add a fifth source of income—namely, the manufacture of automobiles, voiturettes, tri-cycles, etc. Now, having regard to the extraordinary recent progress of automobilism in this country, which is now seriously beginning to follow the Continent in this respect, it is clear that the time has arrived when this company should be making large profits. There is now, for the first time, a very large demand for automobiles, which demand should get larger every day, and we might also refer to the extraordinary interest shown in the recent 1,000-miles Trial promoted by the Automobile Club, which has done a great deal to spread over the whole country ocular proof of the capabilities of the motor-car.

But although the company has opportunities for making large profits, we find (and this is our reason for communicating with the shareholders of this company) that it is doing no manufacturing and practically no merchant's business, and that neither is it granting licences, for the reason that it is unable to provide the money necessary for the purposes, including the money necessary to protect its patents, by proceeding against numerous infringers mainly in the persons of importers of foreign-made cars. Under these circumstances it appears to us either that the shareholders must be content to stand by and let the company's business continue to depreciate, or they must make up their minds to find money to protect the patents, with a view to the sale of licences, and to enable the company to do a merchant's, and if necessary a manufacturing, business.

But if the shareholders do this, we, who are among the largest, think, as no doubt they will think, that concessions should be obtained from (a) the holders of the vendors' shares, who practically control the voting power of the company, but whose shares cannot become of any great value unless money is found, and (b) the debenture holders, whose security likewise cannot become of any great value unless the shareholders find money. The committee have, therefore, approached the parties in question, with the result that the following arrangement is suggested:—

A new company to be formed on the following lines:—Five per cent. mortgage debentures, £50,000, to take the place (by consent) of the existing £100,000 debentures; 5 per cent. cumulative preference shares, with a right to one-half of the further profits up to a further 5 per cent., £500,000. These preference shares will take the place of the £151,568 preference shares and the 300,000 ordinary shares held by others than the vendor.

The remainder of the shares representing the vendors' interest becoming deferred and receiving the remainder of the profits. The debenture holders, in consideration of the preference and ordinary shareholders putting up more money, to take a 5 per cent. 10s. debenture in place of a 4 per cent. £1 debenture. The preference and ordinary shareholders, other than the holders of the vendors' shares above referred to, to amalgamate and be entitled to exchange their shares for an equal number of preference shares in the new company, credited with 17s. paid, and having a liability of 3s., equivalent to a cash working capital of about £66,000, of which not more than 1s. (or about £22,000) should be called up in the first instance, and certain safeguards as to the calling up of the balance to be arranged.

The preference shareholders by this arrangement will get a more marketable share than that which they hold at present. The Board of the new company to be also re-arranged with the approval of the shareholders. If a scheme somewhat on the above lines can be put through, we should have no hesitation in recommending shareholders to pay up the 1s. assessment, and need hardly say we should certainly do so ourselves. In order that no more time may be wasted we have asked the directors (a) to call the shareholders together at once; (b) to get the accounts made out and audited; and (c) if sending out proxy forms, to send out one addressed to members of this committee, so that share-

holders, if they wish, can send their proxies to us, which we should strongly recommend them to do. From one source an offer has been received to underwrite the assessment on 300,000 shares at 1 per cent.

ASSAULT ON A MOTORIST.

IN the Court of Queen's Bench, before Mr. Justice Ridley and a Common Jury, the plaintiff, Mr. Robert Moffat Ford, the managing-director of the Motor-Car Company, Limited, of 168, Shaftesbury Avenue, has sued the Managing Committee of the South-Eastern and London, Chatham, and Dover Railways to recover damages for assault. It appeared that on December 20, 1899, the plaintiff went to Victoria Station to fetch away a motor-car which had been sent from Brighton. As he was leaving the station yard a boy threw a stone at the machine and it struck plaintiff in the eye. He dismounted, ran after the boy, caught him, and brought him back to the yard. A crowd assembled, the cabmen taking the part of the boy, and calling out that plaintiff had got the wrong lad. Plaintiff asked one of the station constables in the employ of the company to take the name and address of the boy. He was asked to take his machine out of the yard because it was suggested he was causing an obstruction of the traffic, and he said he would do so immediately the name and address was given or if a constable would hold the boy. Ultimately, according to his case, he was half lifted and half pushed out of the yard, and his motor-car was pushed out after him. This was the assault complained of. For the defence it was suggested that the company's constables, who were not sworn in, had no right to detain the boy, or to take his name and address, and that as the plaintiff was causing an obstruction, his motor-car was removed, and a servant of the company put his hand upon his arm, and left the place.

Mr. Justice Ridley, at the conclusion of the plaintiff's case, held that there was no question for the jury. The plaintiff had put upon the constable a condition that he should do that which he had no right to do, and as there was no suggestion that more violence than was necessary had been used in removing the plaintiff, he saw no cause for action. Judgment was therefore entered for the defendants, with costs.

FURIOUS DRIVING CASES.

MR. FREDERICK WILLIAM YOUNG, of New Oxford Street, was summoned by the police last week for driving a light locomotive, a motor-tricycle, at a greater speed than was reasonable and proper, having regard to the traffic in the highway. It appeared that on the 9th inst., the defendant was seen driving in High Road, Chiswick, in the direction of Kew, at the rate of eighteen miles an hour. Police-constable Alker, 517 T, who was in plain clothes riding a bicycle, said he followed the defendant over a mile. The Magistrate: At the rate of eighteen miles an hour? The Constable: Yes. The Magistrate: Very good work. (Laughter.) The constable further stated that the defendant increased the speed at Gunnersbury station. On nearing Kew Bridge the defendant was stopped. The defendant said the object of increasing the speed was to clear himself of cyclists who followed him. Mr. Lane remarked that cyclist objected to motors snorting and puffing along the road. He fined the defendant 5s., with 2s. costs.

AT the Bournemouth Borough Police Court last week Mr. Arthur Norman was summoned for furiously driving a motor-car on June 9th. James Thomas Jellicoe, a retired officer in the Indian service, stated about mid-day he was riding a bicycle up the Old Christchurch Road, and when near Holy Trinity Church he saw a motor-car driven by defendant coming down. As they neared defendant turned the car to the wrong side of the road as if to collide with him. Witness was forced off his bicycle and fell across the pavement. The handles of the machine were bent, and he received several bruises. The defendant then turned the car away and went on. Charles Francis Watson, who witnessed the occurrence, stated the machine was travelling about fourteen miles an hour. P.S. Littlewood stated on measuring he found the car went within ten inches of the kerb. Witness stated defendant told him a 'bus was in the way. Defendant stated he was behind a 'bus. The vehicle pulled up and he was obliged to turn out sharply to avoid striking the back. The accident then occurred. Superintendent Foster said the defendant was a very careful driver, and he was surprised to find him in that position. The Mayor said they were unanimous in convicting. The motor-cars did go at too great a pace down through the town, and defendant had better by far have erred in judgment by not going fast enough than to endanger the lives of people, whom they (the Bench) must protect. They did not want to be harsh with motor-car drivers. All they wanted was for them to do what was right and just. Defendant would be fined £1 inclusive, and he hoped it would prove a warning to all drivers.

AT Warwick Police Court on Monday, Mr. Frank Wilson, 5, St. Peter's Street, Bedford, was summoned for having about noon on June 12th furiously driven a motor-quadracycle, in West Street. P.C. Troman said defendant was coming from the direction of Stratford-on-Avon. He was driving, but there was another man on the front. They were going from twenty to twenty-five miles an hour when he first saw them. Witness put up his hand for them to stop, but they took no notice until they got to the West Gate. He told defendant he was going too fast—from twenty to twenty-four miles an hour—and he admitted it. Wm. Cooke, landlord of the Nelson Inn, said he should think the speed was quite twenty miles an hour. Defendant said it was a small engine, and it was impossible for it to go up the hill at that rate. The engine was revolving rapidly, but the machine was not going quickly. He stopped as soon as

he got to the top of the hill, although he could have got away with ease had he wished. He asked the Bench to see the motor-cycle, and ride one, to show the impossibility of ascending the hill at that speed. The Mayor: I don't care to risk it. (Laughter.) The Bench were of the opinion that at the bottom of the hill, when the policeman first saw him, defendant was going faster than he should, and ordered him to pay £1 ls., including costs.

AT Portsmouth Police Court on Monday, Mr. John Adolphus Koosens appeared to answer a summons for driving his motor-car at a furious rate. Detective Moth, accompanied by P.C. Wombell, saw defendant in his car going about seventeen miles an hour, between Clarence Esplanade and Eastney Barracks. The defendant pleaded not guilty, but had no witnesses to call. The Bench imposed a fine of 5s. 6d., with costs 9s. 6d.

AT Thetford Petty Sessions, on Monday, Mr. W. J. Boughton, builder, of King Street, was charged with furiously driving a motor-car in Guildhall Street, on the evening of Whit Monday. Mr. Day appeared for the defence. Police-sergeant Wilkin said about 8 p.m. he was in the Market Place, and saw defendant coming from Guildhall Street driving his motor-car at the rate of ten to twelve miles an hour. He slackened down to four or five near the post-office. There were a lot of people about, and the Salvation Army procession was going down King Street. Defendant followed, and kept on the near side of the road, and in passing knocked two women down, both being very much hurt. Police-constable Goodbrey and witness went to their assistance. He spoke to defendant, who said he was not on the wrong side of the road. He could not help it, as the people ran in his way. Cross-examined: Witness said defendant slackened speed in King Street. One of the women was knocked down in front of the motor-car, and the other got a knock on the ankle. Police-constable Goodbrey corroborated, and added that he heard Mr. Boughton, jun., tell his father he was not on the wrong side of the road. Cross-examined: The two women were in the procession. They had no chance to get away, as the car alarm bell was sounded near the market, and the occurrence took place opposite Mr. Green's shop. Mrs. M. A. Hensby said she was in the Salvation Army procession walking with Mrs. Crane very quietly. The motor-car knocked her down on to the footpath, and she was unconscious. It struck her on the back. She heard no alarm given. Mr. Day called defendant, who said he was only going four miles an hour. As soon as he saw the Salvation Army he slackened to one mile. He said there was a clear passage on their left and proceeded very slowly down with brakes fully applied. The two women rushed out of the procession and got pushed down. There was no room to pass on the other side. He considered he used all the precautions necessary. The Bench after consultation decided that the police were fully justified in bringing the case for the protection of the public, and in future the utmost care must be exercised in driving through the streets. They would inflict no fine, but defendant must pay the costs, 16s.

JOHN G. BROWN, cycle agent, was also summoned for furiously driving a motor cycle down Castle Street, on June 11th. Mr. Day defended. Police-sergeant Wilkin said he saw defendant coming down Castle Street just before seven o'clock at the rate of fifteen or sixteen miles an hour. Witness held his hand up and he slackened to ten miles an hour, and went down King Street. Witness followed and told him he was going too fast. He admitted going twelve or thirteen miles an hour, and said he was in a hurry. Cross-examined: There were no vehicles about, but there were several people. Defendant said he was not going at the rate of fifteen miles an hour. He thought he was going twelve or thirteen miles an hour, and rather faster than usual, but after consideration he did not believe he drove so fast as that. The Bench said they must convict for public protection and fined defendant 5s. and costs, and cautioned him against driving so fast in the future.

REFUSING TO STOP.

AT the Windsor Petty Sessions last week, Mr. Alfred Rawlinson, of 21, Ovington Square, London, was summoned for refusing to stop a motor-car he was driving on May 25th, when requested to do so in the usual way by Mr. Augustus Peppin, who was in charge of a restive horse. Superintendent Carter stated that defendant had written asking for an adjournment as he had been unable to get two witnesses for that day. The hearing was adjourned for a fortnight.

THE Motor-Car Journal.

Vol. II.]

LONDON, SATURDAY, JULY 7, 1900.

[No. 70.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

TOGETHER with the tables published in these pages on June 16 the report of the Judges' Committee appointed by the Automobile Club in connection with the 1,000-mile Trial which appears elsewhere in this issue will present our readers with a full record of the performances of the competing vehicles. The general conclusions are confirmatory as to the steady progress of the automobile

industry in this country, but, while not going into detailed criticism of particular vehicles, something further might have been said as to the causes of failure—so as to have given useful advice to manufacturers in their future experiments. Very rightly do the judges call attention to the fact that some competitors neglected the rules laid down by the Club. Such lack of adherence to regulations will probably lead to disqualification in future competitions. Eight drivers are commended for their respect for the rules within the controls. The gold medal for the best vehicle has been awarded to the Hon. C. S. Rolls, and in the private owners' section ten silver medals were given. Mr. Kennard's 8 h.p. Napier won the silver-gilt medal of the Automobile Club de France, and the silver cup presented by Mr. Ernest Owers has gone to the Hon. C. S. Rolls. In the manufacturers' section the Benz Ideal, Locomobile steamcar, New Orleans voiturette, Wolseley voiturette, Motor-Car Company's Triumph, De Dion voiturette, the Daimler Company's cars, the Motor Manufacturing Company's cars, the Ariel quadricycle, the Ariel tricycle with Whippet trailer, and the Century tandem attained distinction, as did some others that were entitled to the *Daily Mail* prize for vehicles successfully completing the journey. The report should furnish interesting matter for a meeting of the Automobile Club in the winter.

A Motorist not Convicted.

WHENEVER a motorist appears in a police-court charged with driving at a speed not appreciated by a policeman he may usually expect to be convicted, fined, and threatened by the magistrate. Therefore we would congratulate Captain Langrishe on having been acquitted of such an offence when he was summoned to the West London Police-court the other day for alleged furious riding on a motor-tricycle. The policeman said he heard a hissing noise, but it was clearly proved that the compression tap was open, and that the captain—who is a J.P. for Kilkeny, a master of hounds, and who also drives a four-in-hand as well as a motor-car—was pedalling at the time he was committing the alleged offence. Mr. Staplee Firth defended and the Hon. C. S. Rolls was prepared to give his testimony but was not called. Strange to relate, the case was actually dismissed.

A Forty-mile Drive.

ON Thursday last our yellow car—which, by the way, is pulling remarkably well just now—was driven to the Fair Mile, on the Ripley Road, and back. In the course of the run more than thirty cars (mostly voiturettes) were counted. Many were in and about town, several were in Hyde Park, including a French Panhard with a glass screen in front. The run to the Fair Mile is a favourite one with the ladies of our party, as a stop can be made by the common to pick the wild flowers and heather, which grow so luxuriously on this favoured spot. Notwithstanding the recent heavy rains the roads were very dusty.

Under the Hammer.

THE first great automobile auction in this country was held on the 29th ult. by Mr. Ernest Owers, at Messrs. Taylor and Town's livery stables, near the Finchley Road station (South Hampstead) of the L. and N.W.R. The locality is a capital one for such a sale, it being but a short ride from Baker Street station, and the venue was admirably adapted to the purpose. Mr. Ernest Owers is an automobilist himself—the owner of a Parisian Daimler car—and was able to include thirty-two vehicles in the first of his automobile sales. These he proposes to hold monthly, and as the enterprise becomes known he hopes to see a large attendance of private as well as trade buyers. Naturally the gathering on the 29th ult. was largely composed of those in the trade, and to give the names of the gentlemen present would be a catalogue of all the names familiar in the commercial circles of the London automobile industry. In addition there were several enthusiastic automobilists.

Sales and Prices.

RECOGNISING the character of the company, Mr. Owers had no need to dilate upon the advantages of automobilism. The first lot was rather old-fashioned—a 3 h.p. electric "Sherinette" car to seat two persons—and it was regarded as somewhat of a curiosity. Lot 2 was a similar car, and fetched £18. A 4 h.p. electric victoria, with a body that was built for the Queen of Spain, realised £47 10s., and a 3 h.p. Daimler-Peugeot mail car to seat two persons and fitted with an Estcourt patent cooler was sold at £60. The two succeeding lots were 2½ h.p. motor-tricycles, made by the Motor Manufacturing Company, each of which was sold for £47 10s. A 5½ h.p. Daimler victoria having failed to attract a purchaser, a motor trade van in a very rough state was knocked down at £4. Several lots were unsold, these including two 6 h.p. Daimler phaetons fitted with Estcourt's patent cooler, a motor brewer's van, a French voiturette, and some motor-tricycles etc. In addition to those already mentioned, the other sales included a Benz car at £117, and a 6 h.p. Daimler wagonette to seat seven persons, which resulted in the best bid of the day, viz., £235. Chatting with Mr. Owers after the sale, we learned that the opportunity for trial trips during the two days prior to the event had been

well used, nearly every car having been out three or four times. The next sale will be held on the 28th inst., when a varied catalogue should prove attractive.

Angling and Automobilism.

HUNTING, racing, touring, and pleasuring generally will all bring the automobile into requisition, and we notice that the quiet, peaceful pursuit of angling is being facilitated by the motor-car. The *Field* gives a case in point. A well-known automobilist, Mr. C. Johnson, who is also fond of angling, left his flat on a recent Saturday afternoon, and drove his 6 h.p. car to Wheathampstead for the evening rise. He slept there, but sent the car back to town by his man. The next morning the latter drove the owner's wife to Henley, by way of Cookham and Great Marlow, and after lunch brought the lady back to town. The man then went off to Wheathampstead, and the owner drove the car back to London the same evening. To the angler especially such independence of train service is invaluable, for the lateness of a train, or the absence of one at a suitable hour, may cause him to lose the best of the fishing. Another performance of the same car may be chronicled with advantage, as illustrating its mobility. The owner left Cambridge with a friend one morning, at ten o'clock, and drove across country to Oxford, and thence to London. They had about two hours for meals *en route*, covered 150 miles of road, and arrived in town in time for dinner at eight. Such freedom of movement is in marked contrast to the limitations of the horse-drawn vehicle.

Cars at Worthing.

At the annual licensing meeting of the Worthing Town Council applications were received for licences for fifteen stage carriages, five omnibuses, sixty landaus—all drawn by horses; twenty-five pony chaises, four saddled asses, nine goat chaises, and two motor-wagonettes. Thus two mechanically propelled vehicles were desired as compared with 118 carriages, etc., drawn by animals. And although the disproportion was so great Councillor Ovenden moved an amendment asking the General Purposes Committee to reconsider its decision to recommend the renewal of the licences to Mr. A. H. Collis and Mr. A. Palmer for their motor-wagonettes. This was seconded by the Mayor, Alderman Parish. Fortunately the Council recognised the injustice of the proposal, and by a large majority consented to the licence being granted. And so Worthing will continue its patronage of the automobile.

French Enthusiasm.

FRENCHMEN are not only enthusiastic with regard to the pastime of automobilism, but they can also become enthusiastic in the pursuit of automobilists. The other day the employee of a motor-car establishment near the Bourse took a trip on a car, going along the Rue Réaumur at a break-neck speed. He knocked a pedestrian down, and continued his pace unslackened. Those who saw the incident chased the automobilist, who was stopped by a block in the traffic at the corner of the Boulevard Sébastopol. There his pursuers seized him, tore him from the machine (which the bystanders proceeded to smash, ultimately pouring the petrol over the frame, and setting it on fire), and beat him with fists and sticks. Then he was handed over to the police, and is to be charged with furious riding. Such incidents should do something to cause a slackening of the speed which has apparently increased the risk of accident in the streets of Paris.

Meet at the Ranelagh Club.

AN automobile gymkhana will be held at the Ranelagh Club, Barnes, S.W., on Saturday, the 14th inst., entries for which are to be sent to the Secretary of that club not later than Thursday morning next. The entries are open to members of the Ranelagh and the Automobile Clubs, and the wise

provision has been made that no second prize will be given unless there are five entries. The full course is about half a mile over the grass, and there will be six events. There will be a ladies' race, for which Mrs. Kennard and Miss Weblyn have entered, a bending race for motor-carriages, an obstacle race, a starting and stopping handicap, a motor-tricycle coat and waist-coat race, and a contest for vehicles with tube ignition only, in which the driver is to start on foot twenty yards to the rear of the carriage, run to the vehicle, light the lamps, start the engine, and race round the full course. Acting on a suggestion made by the Master of the Rolls, an arrangement has been made by which members of the Ranelagh Club may send their horses to Ranelagh on Saturday morning next to be trained in the presence of motor-cars.

The Bachelor's Chance.

AMONG the advantages of automobilism that indicated in the following advertisement from a daily paper has hitherto been overlooked:—"To Motor-Car Owners.—A lady will give board and lodging at a lovely seaside place to anyone who will bring their motor-car and give use of it for a few weeks. Most popular place. No other car. Many visitors. Good change of air for manager of a company.—Address, —, —." The possibilities involved in this connection are manifold. Firstly, the owner of a car may secure board and lodging in return for the pleasant privilege of taking his landlady out for a drive. That is the suggestion that will be made by some. Others, however, will see in the advertisement the possible opening for a good motor-vehicle service. There is no car at present in the place; or, to express it another way, there is no rival in the field. There are many visitors; it is a popular resort; and if it would be a "good change of air for the manager of a company," it should prove reinvigorating and refreshing for a director or anyone else who has a car. Sir Francis Jeune may make a note of the advertisement to utilise in his next speech on the blessings of automobilism and the opportunity it presents for the cultivation of friendship and sociability.

Registered Competitors.

AUTOMOBILISTS intending to take part in competitions should register themselves with the Competition Committee of the Automobile Club. Up to the present time the following gentlemen have done this:—Messrs. R. Moffat Ford, E. Campbell Muir, A. E. J. Steele, Stanley Lambert, Victor Lee, E. Buck, S. Rowbottom, F. F. Wellington, C. Machin, C. Jarrott, J. Cusins, Claude Johnson, Mark Mayhew, S. F. Edge, Harvey Du Cros, Hugh Weguelin, and Harry Lee. The following are the cars and motor cycles which have been registered:—16 h.p. Napier car, 2½ h.p. Ariel tricycle, and 6 h.p. De Dion tricycle, S. F. Edge; 80 mm. Ariel tricycle, Harvey du Cros; 6 h.p. De Dion tricycle, C. Jarrott; 2½ h.p. Gladiator tricycle and 7 h.p. Phœbus tricycle, F. F. Wellington; 80 mm. Ariel tricycle, J. Cusins; 2½ h.p. De Dion, De Dion Syndicate; Iveagh Phaeton No. 299, Motor Manufacturing Company; 3½ h.p. Delaugere tricycle and 8 h.p. Panhard car, Mark Mayhew; 6 h.p. Daimler Parisian, Claude Johnson; Simms Motor Wheel, Motor Carriage Supply Company; M. M. Company's Panhard, Motor Manufacturing Company; Strickland tricycle, A. E. J. Steele; Comiot tricycle, Stanley Lambert; M. M. Company's 3½ h.p. tricycle, Motor Manufacturing Company; 12 h.p. Panhard, Hugh Weguelin.

The National Trust.

PARLIAMENT not having seen its way to protect places of general interest, the National Trust for Places of Historic Interest or Natural Beauty—could not a shorter title be found?—is performing a work that should commend itself to automobilists in common with others who delight in the scenic glories of the country and the historic associations of notable buildings. During the last twelve months the Trust has rescued several places of interest, including fifteen acres of wooded hillside at Ide Hill

Kent, and Wicken Fen, as well as Kanturk Castle, county Cork. It is now desired to raise £350 for the purchase of the old courthouse at Long Crendon, Buckinghamshire, and £200 for the old post-office at Tintagel. The preservation of such buildings is desirable in more ways than one; but our readers will mainly recognise the increased interest the presence of such historic structures gives to their trips in the country.

A 100 h.p. Motor-Car.

A MOTOR-CAR with a motor of 100 h.p. is now an actuality, if *La France Automobile* is to be believed. Our contemporary, a member of whose staff has seen the car at a distance, states that it is a Peugeot, the engine having eight vertical cylinders. The vehicle, which belongs to M. Lemaitre, is fitted with an aluminium body and 150 mm. pneumatic tyres. It is to be subjected to trial shortly, the results of which will be eagerly awaited.

In Essex.

HAD Alderman Bond, of the Chelmsford Town Council, been one of the party who journeyed from Chelmsford to Burnham-on-Crouch the other day he would probably have restrained his feeling of alarm at the pace of motor-cars. At a recent meeting of the Council he said, "something ought to be done to prevent that sort of thing," i.e., the speed of cars. The Association of Old Chelmsfordians, however, are less nervously inclined, and held their summer meeting at Burnham-on-Crouch, whither they journeyed, some on cycles and others on a motor-car lent by Mr. C. P. Knights, and also a Daimler wagonette. Later, some of the party went on to Southminster. The trip was a capital one.

The Automobile and War.

If it takes the British public one generation to grasp an idea, how long will be required to get a reasonable notion into the War Office? That is a conundrum propounded some months ago, when the suggestion was made that the adoption of the automobile in connection with the transport service in South Africa would have been of considerable advantage. Even now the lesson has not been appreciated by the military authorities. The few experiments that have been made with traction engines, however, have had a good effect, and we note that 900 marines just sent off to China are accompanied with a traction engine to haul the guns. With so many disturbing elements in the international outlook the authorities at home should watch and encourage the development of automobilism as a means of assisting the army.

A Motor-Car as a Shooting Box.

THE *Durham Chronicle* thus records an incident which has lately taken place in one of the streets of the ancient city: "A large motor-wagon, of a type built to the order of the Government for the carriage of mails in some of the country districts, by way of experiment, was being driven over Elvet Bridge towards the Market Place, and on reaching the steep ascent opposite Mr. Jeckell's tobacconist's shop the big machine came to a standstill, the wheels evidently failing to grip the granite setts. Several attempts were made by the driver to reach the top, but without success, the traffic meanwhile being blocked at both ends. On taking off the brake to make a further attempt, the wagon began to run backward. Unfortunately, a dozen yards behind the car was a small cart carrying two four-oared racing craft belonging to the Tyne A.R.C. In his efforts to keep control of the machine, the driver turned it into the gutter directly opposite a public-house. The result was that the bows of the boats were crushed between the back of the car and the house side, causing damage to the craft to the extent of some £20. But for the gutter and the projecting signboard, which acted as a buffer, there is every reason to believe the car would have backed through the public-house window. It is said the car belongs to

a gentleman who intends using it as a shooting box during the coming season, and was on its way north."

A Klondyke Story.

SOME time ago we announced that MM. J. de Lamare and R. Merville intended to journey across the Klondyke region in an automomile. They have made the trip from Fort Bennett to Forty-Mile River in four months, and M. Lamare has been telling a pressman of his adventures. "There were many rough places where we could not run the machine," he said, "but most of the way we were able to do so. We were followed by a sledge drawn by oxen, on which were the supplies and the gasoline for the automobile. We would go ahead in the motor-car as far as we could and then wait for the sledge and replenish our supply of gasoline. Once, while crossing an unusually rough pass, we broke one of the supply tubes of the machine and were forced to take a tow from the sledge. Fortunately, however, there was a blacksmith's shop in the Chilcoot Pass. At another time we were so far ahead of the sledge that we were without food for more than fifteen hours. Our longest day's run was 110 miles. Most of the runs fell far short of that figure. We had with us an arrangement of skates to fasten to the machine in crossing ice. We were not obliged to use them as we found the automobile could run well on the ice where the snow was not too thick. The ordinary rubber tires held excellently, and kept the car from slipping. We visited Tagish Lake, Marsh Lake, Aplin Lake, and Taku. Some of the people who had never

A 12 H.P. TWIN DAIMLER CAR.

seen an automobile looked on the machine with awe and wonder. At Fifty Mile River we turned back because we found the river open. Our large automobile we left behind us, but we have still in our possession the light electric machine we had with us."

Motor-Cars and Market Gardeners.

WITH the advent of the fruit season that well-known gooseberry, the sending of fruit by motor-car, has again received attention in the London Press. The idea is, of course, quite feasible, and if adopted would prove very economical, but we have not heard of it having got beyond the point of suggestion. Seeing what is being done in connection with the Heavy Traffic Trials at Liverpool, might it not be possible to promote something of the kind in the south of England? In the market gardens round London there ought to be many good opportunities for utilising the motor-car in bringing produce to the metropolitan markets.

THE Automobile Club is organising a three days' trial of electrically propelled vehicles for the 1st, 2nd, and 3rd October next. At the same time it is proposed to carry out some tests of the horse power of motors and the horse power given off at the road wheels of automobiles.

A RUN TO GUILDFORD.

BY "WHYBROW."

ACCORDING to many, automobilism is associated with all the delights and the glorious uncertainty of other sports. You decide to journey by motor-car, and once aboard the chances of reaching one's destination are variable. Such is the opinion long held and now being quickly dispelled. Driven from their opposition on that ground, opponents of the motor-car talk glibly of its noise, vibration, evil perfumes, and other matters which have been associated with such vehicles in their primitive stage of development, but which are now only found with the more antiquated vehicles; for the development of the industry is proceeding rapidly, and the motor-car is going fast.

The other day I accepted a seat on the boiler of a Locomobile—about as comfortable and reassuring a position as one could wish. The modern journalist has to encounter risks both at home and abroad, and some of my colleagues kindly offered to watch for me from a balloon should I be sent high into air on the journey. They have since seemed disappointed that I did not visit them in their elevation; but I stuck to the car and returned home whole. More than that, I am convinced that the fears of those who pretend to fancy there is risk in a steam vehicle are about as groundless as the alarm of the old lady who declined to

go into the subway in front of the Mansion House because she did not know where the steps ended, and said she preferred this mundane earth to a dark dip into an unknown futurity.

Anyhow, I have done the deed, and if "Whybrow"—to say nothing of several dukes and others who own Locomobiles—could trust himself on such a vehicle, who need fancy mishap! With Mr. H. N. Searles at the helm I left Sussex Place, South Kensington, on a Locomobile the other afternoon at 2.15 p.m., ten minutes having been occupied in getting the car ready. The day was bright and the sun shone out with a determination that did him credit. There was a bit of a breeze blowing, and over the wood pavement we went in and out the traffic with an ease and grace not usually associated with mere mechanical things. Within a quarter of an hour we had the Thames to the right and left, and then into the High Street, Putney; up Putney Hill we went behind a wretched pantechicon that "dragged its weary length along" and caused us to follow slowly. The sharp easing of speed as we drew close to the van showed the obedient character of our vehicle, and then seeing a safe chance of going to the front we veered to the right, and in a few seconds were back on our own side of the road and quickly finished the ascent. After a good run along a level road we came up with a quadricycle, and then while passing Wimbledon Common saw the steam delivery van of a great London firm coming our way. That and a wagonette on the Benz system that we met at Barnes on the return

journey were the only automobiles we saw—a rather rare occurrence on that popular road. We were going along steadily and running without any perceptible vibration. In fact, I had already proved two things to my satisfaction—viz., that the Locomobile is an excellent car for either doctors or invalids, as the latter feel no vibration and the former can have the car ready for immediate running by the application of an idea which Mr. Searles told me has been adopted by the head of the Fire Department in New York. That gentleman goes to fires—not in a cabas is frequently the case in older and more traditional London, but on a Locomobile. A small gas jet is kept burning so that there shall be no delay in getting about his business.

But I am leaving my road, which lay through Norbiton and into Kingston, where we came in view of the Thames again two or three minutes over half an hour after crossing it at Putney Bridge. So far we had had 18lbs. air pressure in the petrol tank, and that was not exceeded the whole of the way to Guildford. In fact we went from Ripley to our destination with an air pressure of only 15lbs. Leaving the ancient town of Kingston we were quickly into Ditton where the quietness and solitude were very different to the animated scene always to be found there on Sunday mornings. And then leaving Sandown Park racecourse on the right we went into Esher, and turned into the yard of the Bear for water, as the tank, which has a capacity of fifteen gallons, had only been half-filled at the start. A full drink having been given our car—an operation which would have been more quickly performed had a hose been provided, as is done at some of the hotels on the road—we resumed our journey with cheerfulness. The scenery was delightful, and around Esher the flowers seem particularly rich and varied, while the ferns clustering around the trees on the heath and woodlands presented a wealth of foliage that added to the enjoyment. Mr. Searles came to London from America last August, and leaving again towards the end of the year returned to England in January. He is delighted with the pleasant lanes of Surrey, and enraptured with the good roads that abound—so different to the ill-conditioned highways of usually wideawake America. We had had a steady breeze which developed strongly as we crossed Esher Common into Cobham. Just before reaching the wide street of the latter place motorists and cyclists were warned to drive slowly as there was an open trench at the side of the road. So far we had met few carriages, but just before reaching Ripley—which we did at five minutes to four—a coach-and-four gave us some entertainment. Quite three hundred yards away one of the leaders was restive, and the grooms were endeavouring to hold its head. Frantically it passed, and we then encountered a strong head wind the rest of the way. At seven minutes past four we were four miles from Guildford, where we arrived at 4.20 p.m.

Descending the hill into the town we put up at the Angel, where the water supply was replenished, and the requirements of mortal man attended to in the hotel itself. The combined operations took time, and while the air pressure was being pumped up to 35lbs., I had an inspection of the car, which was fully described and illustrated in the *Motor-Car Journal* of December 8th. Not only is the general appearance good, but the ingenuity of the design is shown even in the sheet of leather suspended from the seat in which are placed, in proper position, the various tools required for tightening nuts, cans for lubrication, etc.

At five o'clock we passed through the Angel yard, and turning to the left went to the front of the hotel and up the steep hill in grand style. It had been market-day at Guildford, and the droves of sheep and cattle seemed to have had a good education in proper behaviour in the presence of motor-cars. The cattle regarded us with nonchalance and the sheep with less timidity than appeared natural—probably owing to the quiet and easy going of our vehicle. Thanks to the increased air pressure, a good speed—quite up to the legal limit as they were wont to chronicle on the 1,000-mile Trial—was obtained, and we got to Ripley by a quarter past five, where we filled the water tank, and prepared for a non-stop run to town. On the way several carriages drawn by horses and driven by men who were more nervous than their animals were passed, and so good was the running of the car that

we got to Esher just after six o'clock and were in Kingston an hour after leaving Ripley, where we had spent quite fifteen minutes. As we steamed along by the Thames the coolness of the evening was apparent, and there was almost a wintry aspect as we went through Richmond Park, where two or three little short stretches of newly laid road were met with. Out of the park and along Priory Lane into the Upper Richmond Road Mr. Searles directed his Locomobile. Then skirting Barnes Common we were over Hammersmith Bridge by ten minutes to seven. As Bridge Road was being repaired—a piece of good news to cyclists and motorists alike—we turned to the left and thus into the Broadway, and in a few minutes had reached Sussex Place again. With the help of a man we raised the vehicle from the side roadway into the show-room, and my afternoon's experience was at an end. If asked to give my opinion of the Locomobile I should say it is a capital car for a day's run at a pace to allow the passengers to revel in the beauties of the country, and that is, as Sir F. Jeune has observed, one of the great virtues of the automobile. There is only one disadvantage about such a trip as that I have chronicled. Everything went so well and without a hitch that there is little to describe save a continuance of pleasant reliable running. Still to the ordinary unjournalistic person that is something deserving consideration.

THE New York Motor Vehicle Company has been registered in New Jersey, with a capital of £100,000.

ON Saturday last two motor-wagons belonging to the Newcastle branch of the Co-operative Wholesale Society were on exhibition in Green Street, Sunderland.

A CLUB badge has been designed and will soon be executed for the members of the Automobile Club of America. A wheel entwined with a ribbon bearing the name of the club is the design adopted.

AN automobile will run between Onteora Park and Tannersville, N.Y., this summer, for the purpose of carrying the Onteora Park mail.

THE numerous complaints in the newspapers by persons whose horses have been frightened by motor traffic on country roads are, says the *Western Mail*, the most significant evidence of their increasing popularity.

A MEMORIAL is to be presented by the Automobile Club committee to the authorities controlling the tolls on Cookham and Goring bridges. The committee are also taking action in respect of the toll at Maidenhead Bridge.

ARRANGEMENTS have been made that there should be an enclosure at Sandown Park racecourse specially reserved for members of the Automobile Club on the day of the Eclipse Stakes Meeting—viz., Friday, 20th, and Saturday, 21st July.

TO the particulars of the Irish motor-car meet already published in our columns we would add that Messrs. Hutton and Company will store a quantity of petroleum spirit at the Lakeside Hotel, Killaloe, and will also send a mechanic to be in attendance on the arrival of the cars.

M. L. DUMONT, of 55, Rue Sedaine, Paris, has recently introduced a new water-circulating pump for petroleum spirit motor-cars. The body of the pump is made of aluminium, thus reducing the weight as much as possible. The pump is arranged to be driven by a strap off the motor shaft or off one of the transmission shafts.

A STEAM carriage of the Stanhope pattern is being introduced by the Oxford Automobile Company, of 53, State-street, Boston, Mass. One of the special claims made for this style of automobile is that the steam is so condensed within the vehicle that none is visible without. The method of starting or firing-up is very simple. The boiler is of the usual tubular form, and is fitted with a regulating device for controlling the supply of petrol to the burner. In addition to the water gauge, there are three gauge cocks so placed as to indicate the amount of water in the boiler. The engine has cranks and rods covered. The storage tanks hold twenty-four gallons of water and five gallons of petrol. The car, when ready for the road, weighs about 950 pounds.

THE BRISSARD WATER-JACKETED COMBUSTION-CHAMBER FOR DE DION MOTORS.

IN our issue of the 23rd ult. we referred to a new water-jacketed combustion-chamber suitable for De Dion motors, which has been put on the market by the London Autocar Company. Curiously enough particulars of another device of the kind have this week been sent us by Messrs. H. Brissard and Fils, of 11, Rue du Colonel-Oudot, Paris. The new water-jacketed combustion-chamber, of which an illustration is given herewith, can, it is stated, quickly be substituted for the ordinary chamber of any air-cooled De Dion motor. The form of the new *culasse* is such that the water-jacket completely surrounds the valve-chamber, thus protecting the latter and also reducing the chance of breakage of the sparking plug, which often takes place owing to excessive heat. The circulation of the water is maintained on the thermo-siphon system, and the installa-

tion can be adapted to a tricycle or a voiturette at a small cost. Messrs. Brissard inform us that their new combustion-chamber has already met with a large adoption in France.

THE Honesdale Automobile Vehicle Company, of Scranton, Pa., has been incorporated with a capital of £20,000.

MESSRS. DE DION, BOUTON AND COMPANY, of Puteaux, have, states *La Locomotion Automobile*, just finished their first electrical car.

L'AUTOMOBILE CLUB DE BELGIQUE is reported to be organising an automobile *caravane* across Belgium on the lines of the 1,000-mile Trial.

THE Chief Constable of Surrey has issued a warning to cyclists and drivers of motor-cars against reckless riding and driving respectively.

Two motor-cars commenced running on Monday last on the route between Downfield and Fairmuir, N.B. The cars are intended to supersede the bus service.

IN order to assure its customers of the best possible value in every respect, the Fadie Manufacturing Company, of Redditch, has effected arrangements with the Motor Manufacturing Company, of Coventry, for the supply of motors of 2½ h.p., made by the latter concern upon the lines followed by Messrs. De Dion, Bouton, but of British workmanship throughout.

CORRESPONDENCE.

THE FIRST PUBLIC SERVICE.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In your last issue there appears a paragraph entitled "Motor-Car Trips," in which you refer to "the Motor Touring Company—the first company, it is said, formed for the purpose of working a passenger service." The claim may be correct as far as mere registration is concerned, but the Blackpool Motor-Car Company, of Blackpool, were undoubtedly running cars for public service long before the Llandudno people had a car on the road. This is proved by a letter sent to one of the journals by, I think, Mr. Aldred, in which he admitted they, unfortunately, could not obtain delivery of the cars they had on order, otherwise they should have had cars running before the Blackpool company. I may be pardoned for referring to so small a matter in that I myself claim to have been the first manager of the first company running public service cars in this country.

7, Liverpool Street, London, W.C. Yours truly,
July 2nd, 1900. A. W. GOODALL.

MOTOR RACING TRACK.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR.—In view of the recent correspondence as to a motor racing track, I went on Saturday to the Crystal Palace to watch the motor-tricycle racing, and came to the conclusion that there is nothing sufficiently attractive about the sport to warrant the scheme suggested. More than that, the limited number of motorists who go in for racing is convincing the public that no fresh men are coming out, and so the same half-dozen riders who raced last season promise to become the mainstay of motor-cycle racing on the track.

It is very clear that there is nothing in motor-car racing either. In France great speeds have practically killed the business, and unless we adopt tricks on motor-cars in connection with competitions I do not see how the public is to be drawn to see automobile competitions. The public is interested in observing various types of cars travelling at reasonable rates of speed, but motor racing is as uninteresting as bicycle racing has become.

Yours truly,
Penge, S.E., July 3rd, 1900. A NOVICE.

A GERMAN DAIMLER RACING CAR.

THE illustration on the opposite page shows one of the racing cars built by the Daimler-Motoren Gesellschaft, of Cannstatt, Germany, for the recent automobile season at Nice. The vehicle, which has accommodation for four persons, is provided with a four-cylinder Daimler motor, capable of developing up to 28 h.p. Four speeds forward and reverse motion are available, the transmission of the power to the rear axle being on the well-known Daimler system. Special attention has been paid to the water-cooling and braking arrangements. The car, which is fitted with wooden wheels shod with stout pneumatic tires and inclined wheel steering, is stated to be capable of attaining a speed of from fifty to sixty miles per hour on the level. We are indebted to the *Motorwagen* for the illustration.

TEN entries have, we understand, been received for the English Motor Club's hill-climbing competition at Tilburstowe, near Godstone, at four o'clock this (Saturday) afternoon. The contest will be held under the rules of the Competition Committee of the A.C.G.B.I. as a class B competition.

M. P. FAGEOT AINÉ, of Neuilly, near Paris, has sent us a copy of his latest catalogue of motors, voiturettes, and motor-car and cycle accessories and parts of every kind. Prominence is given to the Fageot vertical petrol motor, which is made in sizes from $2\frac{1}{2}$ to 5 h.p. The list is most complete, and should be in the hands of all interested in the motor trade.

THE AUTOMOBILE CLUB'S 100-MILE TRIAL.

THE quarterly 100-mile Trial of the A.C.G.B.I. was held on Wednesday, the 27th ult., when three competitors presented themselves. The Automobile Association kindly placed their premises at the disposal of the club, and Mr. Wyatt and Mr. Buttemer assisted as observers. The usual route was followed, viz., from the second milestone from the Marble Arch, *via* Ealing, Uxbridge, Beaconsfield, High Wycombe, and Stokenchurch to the fifty-second milestone (outskirts of Oxford) and back. Total 100 miles. The condition of the roads was fair, although dusty at places and loose on Dashwood Hill. The weather was fine. Wind light from the westward. The hills on which hill-climbing trials took place were:—(a) Dashwood Hill, commencing at the thirty-third milestone and terminating at the thirty-fourth milestone, having a total rise of 241ft. in 1 mile, including 275yds. of a gradient of 1 in 21.7, and 600yds. of a gradient of 1 in 11. (b) Aston Hill, on the return journey. Distance 1 mile 1,100yds., having a total rise of 386ft. and including 1,910 yds. of a gradient of 1 in 21. The following are the records of the three vehicles which competed:—

The Motor Manufacturing Company's Motor-Tricycle.—Motor: $2\frac{3}{4}$ h.p., 79 m.m. cylinder, with 85 m.m. stroke. Quantity of petroleum spirit used on the journey: 1 gallon 3 pints. Speed up to the legal limit of twelve miles per hour. Number and cause of stoppages: (1) At the end of fifty miles, stopped $10\frac{3}{4}$ min. to fill carburettor, the pipe leading from spirit reservoir to carburettor having become unscrewed and lost. (2) At end of sixty-third mile, stopped 6 min. 10 sec. for same reason and purpose. (3) Stopped at ninety-fifth mile to obtain a lamp, "lighting up time" having arrived. Hill-climbing speeds: (a) Dashwood Hill: 14.40 m.p.h., without pedalling. (b) Aston Hill: 13.9 m.p.h., without pedalling. General remarks: The observer states that no pedalling came under his notice, except for starting purposes.

The Motor Manufacturing Company's Iveagh Phaeton.—Motor: two cylinders of 90 m.m. with 120 m.m. stroke. Quantity of petroleum spirit used on the journey: $4\frac{1}{2}$ gallons. Quantity of water used on the journey: 2 gallons. Speed up to the legal limit of 12 miles per hour. Number and cause of stoppages: (1) during fifteenth mile pressure was lost in spirit tank; stop of eight minutes in finding cause. Hill-climbing speeds: (a) Dashwood Hill, 6.42 miles per hour; (b) Aston Hill, 6.68 miles per hour. General remarks: Except for the one stop above recorded, the vehicle ran steadily and well, especially on the return journey.

The Motor Carriage Supply Company's Simms Motor-Wheel.—To carry two passengers, $2\frac{3}{4}$ b.h.p. motor, one cylinder $2\frac{3}{4}$ in., with $3\frac{1}{4}$ in. stroke. Quantity of petroleum spirit used on the journey: 1 gallon $7\frac{1}{4}$ pints. Speed up to the legal limit of 12 miles per hour. Number and cause of stoppages: (1) On Dashwood Hill, where passenger alighted and walked to the top; (2) at 56 miles, stopped 2 minutes for restless horse; (3) at 62 miles, stopped 13 minutes to replenish petroleum spirit tank and lubricator. Hill-climbing speeds: (a) Dashwood Hill, 6.66 miles per hour, passenger alighted; (b) Aston Hill, 9.75 miles per hour, pedals not used. General remarks: At fifty-second mile, right-hand stay of mudguard broke; at fifty-third mile, left-hand stay of mudguard broke. The vehicle ran steadily and satisfactorily. It was in passing another vehicle by which the Simms' motor-wheel was forced on to the loose portion of the road on Dashwood Hill that the stoppage occurred which necessitated the passenger alighting.

THE Police Board of Hartford, Conn., U.S.A., has been asked to appropriate the sum of £800 for a motor patrol wagon.

THERE are on view at the Automobile Club the handsome challenge cups, which have been presented in connection with the motor-cycle meeting held at the Crystal Palace on the 30th ult.

A MOTOR-CAR tour in Algeria is projected by *La France Automobile*. The distance would be 900 kilomètres, and February next is the date proposed for the tour.

PARIS EXHIBITION NOTES.

(FROM OUR OWN CORRESPONDENT.)

I SUPPOSE that there is any number of people in England whose original intention it was to visit the Paris Exhibition not later than the end of last month, and who subsequently decided, consequent upon the reports as to the unfinished condition of the big show, to postpone their visit until towards the close of the summer. The premature opening of the Exhibition has proved to be unfortunate from every point of view, for the early visitors went away firmly convinced that the installation of many of the sections could not possibly be completed in less than three months, and advised their friends accordingly. The result to-day is that the number of foreigners and provincials visiting the show has by no means come up to expectations, and that the predominating element in the crowd is Parisian. But there is really no need now to postpone one's visit: indeed, to my mind, it would be better to make it at once. Certainly the Annexe at Vincennes is not anything like complete, nor will it be for some time to come, but the motor-man can already see an enormous variety of vehicles there, and the automobile class in the Exhibition proper is entirely installed. Come at once then, I say, for shortly we shall be entering upon that spell of trying heat which renders Paris almost unbearable during July and August, while later on there is sure to be a great influx of visitors anxious to view the last of the Exhibition, and the corresponding annoyance in the matter of accommodation, etc., will be experienced. Of course Paris is crowded now—

greatly crowded; and one should certainly engage rooms before coming over, as otherwise a long and trying search would probably result, but I think that in September the difficulty of securing accommodation will be even greater. If you intend to see the Exhibition, then, visit it now, for it is ready; and as you may not be quite certain as to its whereabouts I will endeavour to tell you exactly where one must look for

CLASS 30 AT THE CHAMP DE MARS.

Broadly speaking, the Exhibition proper is divided into three great sections, viz., Esplanade des Invalides, Trocadero, and Champ de Mars, the last-named being the furthest from the grand boulevards. At Champ de Mars, in Group VI., the group reserved for civil engineering and means of transport exhibits, there is to be found the automobile section, the number of the class being 30. Group VI., Class 30, at Champ de Mars, then, is the exact address at which the motor-man will find examples of some of the newest types of automobiles, and I will now endeavour to lead him there by the best and quickest routes. If a cab be taken, the driver should be told to go to the entrance in the Avenue de Suffren. There are several entrances to the Exhi-

bition in the avenue, but none of them are very far from the automobile class, and the nearest to it is the one about half-way down. No money is taken at any of the Exhibition gates, admittance being by ticket only. These tickets are on sale all over Paris, and vary in price from 45c. to 75c. each, according to the market quotation. Usually there are a dozen vendors hanging round every entrance, but it is a good plan to buy at one time as many as you are likely to require, and so be independent. The number of tickets given up at the entrance depends upon the day, but generally speaking one ticket only is required when entering between ten o'clock in the morning and six at night. To reach the Exhibition by train, one should travel from the Gare St. Lazare to the Gare du Champ de Mars. Upon alighting at the latter station one has but to cross the Avenue de Suffren and enter by the gate almost in front of the station. If the river be preferred—and to my mind it is the most delightful if not the quickest means of transport—one can go on board at any of the piers, bearing in mind that the boats never cross the river, but always keep to one side. The side upon which the Opéra, etc., is found is known as the *rive droite*, the other side the *rive gauche*. Leave the

boat at the Pont d'Iéna, where one enters direct into the Exhibition. It is better to be provided with entrance tickets, as one may not be able to procure them on the boat, and there are no vendors on the piers. Should you wish to take an omnibus or a tram you are more likely to find a seat on those going to the Trocadero than those to Champ de Mars, and it is not far to walk from the former place to the automobile section. The big green tramcar leaving the Madeleine for Auteuil by way of the Boulevard

A 28-H.P. GERMAN DAIMLER RACING CAR. (See opposite page.)

Hausmann will take you to the Trocadero, and there is also an omnibus which passes by the Gare St. Lazare and labelled "Gare de l'Est—Trocadero." The omnibuses which go direct to Champ de Mars are the Gare St. Lazare—Javel and the Porte St. Martin—Grenelle, but unless you go to the starting point it is always difficult to secure a place. Once in the Champ de Mars section, and facing the wonderful fountains known as the Château d'Eau—that is, with one's back to the Trocadero—one finds the automobile class on the right. The entrance to it is about half way down the long building which reaches from the one foot of the Tour Eiffel to the Château d'Eau, and the imposing gateway bears, among other titles, "Génie Civil, Transports, Travaux Publics." Enter there, and to right and to left one finds automobiles galore, while erected against the walls of this splendid hall are cases containing a great variety of accessories necessary to the existence of a motor.

And now, having safely placed you there, O man of motors, I would say commence with the exhibition of the Musée Centennial des Voyages et du Tourisme, for after an inspection of the

exhibits there you will be in a fit frame of mind to appreciate the progress made during the last fifteen years. This small collection of antiquities is found on the left of the passage which runs direct from the entrance into the body of the hall. Consisting for the most part of cycles of the bone-shaker and hobby-horse types, it includes, however, three very interesting automobiles. First of all there is an enormous steam diligence, built by M. Amedée Bollée in 1885 for the Marquis of Broc, of the Château des Perrais, at Parigné le Pôlin, in the Sarthe district. It is of truly huge proportions, and appears to bear its fifteen years of existence with ease and contentedness. Then there is the first petrol motor-cycle manufactured by MM. De Dion and Bouton, and, screened by the giant diligence, there is a weird collection of boilers, taps, and cocks, the whole mounted upon three wheels, and bearing an inscription to the effect that it is the initial effort of the same Puteaux firm to produce a steam motor-tricycle.

Turn from that and its petrol relative and have a look at the stand of MM. De Dion and Bouton, which is upon the same side of the central passage, but nearer to the door by which we entered, and then you can see what a few years have done for automobilism. Look at those beautiful "quads" with grace and strength shown in every line, and compare them with what has gone before. It seems almost incredible in such a short space of time. On this stand, too, are to be seen samples of the firm's well-known voiturette, while conspicuously placed in the centre is a snowy white frame, the motor and gear of which daily attracts considerable attention.

The modern productions of the other exhibitor in the retrospective section, viz., M. Amedée Bollée, are just on the other side of the gangway, and consist of five cars built by MM. Dietrich and Co. on his system. Certainly the Lunéville firm has not a very great annual production, perhaps a hundred or so vehicles, but all the same it is a matter of astonishment to me that the type is practically, if not entirely, unknown in England. One of the handsomest cars in France, it is also one of the most reliable; indeed, you will find many authorities who regard it as equal to any vehicle produced this side of the Channel. If some of the English firms trading between the two countries would take some measures to exploit the car in England good business ought certainly to result.

A stand which is very conspicuous in the immediate neighbourhood is that of the Société des Chaudières et Moteurs Scotte, for there one sees three giants of the automobile world. Two mighty Scotte trains, each fitted with a thirty horse-power engine, and a third provided with a ten horse-power, go to make up this interesting collection. The prices of the larger trains are about £1,100, and the firm have a new twenty horse-power type in course of construction. In dozens of places these tractors are doing excellent work, and I may cite the services in the Ardèche, in the Saône-et-Loire, in the Ain, Isère and Drôme, at Bougie and Sétif, at Buxy, Roubaix and Tourcoing, etc. Not the least noteworthy feat achieved by a Scotte train was performed this spring, when the railway carriage exposed by the Compagnie Internationale des Wagon-Lits in the Russian section of the exhibition, and actually intended for use on the Trans-siberian Railway, was towed by a Scotte tractor from Saint Denis to Paris in three hours. This railway car brings down the scale at 35,000 kilogrammes, no light weight to tow up what in places are grades of 8 per cent.

Just in front of the Scotte exhibits a well-known name catches the eye. It is the name of Otto, and the productions exposed are a couple of vehicles built by the new company in the huge works of the parent concern, where for so many years the "Otto" gas engines have been constructed. One naturally takes a keen interest in anything emanating from this company, for was not Gottlieb Daimler a collaborator of Otto, whose system is now represented in Europe by some 50,000 gas engines? The cars exposed are unfortunately not finished, and as they lack in several interesting details it is only possible to give a general description of them. Built on Panhard lines, the motor is carried in front in a very similar bonnet; indeed, the whole car resembles very closely in appearance the productions of the Ivry firm. The motor is of the two-cylinder vertical type. It is provided with electric ignition, and a Longuemare carburator is used. The

smaller of the two cars shown is fitted with three speeds and reverse, and the larger vehicle four speeds and reverse. The motors develop 6 h.p. and 10 h.p. respectively. The usual pedal and hand brakes are attached—the former acting on the differential shaft, while the latter operates upon the sprocket wheels. The application of either of these brakes also throws the engine out of gear. Altogether the car has a smart and attractive appearance, and the long experience of its constructors should be an excellent guarantee of its construction and of its effectiveness.

(To be continued.)

MOTOR RACING AND CLIMBING.

AT THE CRYSTAL PALACE.

SATURDAY was a dull day at the Crystal Palace. The weather frowned unkindly, and from the terrace of the great glasshouse a mist was seen enveloping the grounds that are ordinarily so beautiful and attractive. It saddened those who had entered for the motor-cycle races on the track, and it—or something else—kept the spectators away. Certainly the cars that went on the 1,000-mile Trial could have carried all the on-lookers as passengers and left not a score behind. At one time about a hundred of the public lined an elevation overlooking the track, but a sharp shower drove them away to return no more that afternoon. About half a dozen motor-cars brought sightseers, and a few members of the Automobile Club were seated on the grand stand, while others stood in the enclosure; but evidently touring is more appreciated than racing, and the attraction of ten entrants for four contests was not great.

However, those who were there passed the time pleasantly enough. There was good sport in the first half hour of the racing, as Messrs. Jarrott and Machin kept together with wonderful tenacity, alternately leading by a few lengths; and there was good company in the members present. But when tire troubles began the interest of spectators obviously slackened. Mr. R. E. Phillips was the judge and Mr. T. W. Staplee Firth was the starter, while Mr. C. Johnson appeared in the capacity of competitors' steward, Mr. H. J. Swindley being official time-keeper.

The first event was a one hour scratch race for the *Autocar* challenge cup, but of the six who had entered, only Messrs. F. Wellington (unfortunately suffering from rheumatism in the right arm and riding against the doctor's orders), C. Machin, C. Jarrott, and E. Buck turned out for the race. For the first four laps the order of going was Jarrott, Machin, Wellington and Buck, and then the positions of the two leaders were reversed for a lap or two, when Jarrott again led. An interesting competition for third place was going on between Buck and Wellington, which continued until the former's retirement a few laps later, something going wrong with the machine. Wellington then went steadily along, and Jarrott and Machin fought hard for the first place, there being never more than eight lengths between during the first half-hour, when twenty miles had been covered. Unfortunately in the next mile Jarrott's tire was punctured, and the race was virtually over. Within ten minutes he was again on the track, but left ere the hour was up, and the result was as follows:—C. Machin, 1; F. F. Wellington, 2; C. Jarrott, 3. The former, riding a 7 h.p. Aster, covered 39 m. 234 yds., as against M. Rigal's record of 38 m. 1,372 yds. on the same track on Whit-Monday. Towards the end of the race his tire showed signs of wear, and but for that he might have reached the forty miles. Anyhow, Machin's was an extremely good performance. Wellington, who rode a 7 h.p. Phœbus Aster, was heavily handicapped in that, as in subsequent races, by his rheumatism. Jarrott's machine was a 5 h.p. De Dion.

In the five-mile scratch race for motor touring cycles, for the *Motor-Car Journal's* challenge cup, the six entries were reduced to three starters—Messrs. Wellington, Buck, and A. E. J. Steele. This proved a win for Steele (Simpson and Strickland tricycle), Wellington (2½ h.p. Phœbus) and Buck (Motor Manufacturing Co.'s tricycle with Soncin motor) being placed second and third respectively. The winner's time was 11 min. 2 2-5 sec., and he won by over a lap.

Owing to the absence of the competitors the three miles Club motor-cycle handicap, which was to have concluded the meeting, was not run, and the ten mile handicap for the *Auto-motor* challenge cup brought the racing to an end. Here again Jarrott had bad luck, his machine breaking down after he had led a considerable distance and had lapped Steele. The result was as follows:—E. Buck, 5 laps start (3 laps to the mile), 1; A. E. J. Steele, 9 laps, 2; F. F. Wellington, 2 laps, 3; C. Machin, scratch, 0; C. Jarrott, scratch, 0. Buck's time was 14 min. 2-5 sec., and Machin's time 14 min. 55-1-5 sec.

Half a dozen cars were in the grounds of the Palace. Mr. C. Johnson had his Daimler, Mr. Burgess was on a Motor Manufacturing Company's vehicle, Mr. W. J. Peall had come on his Daimler, Captain Langrishe was on his car, and Mr. Cordingley on his Marlborough phaeton. The racing over, a start was made for Westerham, the nasty incline leading from the Palace grounds necessitating the lightening of some of the cars. A short distance from the Palace we (on Mr. Cordingley's car) passed Mrs Kennard on her Benz, and then a good run was enjoyed to Bromley, where tea was hastily partaken, and across Hayes Common we enjoyed a lovely prospect. This route was a couple of miles longer than by the main road to the left of the railway station, but the prettiness of the view was worth the detour. Right across the common was a wealth and profusion of ferns such as is not often seen so near London. Half way across Messrs. Edge and Napier on the 16 h.p. Napier car dashed by, their onward track being clouded in dust. In some of the lanes beyond parties of bean-feasters were met, and the usual ejaculations were heard; otherwise the ride was delightful. The evening was cool, not cold; and some of the lanes through which we rode not unlike those leafy, grass-grown walks of Devonshire which give that county its joy and pleasure. Tall were the hedges and fragrant the smell of the hay that came with every freshening breeze, while here and there between graceful beeches we saw fields of wild flowers—and only an hour's journey from town. Thence to Westerham the way was uniformly delightful, a cheering ending to a dull afternoon.

AT WESTERHAM.

Here a hill-climbing competition for automobiles had been arranged by the Catford Cycling Club, under the A.C.G.B.I. rules, with Mr. Robert Todd as judge and Mr. Alex. Slimon as secretary.

At the top of the hill were several cars that did not venture down. Mr. C. Johnson and Mr. Worby Beaumont walked along looking for the steepest gradient, and forgetful of the car the former had entered. Mr. T. B. Browne's party were on his Panhard. A Richard car was there, affording an opportunity for a reminiscence of the 1,000-mile Trial. Mr. Weguelin's Panhard racing machine—once belonging to a leading French *chauffeur*—was, we heard, at the foot of the hill, whither the Napier car had gone to the wonderment of a few natives in the crowd of cyclists and motorists. To enumerate all who were present would be impossible, as the hill was long and the motorists stragglers as they footed up and down watching with interest the struggles of vehicles to the summit. But it was a fairly representative company, and some local owners of cars had appeared to give volume to the scene. The *Daily News* of that morning had had something to say about motor-men's garments. We wish the writer could have seen one gentleman on his car with his top-hatted groom demurely sitting beside him, looking for all the world as though he had lost the pony. Very sedate, very lonely he looked.

Down to the bottom of the hill we trudged, determined to see all that could be seen. A returning party of motorists warned us that the way was long and the return was steep. We waited awhile until a welcome "teuf, teuf" announced that something was coming. It was a motor-tricycle, the rider looking pale and determined. He had no number, and so his identity must remain obscured. Then Mr. Harvey Du Cros, jun., whizzed by. Later he returned to enjoy another trip to the hill top. Then was the noise of the first car heard in the stillness of the evening—for it was growing late—and with a plodding, persevering persistency Mr. F. Wellington's 6-h.p. Daimler car hove in sight with Mr. Swindley aboard. They turned the bend slowly, and slowly they finished the ride at a pace which occasioned no alarm and would have

disturbed no policeman, had such an official been present. Mr. Edge and Mr. Napier came up in good style, but not far from the summit left the beaten path, and striking a hedge decided to go no further, one of the brakes giving way. The car was reversed, and went down the hill more slowly than it ascended, and we saw it no more. Then ten minutes of patient watching until Mr. C. Jarrott hove in sight, closely followed by No. 25, both pedalling hard. The performances of the motor-cyclists came into prominence at this point. No. 28 went up and 25 came down again, followed by 28 a few minutes later. Then 27 pedalled upwards and 32 and 26 returned to the bottom—whether for the fun of another effort or to beat the record we could not say, and did not trouble the riders to inquire. They were all intent about their business.

After the motor-tricycles the coming of a car was interesting as a relief to the monotony. It proved to be Mr. Weguelin's Panhard, and went up well. A few minutes later it came down the hill splendidly under control. Then came V. Lee on Mr. Edge's Ariel tricycle in the smartest time of the day—an exceedingly good performance; and the last we saw of the trials was Mr. T. B. Browne's Panhard, having been relieved of passengers, being coaxed from the rear. Strong shoulders and willing hands helped it to reach the top. The whole course up the hill was a mile in length, and the times of those who made the ascent are given below.

		Mins.	Secs.
32. V. Lee...	Ariel tricycle	2	58 $\frac{1}{2}$
25. F. F. Wellington's representative	do.	3	7 $\frac{3}{4}$
27. B. Hopps	do.	3	28
26. Harvey Du Cros, jun.	do.	3	29 $\frac{1}{2}$
28. Roger H. Fuller	Tricycle	3	38 $\frac{1}{2}$
38. H. Weguelin	12 h.p. Panhard	3	49 $\frac{1}{2}$
30. Chas. Jarrott	Ariel tricycle	4	32 $\frac{3}{4}$
36. F. F. Wellington's representative	Daimler car	11	45

At half-past eight we turned our car about and started for home. There was still a breeze, which was as pleasant as ever, and having shaken off a few cyclists, who would keep at a dangerous proximity, we travelled the high road, keeping off the common we had crossed earlier in the day, and observing a small triangular cemetery in pleasant seclusion and delightful location. Clean, businesslike Bromley, that had appeared so cheerful on the outward journey, was now full of people marketing and waiting in its streets, and then a long stretch of open country separated us from purely London suburbs. We had a taste of the dust shortly after leaving Bromley, Mr. Weguelin's car kicking its heels violently as it rushed by and giving us a cloud that could be felt and tasted, but not appreciated. We had appetites, for the fast had been long; but suburban dust is not satisfying. Nor is the odour of the establishments for purveying the flesh of sea fishes to Londoners any more appetising. Of that we had plenty as, through Deptford and New Cross, we went into the Old Kent Road on the way to Westminster. Big Ben was pointing ten minutes to ten o'clock as we crossed the Thames, beyond which our route lay through familiar paths.

The conclusion of the whole matter is that motor-tricycle racing is all very well, and that motor hill-climbing is rather better, but that motoring across the country for purposes of enjoyment only is the preferable pastime of the three.

AN ordinance has been passed in Newport, R.I., U.S.A., restricting the speed of motor-vehicles in that city to six miles an hour in the business section and ten miles an hour in the outer portions.

THE Daimler Motoren Gesellschaft, of Cannstatt, Germany, have sent us a number of separate circulars illustrating and describing their latest types of motor-vehicles, including delivery van, omnibuses, etc.

PROFESSOR R. W. WOOD and Mr. Joseph Jastrow, of the University of Wisconsin, rode in a Locomobile car from Milwaukee to Madison, Wis., on the 8th ult., covering the eighty-five miles in 5 $\frac{1}{2}$ hours. So far as known this is the first long-distance trip made in Wisconsin.

THE 1,000-MILE TRIAL.

—8—

THE REPORT AND AWARDS OF THE JUDGES' COMMITTEE.

THE Judges' Committee, in arriving at their decisions, have allotted marks under the following amongst other headings:—Price; weight; horse-power, shown by performance; persons carried; price in proportion to seating capacity occupied; price in proportion to power of motor; power in proportion to seats occupied; power in proportion to weight; mechanical efficiency as shown by hill-climbing trials; simplicity of transmission; accessibility of mechanism; quality and sufficiency of speed gear; easiness of adjustment; steering gear; brakes and brake gear; ignition arrangements and apparatus; general design, mechanically; general design, appearance; average speed on Trial out of control in proportion to average of legal limit; workmanship, especially of machinery; condition of car at end of trial; regularity of running on Trial; breakages and defects not previously mentioned; general observance of Trial regulations.

ENTRIES.—Eighty-three vehicles in the various classes were entered for the Trial, but some of these were not completed, or from other causes did not appear at the time of the start on the morning of the 23rd of April. Sixty-five started, and, with the exception of a few vehicles, most of which ought never to have started, all covered the whole or greater part of the course. The analysis and the tables* given in the appendix to the report show the performance of all the vehicles which returned to London and were exhibited at the Crystal Palace.

All the vehicles were examined at the Agricultural Hall on Saturday and Sunday, the 21st and 22nd of April, by some of the judges, and stamped for identification in several places.

On their return to London, those of the vehicles which completed the whole tour were exhibited at the Crystal Palace, where they were re-examined for identification, and records were taken of the condition of the gear and other working parts.

The judges do not propose to enter into any detailed criticism of the performance, structure, and condition of the vehicles before and after the Trial, as all these questions have been separately considered with respect to every car, and numerical value given to each in making the awards under the above headings, but they wish to draw attention to the extremely satisfactory progress which has been, and is being, made in the construction not only of the carriages generally, but in the arrangement, accessibility, and workmanship, particularly in this country, of the transmission and other gear of many of them. Marked improvement has also to be noted in the carriage-builders' work of several automobiles, the carriage builders having realised the possibility of and necessity for lightness of construction, combined with comfort and elegance. Aluminium has been used successfully in making the bodies, and the same metal has been largely employed in the fixed parts of the machinery.

The reduction in weight which has been thus effected by some British manufacturers has had a marked effect upon the hill-climbing powers and efficiency of the cars as a whole.

SPEED IN CONTROLS.—The rules for the 1,000-mile Trial specially provided that a competitor should not drive his vehicle at a speed exceeding eight miles an hour through towns and villages, which were specially indicated in the official programme, and by flags exhibited by timekeepers on the road side. An examination of the time-sheets shows that, while some competitors have adhered scrupulously to the rules, and others have evidently adhered to the spirit of the rule by moderating their speed, but not sufficiently when passing through controls, on the other hand certain competitors have almost entirely disregarded the rules which were made to prevent the possibility of accidents or annoyance to the inhabitants of towns and villages situated on the route of the Trial.

The Judges' Committee, in order to mark their appreciation of the conduct of drivers who showed self-command and respect

for the rules by proceeding at a very slow speed through controls, have, in making their awards, allotted marks in accordance with the behaviour within controls of the driver of each vehicle.

The following drivers are to be commended for their adherence to the rule as to speed within controls. The highest possible number of marks was 100.

The Hon. C. S. Rolls (No. A17)	93.22
The driver of the New Orleans Car (No. 28)	76.08
" " " " Brown-Whitney car (No. 23)	74.64
" " " " Mr. Mayhew's Peugeot (No. A29)	72.88
" " " " Cordingley's car (No. A23)	72.76
" " " " the Benz Ideal (No. 2)	69.78
Mr. Edge, who drove Mr. Kennard's car (No. A10)	69.41
The driver of the Marshall Carriage (No. 24)	69.41

The Judges' Committee recommend that if any road trial of a similar nature be organised by the club, competitors should be warned that failure to observe strictly the rule as to speed within controls will undoubtedly involve disqualification, and, further, that disqualification should ensue from a practice, which was only too common during the recent Trial, and which tended to make the Trial a nuisance to other users of the road, viz., the breaking of single file and crowding of vehicles across the whole width of the road while awaiting despatch from the outward control, or awaiting registration at an inward control.

CAUSES OF FAILURE.—The Judges' Committee wish to place on record that enquiries tend to show that most of the failures of vehicles to obtain good records on various stages were due, not to the failure of motor or of the transmission gear, but to structural weaknesses in other parts of the carriage. For example, breakage of axles took place in three instances, and the puncture of pneumatic tires was especially responsible for delays. It is well, then, that the general public, when forming an impression of the Trial, should bear in mind that a large proportion of the delays cannot properly be put down to what are usually known as "breaks down" of the motor.

The Judges' Committee trust that manufacturers of wheels, springs, axles, and tires will specially turn their attention to the manufacture of parts of suitable material, design, and proportion, for use in the construction of motor vehicles.

PUBLIC SERVICE VEHICLES.—Special prizes were offered for public service vehicles, it being evident that there is, and is likely to be, a considerable demand for this class of vehicle; and that the transmission gear used in the ordinary light, privately-owned vehicle is not suitable for use in cars constructed to carry large numbers of passengers.

The Daimler Company entered a vehicle (No. 38) specially designed for public service, which being the first of its sort, may be looked upon as experimental, and, as such, gives promise of this company being able to provide shortly a thoroughly sound and suitable vehicle for the conveyance of at least a dozen passengers.

THE CLIPPER TIRE.—The Judges' Committee wish to notice the earnest attention which the Clipper Tire Company is giving to the manufacture, in this country, of pneumatic tires suitable for use on automobiles. This Company submitted to trial a set of pneumatic tires, and these tires were under the observation, during the 1,000-mile Trial, of official observers acting on behalf of the club. This set of tires did not wear well during the Trial, but other tires manufactured by the same company were fitted to vehicles which went throughout the Trial, and were in fair condition at the conclusion of it.

AWARDS.—The recommendation of the Judges' Committee as to awards and an analysis of the running of the various vehicles entered for the Trial are appended hereto:—(Signed) Archibald Barr, Hudson Beare, W. Worby Beaumont, C. Vernon Boys, D. S. Capper, Dugald Clerk, Bryan Donkin, H. S. Hele-Shaw, H. C. L. Holden, Wm. H. Preece, Boverton Redwood, David Salomons, Bart., James Swinburne, Wm. C. Unwin, A. F. Yarrow, Judges' Committee.

Sir David Salomons signs and approves the Report and awards subject to dissent from placing the Locomobile carriage for a prize, on the grounds that at the present time the "Locomobile" produces visible steam, contrary to the 1896

* These were published in our issue of 16th June.—[Ed. M. C. J.]

Locomotives on Highways Act. Also the boiler interior is virtually inaccessible; consequently, until these defects are remedied, the carriage should receive no mark of commendation whatever.

AWARDS.

The Judges' Committee recommend to the Club Committee that the following prizes should be awarded in connection with the 1,000-mile Trial of 1900:—

SECTION I.

(Vehicles entered by Manufacturers or Agents.)

Class A. (Vehicles declared at a selling price of £200 or less).—First prize (10 per cent. of prize fund), No. 2, Benz Ideal; second prize (each 5 per cent. of prize fund), No. 5, Locomobile steam car; No. 27, New Orleans voiturette.

Class B. (Vehicles declared at a selling price of more than £200, but not more than £300).—First prize (10 per cent. of prize fund), No. 40, Wolseley voiturette; second prize (5 per cent. of prize fund), No. 31, Motor Car Company's Triumph; third prize (3 per cent. of prize fund), No. 15, De Dion voiturette.

Class C. (Vehicles declared at a selling price of more than £300, but not more than £500).—First prize (10 per cent. of prize fund), No. 35, Daimler Company's car; No. 36, Daimler Company's car; No. 37, Daimler Company's car. Second prize (5 per cent. of prize fund), No. 9, Motor Manufacturing Company's car; No. 8, Motor Manufacturing Company's car.

Class D. (Vehicles declared at a selling price of more than £500).—No awards.

Class E (a) (Motor-cycles carrying one person only).—No awards.

Class E (b) (Motor-cycles carrying two persons).—First prize (10 per cent. of prize fund), No. 3, Ariel quadricycle; second prize (each 5 per cent. of prize fund), No. 4, Ariel tricycle with Whippet trailer; No. 39, Century Tandem.

Class F (Public service vehicles).—No award.

27 per cent. of the prize fund is reserved for Section II.

It is recommended that the *Daily Mail* prize of £10 for every vehicle successfully completing the Trial in Section I. should be awarded in respect of the following vehicles:—

Class A.—No. 1, Benz Ideal; No. 2, Benz Ideal; No. 16, Gladiator voiturette; No. 27, New Orleans voiturette; No. 34, Decauville voiturette; No. 41, International Victoria; No. 44, International Victoria.

Class B.—No. 15, De Dion voiturette; No. 40, Wolseley voiturette; No. 49, Marshall carriage.

Class C.—No. 8, Motor Manufacturing Company's 6 h.p. phaeton; No. 9, Motor Manufacturing Company's Iveagh phaeton; No. 26, Friswell, Limited, 8 h.p. Peugeot; No. 35, Daimler Company's 6 h.p. car; No. 36, Daimler Company's 6 h.p. car; No. 37, Daimler Company's 6 h.p. Parisian; No. 46, Richard car; No. 47, Richard car.

Class D.

Class E. (b).—No. 3, Ariel quadricycle; No. 4, Ariel tricycle with Whippet trailer.

The judges have made several recommendations to the proprietors as to the award of the *Daily Mail* prize to vehicles in respect of which records are not absolutely complete.

SECTION II.

(Privately-owned Vehicles.)

It is recommended that:—

The Gold Medal for the vehicle which, in the opinion of the judges, is the most meritorious irrespective of class (the owner having accompanied the vehicle throughout, and having driven and steered at least half the distance), should be awarded in respect of vehicle No. A17, a 12 h.p. Panhard car, owned by the Hon. C. S. Rolls.

The Silver Medal for vehicles which have successfully accomplished the trial (the owners having accompanied their vehicles throughout, and driven and steered at least half the distance) should be awarded in respect of the following vehicles:—

Class A.—No. A25, Mrs. Bazalgette's Benz Ideal.

Class B.—No. A24, Mr. Robert Phillips's Mors voiturette.

Class C.—No. A2, Mr. Frank H. Butler's 6 h.p. Panhard; No. A3, Mr. T. B. Browne's 6 h.p. Panhard; No. A21, Mr. Ernest Pitman's 6 h.p. Daimler; No. A26, Mr. C. K. Gregson's 6 h.p. Daimler; No. A30, Mr. J. D. Siddeley's 6 h.p. Daimler; No. A31, Mr. Wm. Exe's 6 h.p. Daimler.

Class D.—No. A22, Mr. J. A. Holder's 12 h.p. Daimler; No. A28, Mr. E. M. Iliffe's Enfield quadricycle.

Bronze medals for vehicles which successfully accomplished the Trial, and in respect of which neither a gold nor silver medal has been awarded, should be given in respect of the following vehicles:—

Class C.—No. A7, Mr. Alfred Harmsworth's 6 h.p. Daimler, driven throughout by Captain H. R. Langrishe; No. A10, Mr. Edward Kennard's 8 h.p. Napier, driven throughout by Mr. S. F. Edge; No. A12, Mr. H. Edmund's 6 h.p. Daimler.

Class D.—No. A11, The Hon. John Scott Montagu's 12 h.p. Daimler.

The Judges' Committee have decided that the following are the first and second in order of merit in their classes in Section II.:—

Class A (vehicles declared at a selling price of £200 or less).—No award.

Class B (vehicles declared at a selling price of more than £200, and not more than £300).—First, No. A24, Mr. Robert Phillips's Mors voiturette.

Class C (vehicles declared at a selling price of more than £300, but not more than £500).—First, No. A10, Mr. Kennard's 8 h.p. Napier; second, No. A30, Mr. Siddeley's 6 h.p. Daimler, and No. A3, Mr. T. B. Browne's 6 h.p. Panhard. Mr. W. Exe's car (No. A31) was withdrawn from competition for a place.

Class D (vehicles declared at a selling price of more than £500).—First, No. A17, The Hon. C. S. Rolls' 12 h.p. Panhard; second, No. A22, Mr. Holder's 12 h.p. Daimler.

Class E (a) (motor-cycles carrying one person only).—First, no award; second, No. A20, Mr. Ashby's Empress motor-tricycle.

Class E (b) (motor-cycles carrying two persons).—First, No. A28, Mr. Iliffe's Enfield quadricycle; second, no award.

SECTIONS I. AND II.

Medals of the Automobile Club de France.

The Judges' Committee recommend that the medals given by the Automobile Club de France be awarded for the three vehicles which in their opinion are, irrespective of section or class, the second, third, and fourth in merit, viz.:—First, silver-gilt medal, Mr. Kennard's 8 h.p. Napier (No. A10); second, silver medal, Wolseley voiturette (No. 40); third, bronze medal, New Orleans voiturette (No. 27).

SECTION II.

Mr. Owers' Cup.

The judges award the silver cup, presented by Mr. Ernest Owers, for the best vehicle in Section II. to the Hon. C. S. Rolls' 12 h.p. Panhard.

ANALYSIS OF PERFORMANCES.

Analysis of performances of the vehicles entered for the Trial:—

A. The following vehicles completed the entire Trial, having maintained a speed of not less than the legal limit (*i.e.*, 12 miles an hour in England and 10 miles per hour in Scotland) throughout, viz.:—

Section I. Class A.—No. 16, Gladiator voiturette; Class B.—No. 15, De Dion voiturette; No. 40, Wolseley voiturette; Class C.—No. 9, Motor Manufacturing Company's Iveagh phaeton; No. 35, 6 h.p. Daimler; Class E (b).—No. 3, Ariel quadricycle; No. 4, Ariel tricycle, with Whippet trailer.

Section II. Class C.—No. A3, 6 h.p. Panhard (Mr. T. B. Browne); No. A10, 8 h.p. Napier (Mr. E. Kennard); Class D.—No. A11, 12 h.p. Daimler (Hon. J. S. Montagu, M.P.); No. A17,

12 h.p. Panhard (Hon. C. S. Rolls); No. A22, 12 h.p. Daimler (Mr. J. A. Holder).

B. The following completed the entire Trial, having maintained an average speed up to the legal limit, except on the undermentioned stages, respectively, viz. :—

SECTION I. CLASS A.

No. 1, Benz Ideal, second stage, $9\frac{1}{2}$ m.p.h.; sixth stage, $11\frac{1}{2}$ m.p.h.; eighth stage, 11 m.p.h.

No. 2, Benz Ideal, tenth stage, $11\frac{1}{2}$ m.p.h.; thirteenth stage, $11\frac{1}{2}$ m.p.h.

No. 27, New Orleans voiturette, fourth stage, $11\frac{1}{2}$ m.p.h.; eighth stage, 11 m.p.h.; ninth stage, 11 m.p.h.; tenth stage, 10 m.p.h.

No. 34, Décauville, fourth stage, 11 m.p.h.

No. 41, International Victoria, fourth stage, 10 m.p.h.; eighth stage, 11 m.p.h.; ninth stage, 11 m.p.h.; tenth stage, $9\frac{1}{2}$ m.p.h.

No. 44, International Victoria, ninth stage, 11 m.p.h.; tenth stage, $10\frac{1}{2}$ m.p.h.

SECTION I. CLASS B.

No. 49, Marshall Carriage, first stage, $7\frac{1}{2}$ m.p.h.; second stage, $9\frac{1}{2}$ m.p.h.; third stage, 11 m.p.h.; fourth stage, 11 m.p.h.; eighth stage, 11 m.p.h.; ninth stage, $11\frac{1}{2}$ m.p.h.; tenth stage, $5\frac{1}{2}$ m.p.h.

SECTION I. CLASS C.

No. 8, Motor Manufacturing Company's 6 h.p. phaeton, second stage, 11 m.p.h.; third stage, 10 m.p.h.; fourth stage, 10 m.p.h.; eighth stage, 11 m.p.h.; tenth stage, 10 m.p.h.

No. 26, 8 h.p. Peugeot, second stage, 9 m.p.h.

No. 36, 6 h.p. Daimler, fourth stage, 10 m.p.h.; eighth stage, $11\frac{1}{2}$ m.p.h.

No. 37, Daimler Parisian, eighth stage, 10 m.p.h.

No. 46, Richard car, fourth stage, $6\frac{1}{2}$ m.p.h.; ninth stage, 10 m.p.h.; tenth stage, $9\frac{1}{2}$ m.p.h.

No. 47, Richard car, fourth stage, $11\frac{1}{2}$ m.p.h.

SECTION II. CLASS A.

No. A25, Benz Ideal (Mrs. Bazalgette), first stage, $11\frac{1}{2}$ m.p.h.; second stage, $7\frac{1}{2}$ m.p.h.; third stage, $10\frac{1}{2}$ m.p.h.; fourth stage, $10\frac{1}{2}$ m.p.h.; sixth stage, 8 m.p.h.; eighth stage, $8\frac{1}{2}$ m.p.h.; ninth stage, $8\frac{1}{4}$ m.p.h.; tenth stage, 9 m.p.h.

SECTION II. CLASS B.

No. A24, Mors voiturette (Mr. Phillips), tenth stage, $11\frac{1}{2}$ m.p.h.

SECTION II. CLASS C.

No. A2, 6 h.p. Panhard (Mr. Butler), fourth stage, 11 m.p.h.; eighth stage, 11 m.p.h.; tenth stage, 11 m.p.h.

No. A7, 6 h.p. Daimler (Mr. A. Harmsworth), eleventh stage, 5 m.p.h.

No. A12, 6 h.p. Daimler (Mr. H. Edmunds), second stage, $11\frac{1}{2}$ m.p.h.; third stage, $11\frac{1}{2}$ m.p.h.; sixth stage, 5 m.p.h.; seventh stage, $9\frac{1}{2}$ m.p.h.; eighth stage, 10 m.p.h.; ninth stage, 10 m.p.h.; tenth stage, $9\frac{1}{2}$ m.p.h.

No. A21, 6 h.p. Daimler (Mr. E. Pitman), eleventh stage, $9\frac{1}{2}$ m.p.h.

No. A26, 6 h.p. Daimler (Mr. C. K. Gregson), eighth stage, 11 m.p.h.; tenth stage, 10 m.p.h.

No. A30, 6 h.p. Daimler (Mr. J. D. Siddeley), sixth stage, $8\frac{1}{2}$ m.p.h.

No. A31, 6 h.p. Daimler (Mr. W. Exe), ninth stage, $9\frac{1}{2}$ m.p.h.

SECTION II. CLASS E (b).

No. A28, Enfield Quadricycle (Mr. E. M. Iliffe); fourth, $11\frac{1}{2}$ m.p.h.; eighth, 11 m.p.h.; ninth, 11 m.p.h.; tenth, $11\frac{1}{2}$ m.p.h.

C. The drivers of the undermentioned vehicles have failed to supply the official records for the following stages, viz. :—

Section I. Class A.—No. 33, Décauville; no records concerning five stages, viz. : first, third, eighth, ninth, and thirteenth; on three of the remaining stages the average speed was below the legal limit, viz. : second, 11 m.p.h.; fourth, 10 m.p.h.; tenth, $9\frac{1}{2}$ m.p.h. No. 5, Locomobile steam carriage; no official records concerning one stage, viz. : tenth stage; on five of the remaining stages the average speed was below the legal limit, viz. : first,

$11\frac{1}{2}$ m.p.h.; second, 9 m.p.h.; third, 9 m.p.h.; eighth, $9\frac{1}{2}$ m.p.h.; thirteenth, $11\frac{1}{2}$ m.p.h. No. 51, Star voiturette; no official records concerning first stage, viz. : fifth stage; on one of the remaining stages the average speed was below the legal limit, viz. : sixth, 11 m.p.h.; broke swivel of axle, and consequently spring, two spokes, and two lower frame tubes, between Preston and Lancaster.

Section I. Class B.—No. 14, De Dion voiturette; no records concerning two stages, viz. : fourth and eighth; on one of the remaining stages the average speed was below the legal limit, viz. : thirteenth, $11\frac{1}{2}$ m.p.h.; broke axle between Matlock and Buxton. No. 31, Motor Car Company's Triumph; no official record concerning one stage, viz. : the fifth stage, but average speed stated by makers to be 6 m.p.h.; on one of the remaining stages the average speed was below the legal limit, viz. : tenth, 11 m.p.h. No. 24, Marshall carriage; no records concerning three stages, viz., third, fourth, and thirteenth; on nine of the remaining stages the average speed was below the legal limit, viz. : first, $7\frac{1}{2}$ m.p.h.; second, 9 m.p.h.; fifth, $11\frac{1}{2}$ m.p.h.; sixth, $10\frac{1}{2}$ m.p.h.; seventh, $9\frac{1}{2}$ m.p.h.; eighth, 9 m.p.h.; ninth, 9 m.p.h.; tenth, $5\frac{1}{2}$ m.p.h.; eleventh, $8\frac{1}{2}$ m.p.h. No. 32, Motor Car Company's Triumph; no records concerning eighth stage; on six of the remaining stages the average speed was below the legal limit, viz. : fourth, 10 m.p.h.; fifth, $9\frac{1}{2}$ m.p.h.; seventh, 9 m.p.h.; ninth, 11 m.p.h.; tenth, $8\frac{1}{2}$ m.p.h.; eleventh, $11\frac{1}{2}$ m.p.h.

Section I. Class D.—No. 22, Lanchester carriage; no official records concerning two stages, viz. : tenth and thirteenth.

Section I. Class E (a).—No. 39, Century tandem; no records concerning one stage, viz. : the first; on one of the remaining stages the average speed was below the legal limit, viz. : tenth, 11 m.p.h.

Section I. Class F.—No. 38, Daimler public service vehicle; no records concerning two stages, viz. : seventh and eighth; on eight of the remaining stages the average speed was below the legal limit, viz. : first, 9 m.p.h.; second, $5\frac{1}{2}$ m.p.h.; third, 7 m.p.h.; 4th, $6\frac{1}{2}$ m.p.h.; 6th, $8\frac{1}{2}$ m.p.h.; 9th, 11 m.p.h.; 10th, 8 m.p.h.; 13th, 8 m.p.h.

Section II. Class C.—No. A23, $6\frac{1}{2}$ h.p. Motor Manufacturing Company's phaeton (Mr. Cordingley); no records concerning six stages, viz. : first, fifth, sixth, eighth, tenth, and thirteenth; on one of the remaining stages the speed was below the legal limit, viz. : 2nd, $6\frac{1}{2}$ m.p.h.

Section II. Class D.—No. A29, 7 h.p. Peugeot (Mr. Mark Mayhew); no records concerning three stages, viz. : third, eleventh, twelfth.

Section II. Class E (a).—No. A20, Empress tricycle (Mr. H. Ashby); no records concerning one stage, viz. : the fourth.

D. The following completed only a portion of the Trial, viz. :—

Section I. Class A.—No. 19, Orient Express; broke piston-rod near Manchester; Sunday, April 29th, was occupied in repair; on Tuesday, May 1st, the counter-shaft broke on the journey from Kendal to Carlisle; it is said that between Carlisle and Edinburgh the car ran into a ditch, sustaining serious damage; it was withdrawn near Edinburgh; averages were up to the legal limit for the three days for which records are complete. No. 29, Eureka car; in difficulties several times; disappeared after Kendal; did not follow official route between Carlisle and Newcastle, for which part of the journey it has no records; has records for only five stages out of thirteen, viz. : second, 8 m.p.h.; fifth, 12 m.p.h.; sixth, $11\frac{1}{2}$ m.p.h.; eleventh, $9\frac{1}{2}$ m.p.h.; twelfth, 12 m.p.h. No. 30, Eureka car; obtained a record for the second stage only, viz. : 7 m.p.h. No. 52, Roots and Venables; a swivel axle arm was broken at Bolton, and driver sent car by train to London; has records for three stages only, two of which were up to the legal limit and remaining one $10\frac{1}{2}$ m.p.h.

Section I. Class B.—No. 11, Motor Manufacturing Company's Princess car; this car joined the Trial on the last stage only. No. 53, Wolseley carriage; ran over a few of the early stages of the Trial, but obtained no records.

Section I. Class C.—No. 45, S.S. carriage; broke front axle by running into a wall, before Manchester; has records for three stages only, two of which were up to legal limit, and

remaining one, viz.: third stage, 8½ m.p.h. No. 23, Brown-Whitney steam car; there were several mechanical defects which required remedy, the consequence being that there are, concerning this car, records for only six out of thirteen stages, two of which were up to the legal limit, the remaining four being as follows respectively, viz.: First stage, 11 m.p.h.; second stage, 6½ m.p.h.; fourth stage, 10 m.p.h.; eleventh stage, 8 m.p.h.

Section I. Class D.—No. 17, 8 h.p. Napier fitted to Panhard carriage; retired before arriving at Bristol through failure of gear. No. 21, Lanchester carriage; ran over a portion of two of the earlier stages, but was then withdrawn.

Section II. Class D.—No. A4, 8 h.p. Panhard (Mr. Mark Mayhew); no records concerning four stages, viz.: first, sixth, seventh, and eighth; on one of the remaining stages the average speed was below the legal limit, viz.: fourth, 11 m.p.h.

Section II. Class E (a).—No. A16, Ariel tricycle (Mr. A. J. Wilson); no records concerning seven stages, viz.: seventh, eighth, ninth, tenth, eleventh, twelfth, and thirteenth.

E. The following vehicles were withdrawn from competition for the reasons stated below, viz.:—

Section I. Class A.—No. 28, New Orleans Car; this vehicle completed the Trial, but was withdrawn by the owners at the Crystal Palace; there are no records of this car on five stages, viz.: third, sixth, seventh, eighth, and ninth, and of the remainder three were below the legal limit, viz.: Fourth stage, 7½ m.p.h.; fifth, 6 m.p.h.; tenth, 7½ m.p.h.; thirteenth, 11½ m.p.h.

Section I. Class A.—No. 42, London Motor-Van and Wagon Company's 3½ h.p. voiturette; on the first stage the crank shaft broke off close to the fly-wheel; crank shaft was repaired, but the vehicle did not continue to run in the Trial on account of what appears to have been some misunderstanding as to the rule as to partial records.

Section I. Class C.—No. 43, London Motor-Van and Wagon Company's Phaeton; this car ran well on the first stage, but was withdrawn at Bristol owing to withdrawal of No. 42, Section I., Class A.

Section I. Class E (a).—No. 12, Motor Manufacturing Company's Tricycle; new frame and wheels were substituted at Manchester, and a new motor was fitted to frame at Nottingham; this tricycle has since been withdrawn from the competition by the makers; No. 20, Simms' Motor Wheel; capsized on tram lines both at Bath and Bristol, and was withdrawn from competition at Gretna Green.

Section II. Class D.—No. A19, 12 h.p. Daimler (Mr. J. Hargreaves); ran through the greater portion of the Trial, but the owner does not wish to claim any records; No. A27, 12 h.p. Daimler (Mr. J. Hargreaves); ran throughout, but the owner does not wish to claim any records.

THE Aberdeen Motor Service Company are to run cars between Ballater and Braemar. As the railway terminus is at Ballater, and Braemar is largely visited by tourists, the service should prove successful.

MR. LENDON, of Beckenham, has expressed his intention of initiating a crusade against motor-cars on the ground of their alleged smell and noise. Will the automobile movement survive such a crusade? We rather fancy it will.

THE Tramway Committee of the Southampton Corporation has recommended the Council to make further investigation into the most suitable form of motor-vehicle to be placed upon the omnibus route in the town.

AT the weekly meeting of the London County Council on Tuesday an application of the Strand District Board for the loan of £1,500 for the purchase of two motor dust vans for use in the district was, on the recommendation of the Finance Committee, acceded to.

A GARDEN fête is being held at Sheen House, Richmond, in aid of the Marchioness of Lansdowne's Officers' Families Fund, and some vehicles belonging to members of the Automobile Club are taking visitors for drives in Richmond Park on the afternoon of Friday and again to-day (Saturday), the proceeds going to the fund.

THE KÜHLSTEIN ELECTRIC MAIL COACH.

IN addition to petroleum-spirit motor-cars, the Kühlstein Wagenbau Gesellschaft, of Charlottenburg, Germany, has lately been devoting attention to electrical vehicles, the accompanying illustration showing a large mail coach capable of accommodating no less than eighteen persons, lately constructed by this firm. For the propulsion of the vehicle two electro-motors of 7½ h.p. each are used—one for each of the rear wheels—and the power is transmitted by encased cog wheels. The motors are hung on the under-part of the carriage by means of springs, which thus protect the delicate parts of the mechanism from the vibration caused by the inequalities of the road. The battery is composed of eighty cells, the weight of which is 3,000 kilos., and the capacity being stated to be sufficient for a five hours' run; it can be charged 110 or 220 volts. As much depends upon the weight of the accumulators and that they should be as light as possible, this carriage is built on the principle, the relative weight of the accumulators and the carriage being 1—1; that is to say, the battery and the carriage are the same weight, namely, 3,000 kilos. each. The controller is adapted to give six speeds forward, three electric brakes and a reverse motion. The battery is arranged in two sets, and they can be rendered

quite independent of each other if necessary. The steering is effected by means of a hand-wheel in front of the driver's seat. The makers state that it has been proved by experiments with this coach, that it requires from 15 to 20 per cent. more energy to drive it when mounted on rubber tires than it does when steel tires are used; but, on the other hand, the vibration caused by the steel tires is very destructive to the machinery. The vehicle will, it is claimed, carry eighteen people a distance of sixty kilometres on one charge of the battery.

THERE is no industry at the present moment, says the *Westminster Gazette*, which gives more promise of rapid development and profit than the motor industry.

THE International Motor-Car Company announce that they are prepared to sell automobiles on the deferred payments system, and intend developing this plan of business on a large scale.

THE address of Mr. A. I. Greenwood, the hon. sec. of the Yorkshire Automobile Club, the formation of which was referred to last week, is 5, Woodhouse Lane, Leeds. The next meeting of the club will be held at the Mitre Hotel, Commercial Street, Leeds, at 8 p.m. on Friday next, and all Yorkshire automobilists are invited to attend.

MOTOR-CARS ON THE CONTINENT.

An Italian-built Motor-Car.

THE accompanying illustration shows the light three-seated car which has lately been put on the market by La Società della Fabbrica Italiana di Automobili, of Turin. The feature of the car, which is known as the "F.I.A.T.," is the location of the motor, which is placed in the rear of the frame, at right angles to the position adopted in the Benz type of cars. The engine is of the horizontal two-cylinder type, and is stated to be capable of working up to 4 h.p.; the ignition is electrical, while the cylinders are water-jacketed, a special form of pump being employed to keep up the circulation. Three speeds forward are available, a reverse motion not being fitted unless specially ordered. The location of the motor transversely in the rear of the frame is claimed to reduce the amount of vibration transmitted to the riders. The fly-wheel forms part of a friction clutch, through which the power is conveyed to a shaft in line with the motor

shaft. At its forward end this shaft carries three pinions, enclosed in an oil-containing gear case. In the latter is a small countershaft provided with three large spur-wheels, any one of which can be brought into mesh with its corresponding pinion on the main shaft. The countershaft has fitted at its rear end a bevel gear, which transmits the power to a differential cross shaft, the usual sprocket wheels and chains conveying the power to the rear road wheels. The speed and other control handles are mounted at the side of the steering pillar, steering being controlled by a bar. Ample brake power is provided, there being a pedal-operated band brake on the differential shaft, and band brakes on drums attached to the hubs of each of the rear wheels, operated by a hand lever. The frame of the car is built up of channel steel; the road wheels are of wood, shod with pneumatic tires. The car can, it is stated, attain a maximum speed of 45 kilometres per hour.

The Moto Club of France.

THE composition of the various committees of the Moto Club of France has now been in part published, and although these elections are but provisional, I quote them as giving English readers some idea as to who are really the moving spirits of the new society. The administration, or first section, is in the hands of MM. Pierre Giffard, Gobron, Trouette, Vignat, and Darracq, while MM. René Varennes, Collin Scotte, and Hérard will give their attention to all technical matters. Section number three will be devoted to the sporting side of automobilism, and to this committee MM. Paul Rousseau, Riguelle, and Archdeacon have already been elected. Touring will be looked after by MM. Lemoine, Corlin, Gautier, Cadier, and Léon Petit, and to the legal questions MM. du Laurens de la Barre, Delaunay, Nivert, and Nantet will devote their energies. Naturally, the president, M. Serpollet, and the secretary, M. Paul Meyan, will serve upon all committees. There seems to be a

good strong *Vélo* flavour in the organisation, and that paper would appear to be the official organ of the new society.

Racing in Germany.

WHILE in France automobile racing has, for the time being at any rate, sunk into nothingness, in Germany the sport is gaining ground and a number of events are set down on the automobile fixture card. Not the least interesting of these will be a motor-car race upon the track of the Frankfurter Renn Club, at Frankfort, in which it expected that some of the leading *chauffeurs* will be seen competing against such crack German racers as Held, Tischbein, and Skarisbrick. This is arranged for the 29th inst. The touring amateurs, too, have recently had an opportunity of demonstrating their skill and the speed of their cars in a race from Nuremberg to Kitzingen and back, a total distance of 160 kilometres (100 miles). This event was won by Errhard, driving a two-seated car, in 4h. 45min., the other placed men being:—Schutte (four-seated car), in 5h. 50min., Beissbarth (two-seated car), in 5h. 51min., and Kurz (two-seated car), in 6h. 25min.

Racing at Salon.

THE Automobile Club of Salon is fortunate in possessing in the immediate neighbourhood one of the most magnificent stretches of road in France, for that in itself is sufficient to tempt racing men to enter for any event promoted by this "cercle." Already this year one most successful meet at Salon has been recorded in this column, and now the history of another has to be written. It was on Sunday last that this second gathering took place, and thanks to glorious weather and capital organisation the races scored a great success. The three events set down for decision were:—1, Cars weighing 400 kilos. and upwards; 2, Motor-cycles weighing less than 250 kilos.; 3, Voiturettes weighing less than 400 kilos. Considerable disappointment was felt at the non-appearance of MM. Levegh and Antony, the two Mors champions, for a keen race between them and M. Jenatzy had been anticipated. In their absence there was really nobody to seriously extend the Belgian, who was mounted on the car which recently made such extraordinary fast time at Brussels. Among the motor-cycles Béconnais and Marcellin were installed hot favourites, but neither finished the course, the former breaking his electric connection, and the latter an induction valve. Marcellin, too, was generally expected to win the voiturette race, for his 6 h.p. was known to be capable of making 70 kilometres per hour, but here again trouble was the order of the day, and after reaching Miramas the favourite was helplessly *en panne*. By the bye, the winner in this category, Camus, was driving a voiturette of Lyonnaise construction. This car was provided with a single cylinder water-cooled motor of only 3 h.p., and yet with two persons up the hundred kilometres was covered in 1 h. 58 min., or at an average speed of 51 kilometres per hour. The route followed by all categories was from Salon to Arles and back, with a *détour* by way of Calaman and Miramas in order to make up the hundred kilometres exactly. The voiturette race was the first decided, the competitors in this class being despatched at 8 o'clock in the morning. By 11.15 five out of the six starters had accomplished the journey, the sole absentee being Marcellin. The official returns are as follow:—

			WEIGHT.	H.	M.	S.
1. Camus	...	3 h.p.	...	320 kilos., in	1	58 3 $\frac{1}{2}$
2. Hachel	...	5 h.p.	...	328 kilos., in	2	43 9 $\frac{3}{4}$
3. Chevallier	...	3 h.p.	...	400 kilos., in	2	54 21 $\frac{1}{2}$
4. Montel	...	4 h.p.	...	260 kilos., in	2	59 5
5. Felix	...	3 h.p.	...	355 kilos., in	3	15 5 $\frac{1}{2}$

The big cars left at two o'clock, and the order at the finish was—

				H.	M.	S.
1. Jenatzy	...	30 h.p.	...	in	1	20 15 $\frac{1}{2}$
2. Cûchelet	...	15 h.p.	...	in	1	33 15 $\frac{3}{4}$
3. Vagliano	...	12 h.p.	...	in	1	39 15 $\frac{3}{4}$

The average speed of Jenatzy was 75 kilometres (47 miles) per

hour. Finally the motor-cycles got under weigh, and the placed men were—

			H.	M.	S.
1. Vitalis ...	5 h.p.	...	in 1	41	28 ³ / ₅
2. De Sylvabelle ...	3 h.p.	...	in 1	44	18 ³ / ₅
3. Donjou ...	4 h.p.	...	in 1	59	16 ³ / ₅
4. Bonnard ...	motor-bicycle	...	in 2	18	24 ³ / ₅

Marcellin and Bonnard both decided to endeavour to set up new records for 100 kilomètres, each in his own particular class, and accordingly they stayed at Salon until the following day. Then Marcellin discovered his voiturette to be in too bad a condition to give him a chance of success, so Bonnard started alone. Selecting a stretch of road of 25 kilomètres in length the trial was duly commenced, and the motor-bicyclist made the following times:—25 kilomètres, 29min. 30sec.; 50 kilomètres, 63min.; 100 kilomètres, 133min. 19sec. The record of 137min. 11sec. made by Bucquet on May 31st on the Etampes road was therefore beaten by nearly 4min.

The Paris-Toulouse-Paris Race.

THIS race, which is organised in connection with the Paris Exhibition, will be run as follows:—Wednesday, 25th July, start from Montgeron at 3 a.m. for Toulouse, in one stage, 427 miles; Friday, 27th July, Toulouse to Limoges, 190 miles; Saturday, 28th July, Limoges to Montgeron, 237 miles, a total of 854 miles. The vehicles will be displayed at the Exhibition at Vincennes on the 29th, 30th, and 31st July, and 1st and 2nd August. Bronze medals will be given in respect of vehicles which complete the journey at an average speed of 24.8 miles per hour, and silver medals in respect of vehicles making an average of not less than 49.6 miles per hour. There will be three classes, viz.: carriages, voiturettes, and motor-cycles.

THE HERMITE ELECTRIC SPARK INDICATOR.

A FRENCH firm has recently introduced a device intended to show the driver of a motor-car or cycle, at a glance, the behaviour of the electric spark in the explosion chamber of the motor by causing a reproduction of it outside of the motor, and in the interior of a small glass tube mounted upon the igniter. The apparatus consists essentially of two insulated metallic rods placed in the centre of the tube and fixed to the top and bottom caps of the latter by one of their extremities, which is threaded so as to permit the distance apart of their tips to be regulated. One of these rods is secured to the sparking plug, and the other to the wires of the induction coil, by a simple arrangement. There is no danger of the occurrence of a fire, since the spark produced is protected on all sides from contact with external objects.

As the apparatus remains permanently fixed to the plug, it allows the driver, while on the road, to keep himself constantly informed as to the working of the ignition apparatus, and thus to avert the necessity of occasionally dismounting and remounting the wires of the plug or the plug itself, and consequently to avoid stoppages of his car. It permits, too, of noting the length of the spark, and thus tends to prevent the occurrence of those electric shocks that sometimes give the automobilist a painful reminder of the physiological effects of a high tension current. The device has just been introduced into this country by the London Autocar Co., of Gray's Inn Road, W.C.

EFFORTS are, it is stated, being made to organise a service of motor-omnibuses in the Spanish town of Barcelona.

THE BRITISH MOTOR COMPANY.

AN extraordinary general meeting of the British Motor Company, Ltd., was held at the Hotel Cecil, Strand, W.C., on Monday, for the purpose of considering a scheme for the reorganisation of the company. Colonel Josiah Harris, who presided, said the shareholders had been called together at the express desire of the committee of gentlemen who had investigated the affairs of the company. He formally moved the following resolutions:—(1) That the reorganisation scheme sent to the share and debenture holders, dated June 23, 1900, and the conditional agreement dated June 23, 1900, referring to the same, made between this company and Charles Osborn, as trustee for the proposed new company referred to in the said scheme (the original of which is now produced to this meeting), are hereby approved. (2) That, having regard to the said scheme and agreement, it is desirable to wind up this company, and accordingly that the British Motor Company, Ltd., be wound up voluntarily. (3) That the liquidator or liquidators of this company be, and are hereby, authorised to carry the said scheme and agreement, when approved by the debenture-holders, into effect, with such modifications (if any) as shall be agreed upon, and that he or they be authorised and required to distribute in kind amongst the members of this company, in proportion to the number of shares held by them respectively, the 451,568 shares in the new company of £1 each, credited with 17s. per share as paid up thereon, referred to in the said scheme and agreement; so that each member of this company shall be entitled to have his or her proportion thereof allotted to himself or herself or his or her nominees on claiming the same in the manner and within the time required by the liquidator or liquidators, in accordance with the said scheme and agreement.

Mr. Gill seconded the resolutions.

Mr. Harry J. Lawson said the shareholders were not met together that day because there was any falling off in the prospects of automobilism, or in the popularity of the automobile; neither were they met because the company's great patented systems—the Daimler and the De Dion—were in any less demand. They had met because the outlook at the present moment, and the popular demand for automobiles, especially their own systems, was so large and so increasing that it was a matter for immediate and serious discussion what was best to be done. He supposed all the shareholders would admit that stupendous work had been already accomplished, although it had not yet resulted in the return of any great profits to either the company or the shareholders. A little over three years ago there was not one single motor-car of English make, and there were no English factories for their manufacture. He could assure the shareholders that their work had been a most arduous and difficult one. In the short period of a little over three years factories and large mills had been equipped with special machinery working under the company's licences. It was once ignorantly believed to be one of the most simple and easy matters to build a motor-car, and that the streets would be soon full of them. He confessed that at first he was a little too sanguine on that point. They told the shareholders, three years ago, that they believed they had in their patents the very best automobile system that had been invented, and they now, at the end of the first three years, saw that their Daimler, the Panhard Daimler, and the De Dion systems were completely triumphant. Those were the three acknowledged systems which were carrying everything before them, and the patents were the property of this company. The point which they had to consider now was how they could best utilise these important inventions. The British Motor Company had never had any considerable working capital. This was a syndicate formed to hold and to develop patents, and to try and obtain a monopoly of the whole system of patents in motor-cars. It had been stated several times that private enterprise would have been sufficient; but they spent months trying what private enterprise would do. The British Motor Company, therefore, was left with only one alternative, and that was to try and obtain capital from the public to start this great industry. They managed to raise £100,000 for the Daimler Motor Company, and that company was the very first to manufacture motors in England. Its work was quite equal to Continental work. The next step they took was to form the Great Horseless Carriage Company, which was now called the Motor Manufacturing Company, and they succeeded in raising £400,000. The Motor Manufacturing Company was still going on improving its position every day. If anyone went down to Coventry, and looked at the great works there, he would see what had been done. Having learned, and being in a position to deal with the matter, a number of the shareholders lately co-operated with the directors, and insisted that the board should take some more active steps both to protect the company's patents and to start a definite policy, with which he thoroughly agreed.

Mr. Munton declared that the speech they had just listened to was an extraordinary one. With some of the remarks he concurred. For instance—that the whole thing was a speculation; and, secondly, that Mr. Lawson's main object was to make the deferred shares of value. There was no opportunity at the present time to examine the accounts. They ought to have been presented before this extraordinary meeting was held to wind up the company. He also protested against the meeting being held at eleven o'clock on Monday morning, when it was very difficult for country shareholders to attend. He knew it was useless to attempt to thwart the resolutions before them, because they would be outvoted by the proxies; but he would move: "That the meeting be adjourned for a month, and that, in the meantime, a meeting be called for the presentation of accounts, so that they might be studied by the shareholders, who would then be able to arrive at a decision whether the scheme should be carried or not."

Mr. J. R. Stevens seconded the amendment.

Mr. Wright inquired whether, in the possible event of the scheme not being carried, the directors could, adequately and properly, protect in law the patents of the company and carry on the business; or whether it was absolutely necessary that the resolutions should be passed if the business was to be continued.

Mr. Edge said he was a member of the committee, and also a proprietor in various companies which paid this company considerable sums of money every year in royalties. At this time there was a vast importation into this country by people who were infringing the patents, for which he, in his connection with other companies, was paying royalty. He therefore approached this company, and pointed out that those other companies were not prepared to go on paying large sums by way of royalty unless the British Motor Company protected its patents. The reply was that although large sums had been spent in fighting various patents, as far as the patents under which he was working were concerned they had not been fought for want of money. It was unreasonable to suppose that he and those with him in the other companies would go on paying their royalties without protection; for if the patents were not protected they became worthless. If the money were not found for their protection he and those with him would cease paying royalties, and in place of being friends of the British Motor Company would become enemies. Therefore the matter should be very seriously considered. Infringement was going on in every direction, and no action was being taken. He had looked very carefully into the patents of this company, and was satisfied they were good; but those he represented were not going to pay large sums for royalties if the patents were not going to be protected.

Mr. Hopkins asked if there would be any difficulty in presenting the accounts before the confirmatory committee, supposing the proposal for adjournment were withdrawn. He thought that that would be a more business-like proposal than to adjourn the meeting for a month. If a scheme of a more practical character than the one now submitted could be suggested, there might be some advantage in an adjournment. He was prepared to support the scheme, but he did not think money should be put up by the ordinary and preference shareholders without some guarantee that they would have control over the management.

Mr. W. A. Davis said it had been publicly reported that Mr. Lawson had parted with his interest, and severed his connection with the company. He wished to know if there was any truth in that statement. It was stated in the circular issued by the board that the new company was to take over the principal patents and assets of the company. He should like to know whether the new company intended to purchase the whole of the interests of the old company or only a portion of them.

Mr. Lawson, in reply, said the most vital question asked was whether the vendors were going to contribute any funds towards the new company. Personally, he would have to pay 3s. on nearly 50,000 preference shares, apart from the other vendors, who held 9,000 or 10,000 shares. It might be asked why the company had not gone in for omnibuses. Two omnibuses, which had taken over a year to build, were now running in London, and he had now one built which, he thought, would be far superior in every respect. He hoped it would arrive next week, and he believed it would prove a perfect success. It ran comparatively silently, and would carry thirty people. Those omnibuses took nearly a year to build, and at the present moment they cost about £1,000 each. It would require a capital of £100,000 to put fifty of those omnibuses on the streets, because half of that amount would have to go in machinery and plant, and they would probably have to wait a year and a half before they were built. It had been suggested that the directors might send out the balance-sheet to every shareholder before the confirmatory meeting. If that would meet the difficulty, he was quite willing to do so. Of course, it would not be a very rosy statement; it would not show large profits, because the principal item consisted of a long series of actions which were brought against the company over the London Steam Omnibus Company's prospectus. Hitherto they had not attempted to produce motor-cars; but, of course, if they had capital they would be able to do so. The company had the right to purchase the works in Coventry, on which a deposit had been paid; he believed they had cost £10,000 or £15,000 altogether. The lease was for a period of over eighty years, and the rent was about £40 per annum. The new company would take over the whole of the Daimler and De Dion patents, and also those patents which were more or less valuable. There were a large number of patents on which they had to pay very large renewal fees, amounting to thousands of pounds a year, and it was proposed to allow those which were not thought of any value to expire. The company had received seven new patents from the Daimler Company, and these gave the company the control of the market. He had retired from the board because he was advised that probably if he brought off a deal for this company he would get involved by being on the board, and also being a promoter of the company; at the same time, he was quite willing to join the board again the moment he had made any money for the shareholders. There was no possibility of the company being able to protect the patents unless the scheme went through and funds were provided. After some further discussion the amendment for the adjournment of the meeting was put and lost, and the original resolutions were afterwards put and carried, with a few dissentients.

A meeting of the debenture-holders was subsequently held for the purpose of considering, and, if thought fit, passing the resolutions as set forth in the notice. The Chairman formally moved the adoption of the resolutions, and, on their being put, they were declared carried by about fifty votes to seven.

FAILING TO STOP.

At Windsor, on Monday, Mr. Alfred Rawlinson, of 21, Ovington Square, London, was summoned by a van driver for an offence against the Light Locomotives Act. The complainant alleged that when the horse he was driving bolted he held up his hand and shouted to defendant to stop his motor-car, but he did not do so. Defendant denied that he saw the van-driver's signal. He stated that he headed the horse after it had bolted in order to try and stop it, but seeing that the animal continued restive he went right away from it, as he thought the horse disliked the noise of the car. The magistrates dismissed the case on the ground that defendant had not noticed the van-driver's signal, but they pointed out that a motor-car driver was bound to stop when the driver of another vehicle or a policeman held up his hand.

FRIGHTENED BY A MOTOR-CAR.

At the Atherstone County Court last week, Mr. Brydon Minion Miles, coal merchant, Atherstone, claimed £21 10s. from Mr. Walter Macfarlane, engineer in the employ of the Daimler Motor Company, Coventry, for damages to a horse. Plaintiff's case was that on April 4th his horse, whilst in Coleshill Street, became frightened, bolted and fell, by the noise of a motor-car, and that defendant did not stop when signalled to do so by plaintiff's man. The defence was that plaintiff's man did not hold up his hand until the horse had bolted. £7 10s. of the claim, for horse hire, was abandoned, as it was shown that plaintiff did not hire another horse after his own had been injured by the fall. The jury found a verdict in favour of plaintiff for £13 10s. with costs.

FURIOUS DRIVING CASE.

At the Haywards Heath Petty Sessions last week, Mr. Alfred Bunn, of Burnes, was summoned for driving a motor-tricycle at a greater speed than twelve miles an hour. P.S. Curtis said on June 3rd, on Handcross hill, he saw defendant riding a motor-tricycle. He was going very fast, from eighteen to twenty miles an hour. P.C. Adams said he saw defendant come down the hill, and signalled to him to stop. He admitted going eighteen miles an hour. Defendant said the machine was running free, and he could stop within a foot. Fined 10s. and 11s. costs.—Mr. William Duck, of Cambridge, was also summoned for driving a motor-tricycle at a greater speed than twelve miles an hour. Defendant did not appear, but sent a letter to the Bench. P.S. Curtis said on June 3rd he saw defendant come down Handcross hill. He timed him for a quarter of a mile, which he did in 45secs.—about twenty miles an hour. There was another man on the motor with defendant. Fined 15s. and costs 9s.

A COLLISION CASE.

At the Coventry County Court on Monday, Norman H. Burden, fitter, Foleshill, by his father, claimed from Thomas S. Stevens, son of Mr. J. Stevens, of Earlsdon, the sum of £9, personal injuries and damages to his cycle, caused by the defendant negligently driving a motor-cycle in Hertford Street on May 21st last. There was a counter claim by the defendant, who sued for £9 17s. 6d., damages caused to the motor-cycle by reason of the negligent riding of Burden. The jury found that the accident was caused by the negligence of the driver of the motor-cycle. They put the damages at £5 2s., judgment for plaintiff for that amount being given.

THE municipal authorities of Milan have granted a concession to Messrs. Turinelli and Company to introduce an experimental service of electric cars in the city.

AN attraction for the Manchester Wheelers' seventeenth Annual Race Meet, to be held on the 14th inst., will be a couple of motor-tricycle races. As such well-known riders as Messrs. S. F. Edge, C. Jarrott, J. W. Stocks, and F. F. Wellington are expected, the meet promises to be an interesting one.

THE Motor-Car Journal.

Vol. II.]

LONDON, SATURDAY, JULY 14, 1900.

[No. 71.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS

MR. J. GRANT-LAWSON, M.P., has been addressing the patrons of the Malton Agricultural Show on the subject of motor-cars, being constrained to speak thereon owing to the interest of his hearers in horse-breeding. He declared that mechanical vehicles were apparently increasing in number in the streets of London, and that there seemed to be some change in their character.

Four or five years ago they were competing in the cab and omnibus trade. That was a very important trade to the breeders. They did not aim at the cab and omnibus market, but every horse-breeder must sometimes fall into that market when they possessed horses with a past or horses that seemed to have no future. The competition had, however, apparently ceased. The electric cabs that once plied in the streets must have run down, and the motor-buses seem to have burst also. In place of them they saw light vans belonging to private firms who were trying the experiment of sending their parcels round in them, and the other motor-cars were largely the property of well-to-do gentlemen who always wanted to have the latest novelty. These new vehicles were seen in the parks, and even in Palace Yard, waiting to take home members of Parliament for non-horse producing districts. And after some more in the same strain Mr. Grant Lawson reminded his hearers of the Englishman's love of the horse in a way that may be taken as though he believed the motor-car to be prejudicial to the future of the horse. As a matter of fact, the motor-car is the horse's great friend, relieving him of burdens that are distressful to himself and to all who love animals.

The London Pageant.

CONSIDERABLE interest appears to be taken in the great pageant which is being organised in London on behalf of the War Funds, and so great has been the number of offers of help that it has been decided to hold the affair in September. Holidays in July and August would probably have detracted from the result of the collection, and the postponement is doubtless in the interest of the Fund. A large number of automobiles will take part in the procession, and Mr. R. W. Wallace, Q.C., the president of the Automobile Club, has joined the committee. We understand that those motor-carriages participating need not be decorated, although, of course, such ornamentation would be desirable, and that arrangements will be made for the automobiles to be kept together in the procession.

In Ireland.

TO-DAY (Saturday) the first motor-car procession from Dublin takes place, the destination being Killaloe. Having this in view and also the suggested tour of the Automobile Club in the Emerald Isle, the experience of Mr. J. W. Stocks, who has been touring the south of Ireland on a motor-quadricycle, is not without interest.

He says that generally speaking the roads are not so bad as some have pictured, but, of course, they are rather different to those enjoyed by automobilists in this country. But if the newspapers in Ireland will continue to impress the local authorities with the necessity of improving the roads a permanent good may be done to the country.

The Liverpool Self-Propelled Traffic Association.

A MEET and run of members' private carriages is being organised by the Liverpool Self-Propelled Traffic Association for Saturday, the 28th inst. The start will be from Birkenhead about noon, lunch being at Hoylake or West Kirby. Afterwards the run will be continued on through Caldy Village, along the banks of the Dee, to Heswall and Queensferry, returning to Birkenhead via Hooton. Tea will be partaken of at the Hooton Park Club.

The Motor-Vehicle Users' Defence Association.

A MEETING of the committee of this Association was held on the 10th inst. at the Automobile Club, and amongst those present were Mr. Wallace, Q.C. (in the chair), Major H. C. L. Holden, and Messrs. C. Cordingley, C. Johnson, F. F. Wellington, E. R. Shipton, and T. W. Staplee Firth. The committee voted a substantial sum towards the expenses incurred by a member who was summoned by the Lowestoft police. A large amount of general business was done, and Mr. G. R. Helmore reported a considerable accession of members.

A Parisian Passenger Service.

SOME weeks ago an automobile passenger service was established in Paris between the Gare du Nord and the Pont de l'Alma, the vehicle employed being a Scotte train. Quite recently the Prefet of Police ordered the temporary suspension of this service, but now the car has blossomed forth again, although operating in another quarter of the city. The new route is from the Place Pigalle, that spot beloved of Montmartois, to the Trocadero, and as the exterior Boulevards are followed, the distance traversed is considerable. Under existing circumstances, when all the principal Boulevards and streets of Paris are simply seething with traffic, the action of the Prefet is a wise one, for, however navigable a car of this description may be, its very bulk is a serious encumbrance in the streets. Banished temporarily to the exterior Boulevards, where the traffic is comparatively insignificant, the Scotte can yet do excellent work, and that it will perform its duties creditably no student of steam locomotion can for one minute doubt.

A Revival of Old-Time Pleasures.

AN article on electric carriages by Mr. W. Fletcher in the *Engineering Times* for July encourages the *Manchester Guardian* to hope that the day of journeys by road and of prosperous wayside inns may again be dawning. Unfortunately, the electric car can only run from thirty to fifty miles without re-charging, and thus it is at present almost useless for tour-

ing. But one need not despair of seeing the old posting inns revive with engineers and accumulators instead of horses and ostlers. The stages will be longer and the speed greater; but, remarks our contemporary, the pleasure of travelling in this way should be no less than in the days of which Dickens and Washington Irving wrote with such enthusiasm. The difficulty lies in the beginning; charging stations would not pay without numerous motors, and electric cars are useless without charging stations. Probably some great motor-car company will attack this dilemma, as has been done on a smaller scale with electric launches on the Thames. It would be easy to begin by providing stations near the large towns, which could be extended as the demand arose until the country was covered with a network of them and the roads were again as gay and thick with traffic as in the days of Mr. Weller.

An Innovation in Hunting.

A NOTABLE feature of the annual winter meeting of the Meadow Brook Hunt Club on Long Island, in the United States, was the presence of several automobiles. This was the first occasion in the American history of the sport on which the popular modern vehicle has taken its place in line with the road coach, the brake, and the whole range of sporting and road vehicles. A sight so novel naturally attracted much attention. Even the fashionable participants in the hunt, to whom automobiles are as familiar as four-in hands, could not refrain from some expressions of surprise when they saw the noiseless vehicles speeding over the Long Island roads. Before and behind the automobilists were persons in coaches, buggies, and other varieties of horse-drawn vehicles, all of whom watched them with keen interest as they skilfully steered their carriages.

Unreliable Estimates.

THE difficulty of accurately gauging the speed of vehicles when on the road has been often pointed out in police courts and elsewhere. In a case heard at Lowestoft which was defended by Mr. Staplee Firth—"solicitor to the Automobilists' Association" as he was described in the local paper—the varying estimates of much simpler matters showed to the magisterial mind the uncertainty of evidence. The length of the court room was 34 ft. When asked by Mr. Firth for the length of the room the police sergeant gave it as between 25 and 28 ft. and another witness as 48 ft. With such discrepancies in the length of a room, no wonder the Bench considered these witnesses unreliable judges of the speed of a motor-car on the public highway. At Warwick, the Borough Bench is apparently more inclined to give heed to the imagination, and evidence having been given that a motor-cycle was being driven from twenty to twenty-five miles an hour the rider was convicted despite the fact that expert evidence and the records of the 1000-mile Trial were produced. Alas! for the vagaries of those in authority.

Automobiles and Market Gardeners.

LAST week we referred to the opening that exists for motor-wagons in connection with market gardening and, curiously enough, the new number of the *Automobile Magazine* has the following on the same subject:—Whoever has seen or heard the long strings of heavily laden market-wagons lumbering their toilsome way into a great city in the wee small hours of the day, moving at a pace slower than cold molasses, will appreciate the improvement that will come with the application of the automobile to that phase of transportation. These heavily burdened teams are powerful factors in wearing out the highways, and in these days theirs is a most wasteful form of locomotion. A good strong automobile market-wagon could be constructed with sufficient motive-power to take two or three of these ordinary wagons behind it in a train and move over the ground at least twice as fast, enabling marketmen to set out at a much later hour and yet arrive with their produce at the same time as before. The cost of transportation would also be very greatly reduced.

One automobile wagon would do the work of a considerable number of horses. The introduction of the fore-carriage, which can be speedily manufactured and applied at once to existing vehicles, would greatly accelerate the change in fields of transportation like this.

Agriculturists on Automobiles.

It was last week that MM. Vilmorin and Andrieux, the well-known French horticulturists, of Verrières and Juvisy, invited the members of the International Agricultural Congress, then sitting in the Palais des Congres, in Paris, to visit their establishments. As would be expected, both plantations are rurally situated, and the railway journey being an inconvenient one to make MM. Vilmorin and Andrieux were somewhat in a quandary as to how to convey the hundred and fifty members of the congress, and it was not until an application to the Scottie Company had been made that the difficulty was solved. That society readily placed four cars at the disposal of the congress, and by this means the crowd of members were conveyed to Verrières. After lunch there the steamers carried the agriculturists to Champagne, and then on to Juvisy, the latter place being reached at six o'clock in the evening. This excursion was made on Thursday last week, and three days later a similar outing was made to the agricultural school at Grignon.

Ladies Against Unionism.

A CURIOUS question has arisen in connection with the lady automobilists of America, whose enterprise has carried them far afield. Mrs. J. J. Astor, Mrs. Gould, and Mrs. Vanderbilt recently qualified for the licence without which no motorist is allowed in the streets of New York. Now, it happens that the Engineers' Union, a branch of the Central Federated Union of America, is one of the strongest trade unions in the country, and makes a practice of driving into its fold engine-drivers of every description who dwell within the range of its jurisdiction. The ladies in question were accordingly served with the customary papers by the union, and invited to pay their subscription and sign the necessary formula of agreements and obligations. Otherwise, they were warned, they would be classed as non-unionist engineers. Mrs. Astor and Mrs. Vanderbilt were inclined to join the society if Mrs. Gould would complete the trio. That lady, however, declined the invitation, with the result that all three have decided not to comply, although it is understood the adhesion of one would secure the capitulation of the remaining two. It is a pretty little dispute, such as will afford amusement to leaders of American society, and do harm to no one.

Motor Haulage for Millers.

THE National Association of British and Irish millers have been holding their annual conference at Scarborough, where Mr. E. C. Skurry, of Swindon, read a paper on "Motor Haulage for Millers." The whole question, he said, was an important one for the trade, for if any means could be found to lighten the present very heavy animal cost of horse haulage, so much the better for their business generally. He treated the subject from a miller's point of view, and related the experiences of his firm in connection with a three-ton oil-fired steam-wagon, and compared the statistics of the cost of motor haulage in comparison with horse haulage. The figures showed a saving, roughly speaking, of £122 per annum in favour of the motor. In large businesses the balance in favour of the motor would be very large. To show the utility of a motor-vehicle and the many uses it could be put to, Mr. Skurry gave a typical week's run from the log-book. As compared with the work previously done by five horses, it showed a saving of £2 per week. The speaker discussed the various systems of motor haulage, and said that in his opinion motor haulage must be adopted by millers who wished to keep to the front in the fight against imported flour and that sent by rail from distant mills, as it enabled the miller on the spot to deliver to the customer at a less cost to himself, and a greater convenience to the buyer.

Common-Sense on the Bench.

A COUNTY-COURT judge in the United States has just given a decision in terms which might usefully be considered by similar functionaries in this country. The proprietor of a wagon brought an action against Mr. J. West, the inventor of a gasolene automobile, at Rochester, N.J., for damages caused by the former's horse being frightened by the latter's vehicle. The judge pointed out a difficulty arising from the uncertain nature of the horse. If one should find it desirable to go back to primitive methods and trek along a city street with a four-ox team and wagon of the prairie schooner variety, it would possibly cause some uneasiness in horses unused to such sights. Yet it could not be actionable, said the judge, if a runaway should result, provided due care were shown not unnecessarily to interfere with the use of the highways. Horses may take fright at conveyances that have become obsolete as well as at those which are novel; but this is one of the dangers incidental to the driving of horses, and the fact cannot be interposed as a barrier to retrogression or progress in the method of locomotion. Fancy Justice Bigham taking such a view.

The Literature of Automobilmism.

THE literature of automobilism is growing in this country, and the forthcoming publishing season will see three or four important publications on the subject. Among these will be "Horseless Carriages, Automobiles and Motor-Cycles," by Mr. G. D. Hiscox, who is preparing a profusely illustrated octavo volume. An interesting work just published is a translation by Mr. R. B. Marston from the German. Some time ago Colonel Otfried Lauviz of the German army wrote a book on the utilisation of the automobile by the military authorities for transport purposes, and this has been translated by Mr. Marston. It is published under the title of "Mechanical Traction in War for Road Transport."

Advising Buyers.

FREQUENTLY we receive letters from readers asking for advice as to which is the best motor-car, the most suitable vehicle for invalids, the car that is specially adapted for country lanes, etc. All such queries however cannot be answered in our columns for the simple reason that so many circumstances have to be considered. The prices of cars have a long range; some may be ideal vehicles for ordinary work in fairly level country, and prove considerably less efficient when used in hilly districts with twice as many passengers aboard. Then, too, the mechanical aptitude of the intending purchaser should not be overlooked, and, altogether, any particular opinion cannot be regarded as so satisfactory as a personal trial of a car. Manufacturers now issue such full particulars of their vehicles and afford opportunities for trials that buyers can easily make a selection of the leading types, and personal experience should do the rest.

An Interesting Volume.

MESSRS. HUGUET AND MINART, of Paris, have sent us a copy of the "Grand Album Illustré de l'Industrie Automobile" they have recently issued. The work, which is elaborately got up, is devoted to a review of the latest productions of the leading automobile constructors in France. The left-hand pages are occupied with large-size illustrations of the various vehicles—petrol, steam, and electric—while the description of the same is given on the right-hand pages in three languages—French, English, and German. The book opens with a chapter devoted to some historical notes on the progress of the automobile movement, including some interesting pictures, as, for example, a Panhard car built as far back as 1880, a Serpollet steam car, a Peugeot car built in 1891, and the original Benz motor-tricycle. Then follow a couple of pages of amusing caricatures dating from the early part of the present century. Altogether, the work is most interesting; and though its size is rather large, it should form an attractive addition to the automobilist's reference library.

Satirical.

WE learn from a Transatlantic source that the Automobile Club of Columbia University has elected Mr. J. W. Masury to membership on the ground that although he has had his automobile only two weeks he has been arrested twice for "scorching," and has participated in four accidents.

A Jumping Automobile Wanted.

IT is commonly and rightly assumed that the limitations of the automobile are such as to render it of value for military purposes mainly in connection with transport arrangements. The same fact is gratifying to huntsmen, who recognise the advantage possessed by the horse in his ability to leap over obstacles and to jump ditches where the motor-car would prove worse than helpless. Already some of the journalists not engaged in looking after war news are making suggestions for the greater usefulness of the motor-car, and one has proposed that a fence-jumping attachment should be fitted. It should be arranged so that by pressing a button the machine would instantly leap over a fence instead of jumping into it. Not at all a bad idea; but its realisation is, like the task of teaching certain writers to regard automobilism as a serious matter, a rather long and tedious experiment.

MR. STAPLEE FIRTH AND MR. C. CORDINGLEY ON A LOCOMOBILE STEAM CAR.

The Great North Road.

THE old North Road went through Royston, Huntingdon, Newark, Worksop, Doncaster, and Tadcaster to York; subsequently the route was taken through Hatfield, Baldock, Newark, and Retford to Doncaster. The present route by Hitchin went at one time by Upper Caldecote, but it is now taken through Langford. Famous as it once was for coaches, the great North Road is likely to be much used by motorists; hence the value of the Great North Road map which Mr. H. R. G. Inglis has published through Messrs. Gall and Inglis. The first part takes us as far as York, and although the map is 8 feet in length, it is small enough for the pocket. It contains an index, measurement table, notes on scenery, objects of interest, and a list of hotels. There are interesting notes regarding the old coaches on the road, which show that in 1889 the fastest cyclist from London to York did not beat the daily record of the mail coach. Travellers to York will find this a most useful companion, as this one map will give all that is required on the journey.

AN AUTOMOBILISTS' GARDEN PARTY.

THE weather has recently been so fitful and unsettled, rain and wind dispiriting pleasure seekers and disappointing those who have endeavoured to minister to the amusement of others, that it was rather a daring thing for Mr. and Mrs. Herbert de Stern to have invited the members of the Automobile Club to a garden party at Strawberry Hill, Twickenham, on Tuesday last. Fortunately, however, they were warmly favoured, and the afternoon chosen for the pleasant function was one of those rare times pictured by Shelley—

When the soft winds and sunny skies
With the green earth harmonise.

There are literary associations about Twickenham, where Pope lived, and at Strawberry Hill House, which is not far away, equally interesting are the recollections of the eighteenth century poets and their friends. Strawberry Hill House, where Mr. de Stern now resides, was built by Horace Walpole on land purchased in 1747, and completed in subsequent years, the library or great parlour being finished in 1753, and the gallery round tower seven years later. In more recent years the late Countess Waldegrave considerably enlarged the house, and in 1842 the traces of Walpole's residence were removed, the great collections which he had formed being then sold by auction. All the furniture and art treasures had been of the greatest elegance and beauty, and although experts have differed as to the architectural features of Strawberry Hill House the testimony to the delightful taste with which it was decorated by its famous owner was universal, even among the most captious eighteenth-century critics.

Very different was the scene presented on the lawn last Tuesday to that which the house had seen in earlier days, although the desire of the noble owner to have given entertainment to his guests could not have exceeded that shown by Mr. and Mrs. de Stern. All members of the Automobile Club owning vehicles were invited to the party, and invitations were also given to a luncheon.

The afternoon was simply an ideal one for such an affair, and the scene on the springy lawn, which is admirably bounded by trees, was one of unusual brightness, the keenness of the sun's rays lighting up every bush and branch and sending long shadows across the short cropped grass. Within the house was much to be seen and enjoyed in the way of furniture and ornamentation, whilst clairvoyance, palmistry, and simultaneous violin and piano playing attracted many to seek the coolness of the splendid apartments. On the lawn a fountain was playing, and Signor Bocchi's orchestra of thirty-five artistes discoursed a long programme of classical music, while "The Follies" (a quintet of talented artistes) gave a varied programme of songs, duets, mandoline solos, etc., in delightful fashion. Under a tent many found cooling delights and light refreshments, and conversation made the hours fly swiftly enough.

As the cars arrived they were driven to a shady corner, from whence several made trips round the lawn during the afternoon, their owners exhibiting driving prowess and informing visitors as to various points of mechanism, although it must be confessed the fun of a sharp run round an awkward corner or circling in and about two rows of dummies which had been set up along the short avenue of trees at the lower end of the lawn seemed the favourite pastimes of the fair visitors—of whom there were not a few.

As drivers two ladies specially distinguished themselves, Mrs. Mary E. Kennard driving her De Dion voiturette and Miss Butler driving Mr. F. H. Butler's 6 h.p. Panhard, which, with its white paint, was one of the most effective-looking cars on the lawn. Captain Langrishe was also prominent among the drivers, careering around on his Peugeot accompanied by one or more ladies, and evidently regarded, as he really is, as one of the experts present. Mr. Edmunds came on his Daimler, Mr. C. Cordingley on his Marlborough phaeton, Mr. T. B. Browne on his Panhard, Mr. Arthur Mulliner on his Daimler, Mr. Ledger on his Daimler, and Mr. Grahame White on his Twin Daimler. Mr. Johnson drove Mr. Hutton's Mayfair voiturette, in which he had made an appearance at the Godstone hill-climbing on Saturday. The Hon. C. S. Rolls came on his

Panhard, the neat, stylish finish of which was much admired. There were also present a De Dion voiturette, a quadricycle, a motor-tricycle, a Clift electric car, and two other Benz cars. The Hon. Cecil Duncombe was one of the later arrivals, coming to Strawberry Hill on his Delahaye car; Mr. Hodges drove his voiturette; a 6 h.p. Benz victoria and Mr. Buttemer's car completed an enumeration of the cars we made about six o'clock. Later, Mr. Mark Mayhew arrived. Thus it will be seen that the invitations were accepted by many leading automobilists, and with Mr. Roger Wallace arriving later the Automobile Club was able to congratulate itself on a representative muster.

It had been arranged that three races should be run between six and seven o'clock for three silver cups presented by Mr. de Stern, but the preliminaries took some time, and it was nearly eight o'clock ere the competitions were in full swing. The first contest was a ladies' race in and out among half a dozen dummies placed in a row and, having turned, to return in a straight line to the starting point. There were only two entries, Mrs. Kennard and Miss Butler. At the first try the latter got well away, but Mrs. Kennard's machine declined to move, and a second start was ordered. This time Miss Butler's Panhard proved refractory, and again it was decided to make a fresh attempt. But, alas! the Panhard had not been coaxed enough. On the fourth start both ladies got away together, Miss Butler ultimately winning by about the length of her rival's car.

Then came the contests limited to gentlemen, and Mr. Hodges, on his Brierre voiturette, and Mr. Lyon Sampson, on his Benz victoria, faced the course, the former winning in good style. In the next contest, between the Hon. C. S. Rolls and Mr. Mark Mayhew, great interest was evinced, but unfortunately the latter was late in getting away at the first start, and a restart was made, when the winner of the gold medal of the Automobile Club's 1,000-mile Trial achieved distinction.

The concluding competitions were in the nature of control contests. Starting from the lower end of the lawn the competitors had to bring the front wheels of their machines over a rope and stop dead in front of a row of sticks placed parallel to the rope, but about three feet beyond. For this contest six cars appeared. Two heats were arranged, the result of the first heat being—1, Captain Langrishe, with two passengers; 2, Mr. Mark Mayhew; 3, Mr. Buttemer. The second heat resulted as follows:—1, Hon. C. S. Rolls; 2, Mr. T. B. Browne, with one passenger; 3, Mr. Frank H. Butler, with one passenger. The came the final between the Hon. C. S. Rolls and Captain Langrishe, the former again securing a first position.

With that the sports ended, and the gathering, which had been gradually melting away, dispersed altogether, the motorists going on their cars and a large contingent returning to town by train. The evening was becoming delightfully cool, and the ground presented a beautiful aspect, the darkening tints of green growing deeper and deeper with the waning of the sun. Although nearly a score of cars had been running round the lawn four or five hours the marks were few, save at one corner, where the softness of the ground led to a few slight ruts. Thanks to pneumatic tires the lawn was practically undisturbed—a fact that should be recognised by those who try to see in automobilism a means for destroying the roadway and highway of our country. Had only one or two horse-drawn vehicles been making a few journeys across the greensward the result would have been far more distressing to the gardeners of Strawberry Hill House, a spot that is now well placed among the pleasant memories of those associated with the Automobile Club.

THE members of the Manchester Automobile Club are to-day (Saturday) participating in a run to Nantwich.

THE Frankfort Automobile Club is organising a decorated automobile parade, to be held in Frankfort-on-Main, Germany, on the 22nd inst.

THE attractiveness of the motor-car as a stage feature finds another instance in its use in the spectacular operetta "The World Reversed," which is being played to crowded houses at a Berlin theatre.

THE PARIS-SINGER PETROLEUM-SPIRIT MOTOR-VOITURETTE.

THE other day a representative of the *Motor-Car Journal* paid a visit to the works of Messrs. Paris Singer, Limited, of Manor Street, Clapham, in order to inspect the new light voiturette the company has lately completed, and of which an illustration is given herewith. The car being out in use at the time we arrived, the interval of waiting for it was pleasantly filled up by the kindness of Mr. R. M. Campbell, M.I.M.E., the works manager, who conducted us over the workshops, and pointed out the various motors and cars in course of construction, of which there are not a few.

The voiturette is a comfortable two-seated vehicle, and that it is quiet in its running we can affirm as a result of the trip we took on the car. The motor is of the horizontal, two-cylinder type of $4\frac{1}{2}$ h.p., the diameter of the cylinders being $3\frac{1}{2}$ in. by $4\frac{1}{2}$ in. stroke. The normal speed of the engine is 760 revolutions per minute, the ignition is electrical, while the cylinders are water-jacketed. The inlet valves are operated automatically in the usual way. The exhaust valves are actuated independently by means of separately driven cams, which are placed—together with their gear wheels—inside the crank chamber; by this arrangement they are not only kept free from dust and grit, but are, it is claimed, rendered more silent. The valves can be readily removed for inspection, etc., at any time by merely unscrewing two bolts. The motor is fitted with a centrifugal governor which is attached to the fly-wheel, and which controls the explosive mixture supply to the admission valves; the governor acts upon a double-ported valve, of the piston type, and can be adjusted to any desired speed; it thus noiselessly controls the quantity of explosive mixture which passes into the combustion chambers centrally. The motor is located at the rear of the car, and is supported on a channel steel frame. The exhaust box or silencer is of a special pattern, and consists of a large and a small chamber and of baffling arrangements, which produce a very effective result without causing any undue back pressure.

The water for cooling the cylinder is carried in a tank, holding about five gallons, which is fixed inside the ventilated bonnet in the fore part of the car. An annular space is provided round the tank, and the ventilators are designed to admit as much air as possible when the car is running. A radiator is placed immediately under the water tank, and the water is circulated from the tank through the jackets, and through the radiator back to the tank by means of an aluminium rotary pump, driven from the motor shaft by means of a chain.

Coming now to the transmission gear, three speeds forward, six, eleven, and twenty-three miles per hour are provided; two of these speeds are obtained by $1\frac{3}{4}$ -in. belts, running on fast and loose pulleys, and the lowest gear is of the epicyclic type, although it is not arranged in quite the usual manner. The belts transmit the power direct from the crank-shaft of the engine to a counter-shaft, and the latter, which is fitted with a differential gear, drives the rear wheels of the car by means of roller chains. Provision is made for readily taking up any slack, either in the chains or the belts. The two belt pulleys on the crank shaft are arranged one on each side of the motor, while with the view of reducing the weight the loose pulleys on the differential shaft are made of aluminium. The second and third speeds are controlled by a hand lever at the side of the car, working in a rack. The belt-shifting forks are carried on a spring bar in such a way that both belts cannot be put on the fast pulleys at the same time. One of the interesting features of the car is the first speed; this is controlled by a special foot-pedal, and is so arranged as to give, by the pressure of the foot, any desired speed from nil to six miles per hour. It forms one of the best devices of the kind we have met with for driving through traffic, as, without moving anything but the foot-pedal, the car can be stopped and driven up to six miles per hour. The hand-lever at the side need only be touched when it is necessary to throw in or out the second and third speeds. Unfortunately we are not able to describe clearly how this is effected, but we may

mention that it is achieved by means of the epicyclic gear contained within the slow speed pulley on the differential shaft, the foot-pedal retarding by means of a band brake that concentric element of the gearing which causes the epicyclic train to transmit energy to the counter-shaft. The brake, which can either be made to entirely prevent this element from revolving, or can be caused to vary its speed of rotation, enables the car to be started gradually, and to travel at any desired speed of the limit of 6 h.p., the speed of the engine remaining constant.

Steering is controlled by means of a wheel mounted upon a sloping standard, the latter being entirely free from any other mechanism-controlling attachments. The method employed for communicating its movement to the front road wheels is of the double chain and chain wheel variety. The frame is spring suspended on the axles, the road wheels are of the cycle type, shod with pneumatic tyre. The petrol is carried in two tanks, which are placed on either side of the car, inside the body. The tanks are interconnected by means of an equalising pipe, and are arranged so that the motor will still continue to obtain its fuel, whether the car is on a flat or arched road, so long as there is any petrol left in the supply tanks, the capacity of which is sufficient for a run of 100 miles. As we have stated, the voiturette runs exceedingly quiet, in fact it is almost as noiseless as many electrically-propelled vehicles. Its length over all is 6ft. 8in.; width over all, 4ft. 6in.; while the wheel base is 3ft. 9in. The weight complete is about $7\frac{1}{2}$ cwt.

While at Messrs. Paris Singer's works we were shown a new two-cylinder vertical motor, of 9 h.p., the company are building. In this engine each of the exhaust valves are being separately operated, the cam gear being contained within the crank chamber. The two cylinders are cast in one piece, while a new feature is the provision of a central bearing for the crank shaft within the oil chamber. The engine has cylinders $4\frac{1}{2}$ in. in diameter by $6\frac{1}{2}$ in. stroke, the normal speed being 760 revolutions per minute.

LIVERIED MENIAL: "Me lud, the carriage waits without." Lord Fitz Josher: "Without what?" L. M.: "Without horses, me lud: 'tis an automobile."—*Chicago Record*.

MR. W. NISBET BLAIR, engineer and surveyor to the St. Pancras Vestry, is of opinion that so long as horse traction continues we shall be unable to keep our streets in a condition undeserving complaint. He fears there will be no material improvement in the cleansing of our streets until motor traffic becomes general.

CALLING in at the Automobile Palace, on Holborn Viaduct, the other afternoon, we found that Mr. Friswell had just returned from Paris, bringing with him a large assortment of accessories for the various carriages upon the English market. Mr. Friswell also informs us that he has secured the sole agency for Great Britain for the popular Renault voiturette, and for the Brierre car, both of which have been illustrated in these columns.

HILL-CLIMBING AT GODSTONE GREEN.

FAVOURED by good weather the initial effort of the recently-formed English Motor Club, on Saturday last, proved an unqualified success. By noon several cars and cycles had already arrived in order to take part in, or be present at the hill-climbing competition at Tilburstow Hill, and all through the afternoon the "toot-toot" of the motor horns was a familiar sound which found many an echo from among the members of the numerous beanfeasting parties met with between Purley and Godstone. By the time we reached the latter place, at about half-past three, the old hostelry, the Clayton Arms Hotel, which formed the club's headquarters for the time being, presented a very lively scene. Quite a number of the local inhabitants turned out for the event, including several gentlemen on horseback, who between themselves were speculating as to the chance of the "motors" getting up the hill at a speed of more than four miles per hour. Another gentleman who watched the proceedings with interest was Mr. J. George-Powell, the district surveyor, and from what we could gather it will not be long before he joins the ever-increasing army of automobilists. It would be impossible for us to give the names of all those who were present at the gathering, but we may remark that it was exceedingly well supported by motor men. Indeed, at one time, in the yard of the Clayton Arms we counted no less than sixteen motor-cycles and ten motor-cars, and although the hostelry is one of the oldest in the district, dating from the days of Richard II., it is doubtful if its courtyard ever presented such a picture of animation as it did on Saturday last.

The *locale* of the competition was Tilburstow Hill, and about four o'clock a move was made to the starting point at the foot, the interested spectators taking up positions at points of vantage along the course. The gradients of the hill from the bridge at the foot are—1 in 17 for 408 yards, 1 in 13 for 333 yards, 1 in 11.9 for 175 yards, 1 in 11.5 for 38 yards, and 1 in 87 for 260 yards to the summit. To make the course just two-thirds of a mile the finishing point was fixed 41 yards short of the summit.

As has already been stated in these columns, the competition was divided into the following sections:—(A) tricycles and quadricycles, list price of which shall not exceed £140; (B) voituresses, list price of which shall not exceed £150; (C) voituresses, list price of which shall not exceed £250; (D) cars, list price of which shall be between £250 and £500; (E) any car costing more than £500. When the list of entries was closed it

was found that in Class A seventeen machines had been entered, in Class B nil, in Class C four, in Class D two, and in Class E three, a total of twenty-six, out of which twenty-three actually started.

Taking up a position on the short, stiff portion of 1 in 11.5, not far from the finishing point, we had an excellent opportunity of watching the behaviour of the cycles and cars which were despatched from the bridge at intervals of three minutes. The cycles led off, and here the high-powered machines—some being fitted with motors of from 5 to 6 h.p.—were easily distinguishable by the ease with which they ascended the hill; the riders of most of the lower-powered tricycles finding it, of course, necessary to pedal for all they were worth. Some amusement was afforded the spectators in one of the intervals by the arrival of a tandem tricycle of the early eighties, ridden by two country joskins—one of whom, by the way, had a wooden leg—who had affixed a numbered card to their machine. Although not favoured by an up-to-date cycle with pneumatic tires, it was

evident that the two riders felt extremely proud of their performance on their old solid-tired crock. The first of the cars to pass us was No. 21, a Delahaye voituress, driven by Mr. G. D. Barnes, who had a gentleman at his side. Then came Mr. A. W. Goodwin on a De Dion voituress (No. 33), fitted with a Motor Manufacturing water-cooled motor, followed quickly by Mr. V. Lee on another De Dion voituress (No. 20). Then came the car which during the whole afternoon was the centre of attraction—No. 32, the 16 h.p. Napier. Mr. S. F. Edge was the driver and only

THE CLAYTON ARMS HOTEL AT GODSTONE.

passenger—if we omit the dog—the vehicle taking the hill at a good speed. Mr. Edge gone, the next car to come into view was the Rougemont wagonette (No. 26) of the Daimler Motor Company. The vehicle was carrying a load of six persons, including the driver, and although the pace was rather slow the summit was reached without it being necessary to "shed" any of the passengers. Just by where we were standing Mr. Lord's 12 h.p. Peugeot (No. 30) passed by No. 26, and although somewhat noisy was travelling at a fair pace. The cars were now coming along in rapid succession, for quickly on the heels of No. 30 came Mr. H. Weguelin's 12 h.p. Panhard (No. 31), with two up, and Mr. F. F. Wellington's 6 h.p. Daimler wagonette (No. 25). Although the speed of the latter was slow it is noteworthy that this car safely carried its heavy load of eight persons to the top of the hill. Finally the youngest of the competitors came along—Master Cusins—on a De Dion trike (No. 12), but although he succeeded in reaching the top it was with great difficulty, owing to the traffic, for the spectators had begun to make their way back to Godstone on motor-cars, cycles, and afoot as soon as Mr. Wellington's car had passed.

On reaching the Clayton Arms we found that the number of visitors on cars had largely increased, and a pleasant hour was spent, awaiting the results of the competition, in chatting over the events of the day. Ascertaining the results was not a matter of a few moments, for in each section they were determined not merely by taking the fastest time, but by taking the best time in relation to the selling price of the car and the number of passengers carried, a special prize being also offered to the driver of

* Also awarded prize for fastest time over course.

It will be noticed that in several cases it was not the fastest cars which secured the premier positions in the awards; this

arises, as already pointed out, from the fact that time was only one of the factors which the judges had to consider in arriving at their decisions. The times were taken by Mr. F. T. Bidlake and Mr. H. J. Swindley.

Relatively very few of the competitors and visitors stayed for the dinner at the Clayton Arms, which followed the competition, but the repast in the ancient *salle* of the hostelry with its quaint old ceiling and decorations was not the least pleasant part of the day's proceedings. About twenty-six sat down to the dinner, among this number being Mr. C. Jarrott (in the chair), the Hon. C. S. Rolls, Mr. F. W. Baily, Mr. S. F. Edge, Mr. G. H. Smith, Mr. F. F. Wellington, Mr. Napier, Mr. Holroyd Smith, Mr. C. Johnson, the secretary of the A.C.G.B.I., and Mr. J. Ernest Hutton. We place the names of these two gentlemen last designedly, for did not they come in last, amidst the cheers of the diners? Mr. Hutton had gone down to Godstone on his new voiturette, and when the dinner gong was sounded this gentleman and Mr. Johnson were not to be found. Enquiries resulted in the information that the latter had gone off to enjoy a short experimental trip with Mr. Hutton on the new car. But if their going was silent their return was noisy, for the sight of Mr. Hutton calmly steering the voiturette while Mr. Johnson was performing the work of the motor by pushing behind was too much for the diners, who made a hasty rush for the windows to welcome home the fractious motor-car and its riders. It turned out that Mr. Hutton had only got possession of the car the same morning, and that the carburettor, probably due to his short acquaintance with it, had been giving trouble. There was no ceremony at the dinner, for the chairman, Mr. Jarrott, had to be called upon by Mr. Baily to read the results of the competition, and he in turn deputed the work to Mr. Smith! The only toast was that of the gentlemen who had assisted the English Motor Club during the afternoon in carrying through its first competition, which was admitted by all to have been a great success.

Shortly after 8 p.m. a move was made for the courtyard, in which, in a few moments, the now familiar sound of motors in operation was heard, and one by one the motor-vehicles, each with its complement of passengers, took their departure to various destinations, while others not so fortunate made their way home awheel or by train.

DURING his stay at Contrexeville, France, the Shah of Persia has been interesting himself in motor-cars. The other day he sent for some vehicles, being desirous, it is stated, of taking some back with him to Persia.

"F. C. G." is referred to the work on "Gas and Oil Engines," by Mr. Dugald Clerk (London: Longmans, Green and Co.); and "Modern Gas and Oil Engines," by Mr. Frederick Grover (Manchester: John Heywood).

ON Saturday, the 26th May, Mr. Geo. L. Weiss, of Cleveland, O., and Messrs. J. W. Packard, of Warren, O., made a trip from Cleveland to Buffalo in an automobile built by the New York and Ohio Company, of Warren, O. The departure from Cleveland was made at 5 a.m., and Buffalo was reached before 9 p.m. The actual running time was thirteen and a half hours, and the distance covered 225 miles. Ashtabula, approximately sixty miles from Cleveland, was reached in three hours' running time, and Erie, 100 miles, in six hours. The last thirty miles of the run into Buffalo was, states the *Horseless Age*, made after dark on strange roads, necessitating a greatly reduced speed. The roads in general were good, at which times a speed of eighteen to twenty-two miles an hour, the maximum for which the carriage is geared, was easily maintained. Some very bad stretches of road, however, were met with, and the hills, while few in number, were of heavy grade. Considerable amusement was afforded the travellers by their being practically refused accommodation at one of the prominent Buffalo hotels where they first applied. This was doubtless on account of their travel-stained and begrimed appearance, although the usual plea was made that they had no suitable rooms to let.

CORRESPONDENCE.

DOES PETROL DETERIORATE?

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Can any of your readers inform me if the results to be obtained from petrol in driving a motor-car are dependent solely upon the specific gravity of the spirit? also, if petrol deteriorates in its explosive effects if exposed to atmospheric air? There are two spirits on the market, both of almost identical specific gravity, and yet I get better results from one than from the other. For obvious reasons I cannot give names. Yours truly,

East Molesey,

W. W. HARDWICKE, M.D.

July 4th, 1900.

A PIONEER AUSTRALIAN MOTOR-CAR JOURNEY.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—The Thomson steam motor-phaeton, which has become so well known in the colonies, has just completed the first long-distance journey in Australia, successfully negotiating the distance from Bathurst (N.S.W.), where the car had been exhibited, to Melbourne (Vic.), a distance of 493½ miles net.

The journey, for the main part, was made over rough unmade roads, sometimes being nothing but bush track, and in the whole distance not more than 150 miles of metal road existed. Some of this metal road was frightfully cut up by recent rains (two inches having fallen in fifteen hours), in one place a bridge over a creek being washed away, and it was necessary to ford it to enable the car to continue its journey. Twice we, Mr. H. Thomson, the inventor, and self, got "bushed," not being able to define the road leading through the bush, and once, just at nightfall, a chain of swamps blocked the road, the wheels being up to the axles in water and mud at times, preventing further progress. No houses being nearer than ten miles made matters worse, but chancing to fall in with some sheep drovers, we camped out in the cold, frosty night. Not only were the roads so rough and unmade, but patches of red clay bogs, which had to be crossed, were nasty obstacles, as the tires gradually grew to enormous sizes by the surface clay sticking to them. Notwithstanding these obstacles, however, the car got through to Melbourne without accident of any kind to the machinery, the only casualties being the fracture of two chain adjustment strut clips to the back axle—caused by the excessively heavy and rough country roads—and through grazing a fence a few of the under gear rods were bent, these, however, being straightened and replaced in twenty minutes.

Throughout the first part of the journey the weather was first class, but the last two days were wet and miserable. Nevertheless the progress of the car was not impeded to any marked extent, yet, as may be naturally supposed, the average speed was not high in comparison with modern cars over splendid English and French roads. The time for the whole distance was fifty-six hours thirty-six minutes, averaging 8.72 miles per hour, which, though seemingly small, is likely to remain a record for the route, it being recognised as almost impassable for motor-cars. It was intended to run from Sydney to Melbourne, but having to go to Bathurst, the plans were amended, hence the journey over one of the worst stretches of road in the colonies by an experiment vehicle and one quite unsuited for such long-distance work.

The vehicle used was a Thomson steam phaeton—the first one built in the colonies—the motor being compound 1½ in. and 3 in. cylinders by 3 in. stroke. The steam generator is novel and simple, measures 1½ cubic ft., and is worked at 250 lb to 300 lb. pressure, the production of steam from kerosene being automatic. The car is provided with sufficient condensers, re-using the steam, and the steering is effected by a side lever which does not vibrate like the central steering lever. The consumption of kerosene on the journey was 42 gallons, averaging .084 gallons per mile—by no means high when the heavy nature of the roads is taken into consideration, as well as the weight of vehicle, tools, luggage, and the two passengers, viz.: 16 cwt. Dunlop tires were used

throughout, with remarkable success—only one puncture—which was a very small item as the tires had been on the car for over 2,000 miles.

Yours truly,

E. L. HOLMES.

305, Flinders Lane, Melbourne, Vic.

June 4th, 1900.

THE USE OF ALUMINIUM IN MOTOR AND MOTOR-CAR CONSTRUCTION.

AS there would appear to be some doubt in the mind of many designers of motors and motor-vehicles as to whether aluminium is a suitable metal to use in connection with the construction of motors and automobiles, we thought the practical knowledge of what is really being done would be a better answer than all the theory that could be brought to bear on the matter. We have, therefore, taken the matter up with Messrs. W. Mills and Co., of the Atlas Works, Sunderland, who have made a speciality of casting this metal and its alloys for some years past, and have paid special attention to the motor industry. They inform us they are very busy in their foundry with all kinds of motor-car castings, the best proof of the success achieved being that they have hardly ever had a casting returned as faulty, and have never known a breakdown after fitting. Aluminium has its uses the same as any other metal. It is not expected to take the place of wrought iron and steel except in special cases, but it can be used to great advantage in almost every part where cast iron or brass are at present used, on account of it being fully the same strength and only being one-third the weight.

Aluminium castings can be used in such parts as the following, and are used by the leading makers for these parts:—Engine base and sole plates, air vessels and regulators, cylinder jacket covers, gear cases of all kinds, brackets, cylinder base chambers, steering wheels, engine covers and doors, silencer, float chambers, crank chambers, vapourisers, etc. Sheet aluminium can be used for such parts as carriage body panels, etc. Pure aluminium would be practically useless for such castings as are named, and it is only by the casting of suitable alloys that builders have been able to use the metal so largely as is now the case.

SEVERAL French Panhards have lately come to this country and among the latest we have seen is one painted olive green and driven by a French driver. It has four cylinders and pneumatic tires.

PLANS are being formulated by a committee of the Automobile Club of America for a system of tests which will show the true power and efficiency, the mechanical excellence in general and of various details of automobiles in use. Builders and users will be asked to submit their automobiles for such trials as may be planned.

THE New York *World* has recently introduced the automobile into its circulation service for carrying and delivering newspapers in New York and vicinity. One of the first of a large number ordered from the Woods Motor Vehicle Company is now being used for the purpose, having been tested under various conditions, with most satisfactory results. The machine has answered all the requirements imposed by weight carrying, grade climbing and speed, and will obviate the thousand and one difficulties incident to the employment of horses in this capacity.

THE Crest Manufacturing Co., of Cambridgeport, Mass., are putting on the market a new design of sparking plug that is claimed to be not affected by heat and expansion, and is unbreakable. The material used in this plug is a perfect electrical non-conductor, and does not expand under intense heat. It is tough, and not brittle like porcelain. The device consists of a shell of steel having a thread at one end to screw in the orifice of the chamber of the motor. The plug proper consists of a light cone of the new material, which is inserted in the steel plug. This cone fits tight in the shell, making a gas-tight joint, without packing. Through this cone a wire is passed, terminating at the bottom of the plug with an enlarged head. A platinum wire is inserted in the body of the steel shell, the spark jumping across between the two points.

PARIS EXHIBITION NOTES.

(FROM OUR OWN CORRESPONDENT.)

(Continued from page 316.)

COMPLETE as are the Exhibition arrangements in many respects they are woefully lacking in others, and one cause of complaint is the absence of numbers on the stands, thus rendering the indication of the whereabouts of any particular firm's exhibits a matter of extreme difficulty, if not of impossibility. The lack of space, too, at Champ de Mars has necessitated a veritable crowding of exhibitors, and many

THE GEORGES RICHARD DUC.

well-known firms have stands of very moderate dimensions hidden away in obscure corners. In many cases also a firm's exhibit consists of a single carriage, so it will be readily understood that a really careful examination of the section is necessary to insure a sight of the production of every exposing firm.

One of the most extensive shows is that of the Société des Etablissements Georges Richard, and, moreover, it is a particu-

FRAME OF GEORGES RICHARD CAR.

cularly interesting one. First of all there is a beautifully finished *chassis automoteur*, or motor and frame of 7 h.p., and as it is only within the last few months that the new Georges Richard car has made its appearance in England, a few remarks upon this type of vehicle may not be out of place. The 7 h.p. and the 10 h.p. motors are of the same type, the only difference being the diameter of

the cylinder and the length of the stroke. A horizontal engine of two cylinders with cranks disposed at 180deg., the motor is placed in the fore part of the frame, where, by reason of excellent balancing, it gives rise to but little vibration. The carburettor employed is extremely sensitive, and variation of the explosive mixture can be made with the utmost nicety. Both the induction and the exhaust valves are placed horizontally, the former acting automatically, while the latter are actuated by means of cams placed upon the shaft, which also carries the governor. This latter is of the usual centrifugal type, and operates upon the exhaust valves by means of a sliding sleeve, so choking the escape of the products of explosion. An accelerator, conveniently placed at the driver's hand, in turn acts upon this governor, and the speed of the motor can thus be easily varied from 400 to 1,200 revolutions per minute, the normal speed, however, being from 700 to 800. The ignition is electrical, and a special plug constructed by the company itself is employed. The driving gear, that most important item in the construction of an automobile, consists of a combination of belt and cog gear, the actual driving devolving upon the former, while the variation of speed is secured by the employment of the latter. The belt used measures 80 mm. in width, and when running at normal speed travels at the rate of fifteen metres per second. Driving direct from the flywheel of the motor to a pulley keyed on the cross shaft it is, when required, displaced by another pulley, and not by the fork so often employed, and which subjects the belt to side strains. Four speeds are secured by the employment of cog gearing, the changes being effected by means of a lever placed very similarly to the speed change lever on an English Daimler. The car is also provided with a friction clutch, the throwing in or out of gear of which is achieved through the medium of a foot pedal. Of course, the engine is water cooled, the circulation being secured by means of a pump similar in type to the Greindl. The average weight of a complete vehicle fitted with a 7 h.p. engine is 750 kilogrammes, or about 13½ cwt., and the 10 h.p. car brings down the scale at some 50 kilogrammes more. This type of car, fitted either with the 7 h.p. or with the 9 h.p. motor, is represented at the Exhibition by four vehicles. A beautifully-finished Victoria, on a long frame, and with the speed levers placed at the side of the driver, is the first car to attract attention, for it is just the class of vehicle most in demand for town work. Then there is a *charrette*, with seating accommodation for four, the hind seat being enclosed after the style of a *coupé*. A couple of similar cars, but unenclosed, complete the list of larger vehicles, and one then turns to the voituresses, of which there are a couple on the stand. One of these is particularly smart, Kellner's carriage work showing to great advantage. Although very few of these dainty little cars are yet to be seen in use, the demand for them is great, and a large number are in course of construction. The motor has a single cylinder measuring 95 m.m. in diameter, with a stroke of 100, and when running at its normal speed of 800 revolutions it develops rather over 3 h.p. Electric ignition is employed, and the driving gear is, as in the case of the larger vehicle, a combination of belt and cog gearing. The speeds usually fitted are eight and sixteen miles per hour, but the higher speed is increased to some twenty miles per hour by advancing the point of ignition. Needless to say, no reverse gear is fitted, as on a light car of this description it would be a useless complication and encumbrance. The tension of the driving belt is varied by a lever, conveniently placed for the driver, which displaces the position of the rear axle. The car measures 2 metres by 1 metre 50. The price of this little car is only £140, so no wonder that the firm is doing good business with it.

A stand in the vicinity of the Georges Richard exhibit, which always attracts attention, is that of Messrs. Gobron and Brillié, for there are to be found three of the handsomest cars in the hall. The first is a four-seated phaeton, and there is another car of a somewhat similar design. The third is of the *tonneau* or wagonette type, and closely resembles in appearance the vehicle exhibited by the Automobile Association at last year's Richmond Show. The Gobron-Brillié cars are now being also built in Belgium, and it will be remembered that on June 17th last one of these vehicles, mounted by M. Roland, secured first place in its class of the race

at Brussels over a one kilometre course. Its time for the kilometre from a flying start was 58½ sec., equivalent to a speed of 62 kilometres per hour, which is wonderfully good going for a 9 h.p. car. In the near future we shall see a considerable increase in the number of Gobron-Brillié cars, for the firm are now commencing to build them in series. A couple of types of motors are constructed, the one with inclined and the other with vertical cylinders. When built with a single cylinder the former type develops 6 h.p., and weighs with flywheel 110 kilogrammes. It runs at from 400 to 1,400 revolutions per minute. This same type is also built with two cylinders, when it develops 16 h.p. and weighs with flywheel 325 kilogrammes. In this case the speed of the motor is rather less, varying as it does from 300 to 1,100 revolutions per minute. The vertical motor is invariably constructed with two cylinders and develops either 7 or 9 h.p., following the dimensions employed. The less powerful engine turns at from 300 to 1,300 revolutions, while the 9 h.p. revolves at from 300 to 1,200 per minute. The difference in weight is 115 kilogrammes as compared with 170. These vertical motors are also employed for stationary work, such as driving electric plant, ventilation, pumping and agricultural machinery. One of its special features is the carburettor, which is of a quite special construction. This apparatus is perfectly airtight, by which means the makers claim for it entire independence from atmospheric conditions. It is operated upon by a regulator which permits the entry into the cylinders of just so much gas as is required to do the work in hand. A single alteration, readily effected, permits of the motor being driven by ordinary gas, which in itself is a distinctly advantageous feature. Another point, so far as the motor's disposition on an automobile frame is concerned, is the excellent balancing of the engine, which reduces vibration to a minimum, and renders the car more ressemblant to a steam or electric vehicle than to its petrol brethren. There is undoubtedly a big future before the Gobron-Brillié motor and carriage.

Upon the stand of the Decauville Company one finds four of their well-known voituresses, one of them being the identical vehicle which finished third in its class in "Le Tour de France." The newer types of cars are built to hide the motor, and consequently have, to my idea, a much smarter and more finished appearance than their predecessors. As all automobilists know this voiturette there is no need to give any detailed description, and, by way of a complete change, I will pass to a totally different class of vehicle. This is the steam wagon shown by M. Gandon, of 8, Rue Santeuil, Paris, a vehicle which presents some curious features. First of all there is the fact of all four wheels being driven, the medium in each case being an ordinary chain. Then there are the means employed for the easy and rapid heating and feeding of the boiler, both questions of vital importance in the construction of steam vehicles. The engine is of the triple-expansion type and develops twelve horse power, the steam being supplied by a boiler of 10 metres 20 of heating surface, which is stated to produce twice the quantity of steam usually required by the motor. Liquid fuel is used as combustible, and the constructor claims great economy in the running of his car, which, however, as far as the public are concerned, has not yet been submitted to any lengthy official tests.

(To be continued.)

FROM the Scottish Motor Company, Limited, comes a copy of their catalogue, which embraces petrol, steam, and electric motor-cars. Descriptions are given of the De Dion, Vivinus, Benz, and Daimler systems, and the illustrations have evidently been carefully selected. The company, to which reference has already been made in our columns, has made a capital start.

THE proprietor of the New Dorp Beach Hotel, at New Dorp, Staten Island, U.S.A., has purchased a Riker electrical omnibus, by means of which guests arriving either by steamer or railroad are conveyed to the hotel. The omnibus will seat eight inside, four on the cross seat on top, and two with the driver. With the bus running at ten miles an hour the battery has a capacity of twenty-five miles.

The Bordeaux-Perigueux Race.

BY the kindness of our contemporary, *La France Automobile*, we are herewith able to reproduce a number of interesting snapshots taken on the occasion of the recent Bordeaux-Perigueux motor-car race, the results of which were published in our issue of June 9th. It will be remembered that in this race M. Levegh on his high-powered Mors racer covered the distance—318 kilometres—in

4h. 9m. 45sec. The first picture shows M. Lafitte, of Bordeaux, on his 6 h.p. car, the winner of his category. The second picture to the right depicts M. Versein on a new 12 h.p. Schaudel car. In the central illustration we see M. Levegh arriving at Perigueux, while the two lower pictures show respectively M. Jamin, of Mans, and M. Giraud on one of the latest Panhard cars.

A GERMAN MOTOR-OMNIBUS.

WE illustrate herewith a motor-omnibus which has lately been put in service in the German town of Flensburg. The car, which was supplied by the Berlin Motor-fahrzeug und Motorenfabrik of Marienfelde, Berlin, has seating accommodation for ten persons, exclusive of the driver, and can also carry a quantity of luggage on the roof. The vehicle, which is built on the Cannstatt-Daimler system, is fitted with a 6 h.p. motor, capable of working up to 10 h.p. The cooling of the cylinders is effected by a new method, the quantity of water carried amounting to only about 12 litres. The water is cooled by a separate reservoir, containing 2,000 tubes, cold air being aspirated through the tubes by means of a fan. This system of cooling, placed in front of the car, is claimed to have the advantage that, even on the low speed, the water is efficiently

cooled by the fan. Four speeds forward—3, 7, 12, and 18 kilometres per hour—are provided, as also a reverse motion. The bus is fitted with solid-rubber tired wheels and weighs complete about 1½ ton.

WE understand that Mr. J. E. Hutton's four-cylindere Panhard car has been considerably damaged by fire.

MR. A. H. GOWER, of Worthing, has, we hear, ordered a new 6 h.p. double-cylinder car, from the Sports Motor-Car Company.

AT the Westerham hill-climbing competition, the motor-tricycle entered by Mr. F. F. Wellington was an ordinary Phebus-Aster tricycle having a motor of 71 mm.

A MOTOR-CAR service between the tramway terminus at Woodside and Bucksburn, N.B., has been instituted by the Northern Cycle Manufacturing Company, of Aberdeen.

PROPOSALS to establish public services of motor-cars between Oran and Nemonis, and between Oran and Bel-Abbes, Algeria, are at present receiving the consideration of the Oran Chamber of Commerce.

THE proprietors of the *Daily Mail* have, we learn, decided to award their £10 prize in respect of the following vehicles, concerning the performance of which, in the recent 1,000-mile Trial, there were not absolutely complete records:—Locomobile steam carriage, No. 5; Star voiturette, No. 51; M.C.C. Triumph, No. 31; M.C.C. Triumph, No. 32; Lanchester carriage, No. 22; and the Century tandem, No. 39.

STIRLING'S Motor Carriages, Limited, whose head offices are now at 504 to 508, Sauchiehall Street, Glasgow, have just introduced a range of motor-launches. The trials of the first boat (an eighteen-foot one) were made on Saturday last, on the Firth of Clyde, when both the motor and boat surpassed expectations. The motor, which is of the two-cycle type, is extremely simple in construction, and we are informed it never failed once during the very severe trials to which it was submitted. The boats are made in sizes extending from 16 feet to 25 feet, and in view of their relatively low price should meet with a good demand.

STEAM v. ANIMAL POWER FOR HEAVY TRACTION.*

AFTER the trials of motor-vehicles held by the Self-Propelled Traffic Association in May, 1898, the Health Committee of the Corporation of Liverpool decided to obtain a motor-wagon, and ultimately ordered from the Lancashire Steam Motor Company, of Leyland, Lancashire, one similar in design to the vehicle which had been awarded the first prize of £100 offered by the Association.

The vehicle was delivered at the end of January, 1899, and has since been used in connection with the construction of street works for the electric tramways, where it has been found very useful for the quick removal of materials. On account of the varying character of the work, much of it being over very short distances, it has not been found possible to keep very accurate records of the weights of materials conveyed and the distances travelled, but, generally speaking, the load has been from 2½ to 4 tons, and the total daily mileage from 18 to 24, and even 30 miles occasionally. Where the work has been of a regular character the records show that good work has been done; thus, in the week commencing March 6th the motor carried:—

March 6th	3 loads of 4 tons each, 3 miles loaded, 3 miles light.
" 7th	3 " " 4 " " 3 " " 3 " "
" 8th	4 " " 4 " " 3 " " 3 " "
" 9th	4 " " 4 " " 3 " " 3 " "
" 10th	2 " " 4 " " 3 " " 3 " "
" 11th	2 " " 4 " " 3 " " 3 " "

This shows that during the week a net ton-mileage of 216 was obtained, which at £7 per week gives a cost per ton-mile of 7½d.

Again in October, over a somewhat longer distance, a week's work was as follows:—

Oct. 23rd	3 loads of 2½ tons each, 4½ miles loaded, 4½ miles light.
" 24th	3 " " 3½ " " 4½ " " 4½ " "
" 25th	3 " " 3½ " " 4½ " " 4½ " "
" 26th	2 " " 3½ " " 4½ " " 4½ " "
" 27th	2 " " 3½ " " 4½ " " 4½ " "
" 28th	1 " " 3½ " " 4½ " " 4½ " "

This gives a net ton-mileage of 189, which at £7 works out to 8½d.

In a trial made for the purpose of comparing the motor with hired horse-teams on day work on a haulage length of 3 miles, the results were as follows:—

Motor	... 4 loads of 4 tons each, 3 miles light, 3 miles loaded.
Teams (each)	3 " 2 " 3 " 3 " "
This gives for motor	48 net ton-miles at £1 5s. = 6½d. per ton-mile.
" for teams	18 " " £0 10s. = 10d. "

It should, however, be pointed out that where the haulage distance is smaller than 3 miles, the benefit obtained from the greater speed of the motor-vehicle is much reduced, and it appears probable that on distances less than one mile the balance in favour of the motor-vehicle would disappear.

In connection with the use of this motor vehicle in Liverpool, it has been found that the main frames of the vehicle were originally of too light a section to withstand the strains thrown upon them when travelling at a high speed when fully loaded. Many days have been lost owing to lengthened delays in replacing the main frames, and there has also been a further loss of time due to the wheels requiring important repairs. Since these repairs have been executed, the motor has given little trouble, and, taken on the whole, the results have been very satisfactory. The cost for twelve months' working, including wages, maintenance, repairs and £1 per week for depreciation, amount to £243 14s. 8d.

THE Mold Urban District Council has decided to allow the Ashbourne Council's resolution with regard to taxing motor-cars to lie on the table.

* Statement by Mr. John A. Brodie, the City Engineer of Liverpool, on the working of a Leyland motor-wagon, forming an appendix to the paper read by Professor Hele-Shaw before the Institution of Mechanical Engineers.

MOTOR-CARS ON THE CONTINENT.

The Fete des Artistes.

THE Fête des Artistes of Friday last attracted all Paris to Longchamp, and right royally were the visitors entertained, for the committee of organisation had spared neither trouble nor expense to ensure the success of the meeting.

Held under the patronage of Mmes. Sarah Bernhardt, Réjane and Jeanne Granier, as representing the ladies, and MM. Baron de Zuylen, Coquelin Aîné, and Georges Boyer for the men, the success of the fête was always a foregone conclusion. Proceedings commenced at two o'clock with a bicycle sprint race, which was eventually won by the French champion, Jacquelin. This event was succeeded by a couple of bicycle races open to members of the theatrical profession only, the winners being found in M. Stebler, of the Sarah Bernhardt Theatre, among the men, and Mme. Carmen Berthier in the ladies' event. Then came a 15 kilomètre race for professional cyclists with motor-car pacing. The three placed men were Bouhours, Simar, and Bor, and the winner's time was returned as 17 min. 11 secs. At half-past four a great automobile procession commenced, and as every type of vehicle, from the lordly Panhard to the diminutive motor-cycle, was profusely decorated, the scene was strikingly pretty. Some two hundred commemorative banners were distributed, and then, after a lively battle of flowers, the company dispersed, many of them making their way to the Châtelets du Cycle, where from five to eight o'clock a country fête, dance, and concert were held. The Association of Dramatic Artists, for the funds of which this fête is annually organised, will this year undoubtedly benefit largely. Among the English visitors I noted the presence of Messrs. Roger Fuller, Critchley, and Jarrott.

The Jenatzy Case.

It was in March last that M. Jenatzy, the well-known racing automobilist and owner of "La Jamais Contente," was acquitted by the judges of the Ninth Chamber of the Paris Courts, the charge brought against him being one of homicide by imprudence. Now, Monsieur Santié, the husband of the lady who met with her death in the accident of January 21st last, and who, at the first hearing, claimed £720 damages from Monsieur Jenatzy, has appealed against the judgment, and last week the affair was before the judges of the Appeal Court. After counsel for both parties had pleaded, the further hearing of the case was postponed for a week.

A Motor-cycle Adventure.

FROM Levallois, a suburb of Paris, comes one of those extraordinary stories which every now and again send a thrill through the whole automobile community and cause enthusiasts to exclaim, "It is wonderful what a motor can do. Why, I remember," etc., etc. As related, more or less, by M. Georges Prade, of the *Vélo*, it would appear that on Saturday last a youthful mechanic, mounted on a motor-cycle, was passing along the Quai Michelet at Levallois when his machine became peevish and disagreeable. Dismounting in haste to ascertain the why and wherefore of this display of temper, our young engineer omitted to turn his "poignée," and so cut off the electric current, with the result that, while busily engaged in inducing the trembler to tremble and in coaxing the other things into good temper, he was horrified to see the machine leap forward with the evident intention of taking to flight. But the young man was full of courage and determination, and his conduct under the trying circumstances is deserving of all praise. Without a second's hesitation he sprang at the head of that raging machine, and grasping it securely with one hand, he spoke to it gently but firmly with the other, as Pat would say. Even this heroic conduct proved of no avail for, drawing in a deep breath of gas and air through its wide open induction valve, the infuriated machine hurled the unfortunate youth to the ground and with a snort of triumph passed over his prostrate body.

This disgraceful conduct met, however, with its just reward, for when the battered engineer cautiously raised his head in anticipation of a further attack, he perceived his unhappy machine busily engaged in sealing the pavement preparatory to plunging headlong into the Seine. A splash, a fizzle, and only the widening ripples on the river's placid bosom served momentarily to indicate the grave of a foolish motor-cycle. It is said that only by main force were the passers-by able to restrain the mechanic from rejoining his machine, for he had cherished a grand affection for it and was inconsolable at its sad fate. Later, however, a great joy was accorded him, for a band of sympathetic anglers set to work and for the first time in their lives fished something from the waters of the Seine. Such is the true and unexaggerated history which hails from Levallois. Next please!

The Bourgerie Motor-Bicycle.

A NEW motor-bicycle has lately been introduced by M. J. Bourgerie, of Paris. As will be seen from the accompanying illustration the frame of the machine differs only from the ordinary safety in having longer chain stays and a double set of back forks. The motor is supported on the chain stays under the saddle and just behind the bottom bracket. It is of the air-cooled type, and at 1,200 revolutions per minute is said

to develop just over 1 h.p. The motor drives the rear wheel by means of a strap working on a pulley attached to one side of the wheel. Two speeds are available by means of clutches on the motor shaft. A simple form of carburettor is adopted. Pedals and chain gear are provided as usual, the exhaust box being located underneath the bottom bracket. The machine which, it is stated, can attain a speed of thirty miles per hour, weighs complete about 83 lbs.

Next Year's Nice Meeting.

THE Automobile Club of Nice evidently believe in issuing their announcements in good time, for already the dates and general outlines of next year's spring meeting have been made public. The programme of the "week" will be as follows:—March 24, Sunday: At two o'clock an automobile *corso* will be held. March 25th, Monday: Automobile race of from 450 to 550 kilomètres in length on the route from Nice to Avignon. This *course* will be decided in a single stage. On the same day the tourists will again do battle over the Nice-Druguignan-Nice route. Some £400 worth of prizes, medals, etc., will be contested for in these two events. March 26th, Tuesday: Exhibition of competing vehicles. March 27th, Wednesday: Exhibition of competing vehicles, followed in the evening by a banquet offered by the Automobile Club of Nice to the winners and to the foreign automobilists. March 28th, Thursday: Mile and kilomètre race. March 29th, Friday: Hill-climbing contest on La Turbie. Automobilists visiting Nice will find the condition of several roads greatly improved, and that petrol can now be obtained at many places where formerly none was kept. These changes are mainly due to Monsieur Gondoin, the President of the "A.C.N.," who is always actively engaged in furthering the cause of automobilism.

Magnalium Adopted in German Daimler Vehicles.

M. PAUL MEYAN, writing to *Le France Automobile* from Cannstatt, reports that the Daimler Motorwagen Gesellschaft has definitely determined to adopt magnalium in the construction of both motors and vehicle frames. The composition and properties of this alloy may briefly be summarised as follows:—Composition, magnesium, 25 per cent.; aluminium, 75 per cent.; specific gravity slightly less than that of pure aluminium; tensile strength somewhat over 5,000 lb. per square inch. It is readily cast, and can be machined without difficulty. In general physical characteristics it resembles hard bronze. M. Meyan, describing it, adds that it can be brazed and soldered, and also punched and stamped in the sheet form. The comparative strength of magnalium and aluminium is indicated by the fact that where two similar bars were gripped in a vice, while the aluminium bar was broken at the first blow of a hammer, some ten hard blows were necessary to break the magnalium bar. In connection with the intended use of the new alloy, the Daimler Gesellschaft has projected a number of radical improvements. The chief of these is a motor of novel design, built almost wholly of magnalium, and having mechanically-opened inlet valves, and an improved radiator, which will require the carrying of only six quarts of water for a 16 h.p. motor. Other features will be the use of an absolutely irreversible steering gear, a new brake mechanism, and a lightening of speed gears and other parts, so that a 16 h.p. vehicle will weigh only 900 kilos., or less than 2,000 lb.

FURIOUS DRIVING CASES.

AT Wolverhampton, last week, Mr. T. F. Turvey, of Longford, Middlesex, was charged with driving a motor-car along the Tettenhall Road, Wolverhampton, at an unreasonable rate. It was stated that his car was proceeding at a rate of sixteen miles an hour. He was fined 40s. and the costs.

MR. FRANK H. BUTLER was summoned before the Guildford County Bench on Saturday for furiously driving a motor-car by the Green Man, London Road, Worplesdon, on June 23rd. Police-constable Brooks stated that the motor was going about eighteen to twenty miles an hour, and was driven by defendant. Witness called out, and defendant stopped in about 20 yds. Defendant gave him his card, and said, "You are not obliged to do this, let me give you something for yourself." Mr. Butler also said, "I know I am going over the rate; I want to make haste home." Arthur Cox, electrical engineer, living at Send, said that on seeing a motor-car going along the road, and not on its right side, he blew a police whistle to warn the people on the road, as he thought that the driver had lost control of the car. He could scarcely see the motor for the dust that it was making in consequence of going so fast. Mr. Staplee Firth, of London, was for the defence, and called attention to the section under which the summons was taken, which was in effect that a motor-car should not travel beyond a reasonable and proper rate, having regard to the traffic on the highway. He contended that there was no evidence before the Court that the speed, whatever it was, was improper, having regard to the traffic on the highway. Mr. Butler was a most experienced and careful driver and he would tell them that the car was going under ten miles an hour. Had it been going at the speed alleged, and been pulled up in 20 yards, the car would have been smashed, and the occupants thrown out and in all probability killed. A motor-car, it was well known, always seemed to be going very much faster than it really was. Defendant gave evidence bearing out the foregoing statement, and denied that he admitted to the constable that he was "going over the rate." He did not offer the constable half-a-crown to bribe him, though he often gave constables a tip. This constable did not accept the money, but he offered it him because he did not want to be kept waiting about. Robert William Buttemer, living at St. Mary's, Godalming, also gave evidence on behalf of the defence. If the car was going at twenty miles an hour it would have been impossible to stop it at twenty yards. The Bench having privately consulted, the chairman said: We have considered the case very carefully, and have come to the decision that the defendant was driving to the great danger of the public. He will be fined £5. Mr. Firth: I ask your Worship formally for a special case to be stated. The Clerk: On what ground? Mr. Firth: I'll send that in my notice. Mr. Butler (to Mr. Firth): You had better pay the fine, and I shall appeal. I never heard such a preposterous charge.

DRIVING TO THE COMMON DANGER.

AT Lowestoft last week Mr. Reginald Lawrence was charged with driving a motor-car to the common danger on the Wellington Esplanade, Lowestoft, on the 27th ult. Mr. G. J. Cook prosecuted, and Mr. Staplee Firth, solicitor, of London, defended.

Sergeant Botwright said he was on duty in Claremont Road when he

saw the defendant, who was driving down the Wellington Esplanade towards the bridge. He should think the speed was fourteen miles an hour. He did not hear any bell or trumpet as the car passed the corner, and if anybody had been crossing the road defendant must have driven over them. Cross-examined, he did not know that the car could be stopped in its own length while going at twelve miles an hour, but it would be necessary to stop at once.

Mr. Firth said in order to support the charge of "common danger," there must be absolute evidence of somebody being injured. There was no evidence of that kind. His client was not summoned for his speed, but for driving to the common danger, and they must keep to the summons. He asked them to dismiss the charge, because there was no evidence of anybody being in danger.

After a lengthy consultation, the magistrates decided to hear the evidence. Defendant said he was an engineer by profession, and had driven motor-cars in the district since November last. He had never had an accident. Last year he drove several thousand miles in France, and had driven through the heavy traffic in London, and had never even touched any other vehicle. For safety of passengers and facility of control he would rather drive a motor-car than horses. On this occasion he should say he was driving at eight miles an hour. The case was dismissed.

AN ACCIDENTAL DEATH.

ON Monday, at Kensington, Mr. Draw held an inquest on the body of Mr. Lewis Perry, of 4, Pembroke Villas, W.—The evidence showed that the deceased was crossing the road at Pembroke Place, when he was knocked down by a motor-car driven by Mr. F. Hennig, of Blenheim Crescent. Witnesses said it was a pure accident, and that the deceased seemed to lose himself after reaching the side in safety and ran into the car again. The jury returned a verdict of "Accidental death," and asked the coroner to call the attention of the Commissioner of Police to the fact that they considered the rate of speed sanctioned for motor-cars was too great, especially in London.

ACTION OVER A MOTOR COMPANY.

MR. CROWDEN, engineer, of Leamington, brought an action at Warwick last week to recover £50 from Mr. Tolch, engineer, of Fullam, being half of a certain bill of costs for floating a motor company. Mr. Masser (Coventry), appeared for the plaintiff, and Mr. H. W. Williams (Fullam) for the defendant. The plaintiff's case was that the defendant advertised a German motor patent for sale. The parties thereupon agreed to float a company, registered as the Road-railing Tractor and Motor Syndicate, Limited. They were to share the profits and losses, and the sum of £100, the subject of this action, was incurred in legal costs to Mr. Maddocks, solicitor, Coventry, in the formation of the company. Subsequently the defendant repudiated the agreement, and said that it had been abrogated by mutual consent. His Honour held otherwise, and judgment was given by consent for £48 without costs to cover all claims.

CAB v. MOTOR-CAR.

JOSEPH STIBBARDS, cab proprietor, of Wilson's Yard, Highbury, has sued the Motor Car Company, Shaftesbury Avenue, W.C., for £50 damages for injury to a horse and other loss caused by the negligence of the defendants' servants. Mr. Salter, for the plaintiff, said a hansom cab belonging to the plaintiff was going along at an ordinary pace in New Oxford Street, and immediately in front was a motor-car belonging to the Motor Car Company under the control of quite a young man, and he asked the jury to come to the conclusion that the driver was too inexperienced to have charge of the car. The motor-car without any warning suddenly stopped dead, and whether it was intentional or not could not be said. The result was that a severe wound was inflicted on the horse's leg, and another horse had to be sent for.

Evidence having been called in support of this statement, the Judge entered a verdict for £46 12s.

MR. F. F. WELLINGTON'S latest list of motor-cars and cycles for sale comprises no less than 124 vehicles.

THE Master of the Rolls (Lord Alverstone) has had delivered to him a 12 h.p. Panhard. It is painted in khaki colour, has a glass screen in front, and has a kind of wagonette body to seat eight people.

AT Falkirk a little girl has, this week, been run over by a motor-car; at Weston-super-Mare a car belonging to the Bristol Motor-Car Company has collided with a cyclist; and at Sheffield the manager of the Dragonfly Cycle Company has been overturned while riding a motor-quadracycle. This list of accidents in one week shows that automobilism is not the dangerous and killing pastime some opponents imagine.

THE Motor-Car Journal.

Vol. II.]

LONDON, SATURDAY, JULY 21, 1900.

[No. 72.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

WITH characteristic enthusiasm the Prince of Wales seems bent on thoroughly enjoying the pleasures of automobilism, and the other day was seen on the Hon. J. Scott Montagu's 12 h.p. Daimler car. Mr. Montagu was driving His Royal Highness through some of the fine scenery of the New Forest, which is, just now, looking at its best. In these days of heated roads and scorching sun the beautiful trees of the New Forest offer a welcome shade to those who want to revel in the beauties of the country without bearing too

much of the heat of the day.

Motorists at Ranelagh.

It was a fashionable gathering that assembled at the Ranelagh Club on Saturday to witness the first automobile gymkhana held at that rendezvous of Society. In the morning members of the club owning horses had had their animals educated in maintaining a respectful attitude in the presence of automobiles, and in the afternoon the scene was a brilliant one indeed. Hundreds of beautiful woman splendidly attired were there to see the sports, and from a social point of view no function could have been more successful. The course along which the races took place was 1,570 yards long. Two of the events were run along the straight, and only in one of the remaining four did the competitors make more than a single circuit of the course. Altogether twenty-one competitors had entered and considerable interest was manifested in the contests.

Results of the Races.

In the handicap bending race Captain Langrishe on a 8-h.p. Peugeot, Mr. Cecil Grimshaw on a 6-h.p. Daimler, and Mr. E. Campbell Muir on a Locomobile won heats, and the Hon. C. S. Rolls ran a bye on his 12-h.p. Panhard. In the final Mr. Grimshaw defeated Mr. Rolls, who was rather heavily handicapped. In the contest starting from "cold," Captain Langrishe, with 75 yards start, was first, the Hon. C. S. Rolls, who started from scratch, obtaining the second place. The ladies' race was a fine one, and the finish between Mrs. Kennard on her 3-h.p. De Dion voiturette and Miss Weblyn on a 6-h.p. Parisian Daimler, particularly good, the latter securing a win. In the motor-tricycle race, in the course of which coats and waistcoats had to be doffed and hung on pegs, the Hon. C. S. Rolls would probably have won had not his machine bucked at the beginning of the third lap and thrown him on his back. He had, in consequence, to again be satisfied with a second place, the winner of the first place being Captain Langrishe. Mr. R. E. Phillips, on his "Petit Duc," won the first prize, defeating Mr. Campbell Muir on his Locomobile in the final. The last event was an obstacle race, and in the end Mr. Phillips (510 yards start) won, with Mr. Rolls next home, followed by Mr. Grimshaw. Mr. Rolls was, however, disqualified, and the prize went to Mr. Grimshaw.

854 Miles in Three Days.

It will interest British automobilists -- and those of other countries as well -- to know that the Hon. C. S. Rolls and Mr. S. F. Edge will take part in the Paris-Toulouse-Paris race organised in connection with the Paris Exhibition. They will drive the 16 h.p. Napier car, and the stage to be covered on the 25th instant is 427 miles, on the next day 190 miles will have to be travelled, and on the third day 237 miles -- 854 miles in all. On the concluding days of July and the first two of August the competing vehicles will be exhibited at Vincennes, and the criticisms of our French *confrères* on the Napier car will be regarded with considerable interest. The English competitors will have some excellent rivals on the road, among the entrants being such champions as MM. R. de Knyff, Charron, Girardot, Voigt, Gilles Hourgières, Levegh, Degrais, Et. Giraud, Jenatzy, and Lefebvre.

Motoring in Ireland.

ON another page we publish an account of the motor-car meet in Ireland, which was evidently a great success. In the evening of the run the visitors were entertained to dinner in the Lakeside Hotel, Killaloe, by the directors of the Shannon Development Syndicate. Mr. D. J. Wilson presided, and, in the course of his remarks, referred to the connection between the Tourist Syndicate and motoring. The Shannon Development Syndicate was concerned not only with the tourist traffic of the Shannon but that of the rest of Ireland also, and as motoring was likely to be of the greatest aid to the Irish tourist traffic generally, it was only natural that the syndicate should be greatly interested in its development. Mr. R. J. Mecredy referred to the usefulness of the motor-car for the conveyance of goods in country districts not served by railways. Goods and merchandise could be carried by the motor-cars at a much quicker and cheaper rate than by the present system in most parts of Ireland. He referred incidentally to the experiment carried out by Messrs. Guinness in Dublin for the delivery of their porter in the city and its vicinity, and he said the firm was so satisfied with their experience of the motor that they had given an order for three additional cars.

The Automobile Congress at Paris.

ON the morning of Monday, July 9th, the first meeting of the Congress of Automobilmism was held in the Palais des Congrès at the Paris Exhibition, M. Forestier, engineer-in-chief of roads and bridges, occupying the presidential chair. He was supported by M. Amedée Bollée père and M. le Comte de Chasseloup-Laubat, while the company present mustered some 150 strong. At this initial meeting the principal business transacted was the election of officers and the formation of the various sections. The officers of the Congress were:--President, M. Forestier; vice-presidents, Sir David Salomons, Comte de Dion, and M. Ruys Orban; secretaries, Comte de Chasseloup-Laubat, Jeantaud, Bochet, Varennes, and Collin. The sections were presided over by the following gentlemen:--1. Steam, explosive, and various motors, M. Amedée Bollée; 2. Electric motors, M. Monmergué; 3. Transmissions, frames, and carriage

buildings, Commandant Maugin; 4. Traction force, M. Forestier; 5. Historical, economical, and international questions, M. Baillif. On the afternoon of Monday a move was made to the Automobile Club, where all subsequent meetings were held. The first meeting there was devoted to a discussion on steam and explosive engines, and the second, held on the morning of the 10th inst., was confined to the electric motor, M. Hospitalier being the principal speaker on this subject. At the afternoon *séance* M. Gaillardet presented a paper on transmissions; M. Crouan on pneumatic transmission; M. Amedée Bollée on frame construction; M. Jeantaud on frames and their suspension; M. Bochet on brakes; Capitaine Ferrus on brakes and axles; and M. Michelin on tires. The following morning M. Forestier dealt at length with traction matters, and the afternoon M. Baillif discussed the various phases of the customs duty. M. Sauvage also presented a paper on the unification of gauges. On Thursday morning the members of the Congress visited the works of M. Lemoine and MM. Panhard and Levassor, while in the afternoon the factories of M. Clément and MM. De Dion and Bouton were inspected. Friday was devoted to a visit to the Vincennes exhibition, and on Saturday a tour was made of the Automobile Section at the Champ de Mars. The Congress closed with a banquet given at the Club on Sunday night.

An Example for Electric Tramway Managers.

ONE of the latest uses to which the automobile has been put is in electric tramway work. The Metropolitan R. R. Co., of Washington, U.S.A., has just had an emergency or repair wagon built for service on its extension lines. The doing away with horses for traction purposes has made the keeping of two or more horses by electric tramway companies for special duty both expensive and inconvenient. The automobile is therefore able to meet every requirement, and when not in use the storage space is small and expense of maintenance nothing. This wagon, which was built by the Riker Company, of Elizabethport, N.J., will carry fifteen or twenty men and their tools. It is provided with an A-ladder, so that repairs to the overhead conductor can be quickly made. The complete vehicle weighs about three and a half tons. A towing device for pulling cars on to the track or taking a disabled car to the repair shop is also provided. The motive power is an electric storage battery, which is good for twenty-five miles, at fourteen miles per hour. Now that electric tramways are becoming more common in England, managers of the lines may well keep the example set by the American company in mind.

A New Map.

DESCRIBING with wonderful accuracy 28,000 miles of road and showing 1,700 dangerous hills in this country the Complete Safety Cycling Map of England, published by Messrs. Gall and Inglis, will be found useful by all automobilists. From this map, which is arranged on a scale of fifteen miles to an inch, the tourist can ascertain the best roads from point to point, while the fact that the roads are printed in different colours will help him to select the fastest and most direct routes. Blue markings indicate the roads to avoid, and the gradation of the colours indicates the superiority or inferiority of the roads in that particular district. Uniform in size with the Contour road map, so far as the cover is concerned, the map should become as popular as the other publications of the firm.

Tours.

WE hear that several automobilists have been spending their holidays touring on their cars through some favourite English counties. Not only are such trips to be recommended for their invigorating qualifications but they will do much to serve the interests of the movement generally. From the West of England papers it is clear that a stylish motor-car which has been touring through Devon and Cornwall has attracted much attention and its movements have been chronicled

in the local journals. We shall be glad to hear from readers on tour by motor-car.

Carriage Builders and Automobilmism.

WE hear that in the United States the leading carriage builders are more alive to the possibilities of the motor-vehicle than are the majority of those of this country. All over the States the chief carriage builders are installing plants for the production of motor-cars, and in the combination of engineer and carriage builder is a very hopeful prospect, for, the latter will consider the appearances of the vehicles to a far greater degree than the engineer is likely to do, and thus the eye of the public should be readily attracted, and although appearances are not everything they constitute an important factor in commercial success at the present day.

The Next Exhibition.

RECOGNISING the success of the last motor-car exhibition at the Agricultural Hall, Islington, several firms have already booked space for the next display of motor-vehicles, which will take place at that convenient centre from May 4th to May 11th next year. This annual event is now so well established, not only so far as the trade is concerned but also in the mind of the public, that there is no need to dilate upon its leading features. Suffice it now to say that the date is fixed, and firms anxious to secure the best positions should make early application.

A New Suggestion.

A GENTLEMAN has been writing to the papers suggesting that a club should be started in which twenty members should pay £10. Then a car would be bought and lent to each member for a day in rotation. However simple this may be it is hardly likely to find adoption. The pleasures of complete ownership are too fascinating for a man who is really an enthusiastic motorist to be satisfied with the probability of a ride once in three weeks—whether the weather be wet or dry.

A Trip from Liverpool.

THE second meet and run of the Liverpool Self-Propelled Traffic Association for the present season takes place on Saturday, the 28th inst. About noon the party will start from St. George's Landing Stage for Seacombe. Following the tram lines through Wallasey village luncheon will be taken at the Leasowe Castle Hotel. At three o'clock departure will be made for Hooton Hall, *via* Moreton, Hoylake, West Kirby, Caldy, Thursleston, Glegg's Arms, and Eastom. At the Hooton Park Club tea will be provided, and after seeing a polo match there the party will return, each member at his or her own convenience.

The French Military Authorities Show the Way.

AN extensive use of motor-cars and cycles is contemplated in connection with the French military manoeuvres, which are to be held in the neighbourhood of Chartres from the 10th to the 20th September next. A number of motor-cycles are to be employed for despatch purposes, while four steam wagons and four petrol vans are to be set apart for the transport service. Not only so, but four high-powered cars have been obtained for the use of the generals, who will direct the operations, not on horseback, as usual, but from the comfortable fixed seat of the more useful automobile. We can imagine that when this item of news penetrates into the dark official recesses of our benighted and red-taped War Office there will be a flood of questioning from some of the junior officers whose notion of motor-cars has been obtained in Hyde Park as to whether it is possible for a military man to so disregard his horse as to condescend to adopt something new. The French War

Office has not stood in very great dignity in recent months, but its practical investigation of the merits of the motor-car shows that disturbing influences have not wholly upset its common sense. Apparently some great upheaval—an earthquake perhaps—in Pall Mall might do something to break through the thick-coated ignorance that closes our own War Office to new ideas, and, we might add, the country's interests. France is not alone in its attention to the practical side of automobilism in connection with military matters. We have in former issues shown how Germany does not mean to be left behind, and that even Italy can set us an example in having already adopted steam motor-wagons for transport purposes in its army. It is to be feared that, as usual, our War Office authorities will wake up to the advantages of motor-cars when all the other Powers have had some years' experience of the same, just as has been the case with regard to military cycles. Or perhaps the interests of our War Office in the question may be quickened should the Boxers make inquiries on the subject before Pall Mall discovers that there is a war in China.

country with a fair prospect of success, although the need is not, perhaps, so great as in the United States, where good roads in secluded country places are less familiar than in England. Still, the idea might be developed into a useful and successful enterprise.

A Warning Ignored.

SEVERAL times have we warned cyclists against the too prevalent practice of riding behind motor-cars. Some protection from the wind is thereby secured, but the risk run by venturesome cyclists is great indeed, and a Kennington cyclist was seriously injured on Sunday in consequence. He was following a car to town, and when at Crawley the vehicle was brought to a sudden stop, with the result that the cyclist was thrown to the ground, and sustained serious brain injury. The practice is too dangerous to be adopted by any cyclist of ordinary intelligence, and this sad occurrence should emphasise the warning so repeatedly given.

AT STRAWBERRY HILL HOUSE—THE LADIES UP. (See last issue.)

Photo by]

[Argent Archer, Kensington.

Motor-Cars and Showmen.

SOME time ago we chronicled the tour of a cinematograph entertainment through the northern counties, a motor-car being employed to convey the apparatus and impedimenta. At some seaside towns the automobile is now to be seen in the service of public entertainers, and at Blackpool a phrenologist is combining the investigation of bumps with demonstrations of the smooth running of his car in that locality. Visitors can go on an excursion and have their phrenological examination while they ride—a saving of time that might be considered by hairdressers and others with whom the modern man is compelled to waste many precious minutes every week.

Automobile Training Schools.

IN one or two American cities and in foreign towns are to be found automobile training schools. Places where the novice can be instructed in the handling of an automobile and can practise until sufficiently skilled to be trusted on the public streets are certainly desirable. A thoroughfare, and particularly a prominent one, is hardly the place for a beginner to take his first lesson, however skilful his instructor may be. The time is undoubtedly coming when such schools may be started in this

A Jockey as Automobilist.

OFTEN have we pointed out that the owners of motor-cars include many famous owners of horses, and that the love of the horse is not necessarily opposed to admiration of the automobile. Now we can go a little further, for it is reported that Tod Sloan, the jockey, has purchased the racing machine of M. Charron, which took part in the Nice-Pordeaux contest. The price is said to have been 55,000 francs. If Sloan and jockeys take to motoring, some of the present automobilists may have to look to their laurels.

Are Motor-Cycles Carriages?

ACCORDING to *Hearth and Home*, the Wood Green magistrates have decided that a motor-tricycle is a carriage, and that an Inland Revenue licence must be taken out. The defendant pleaded that a motor-tricycle was not self-propelling, as it had to be assisted by pedalling; but this view did not prevail with the Wood Green dignitaries, who ordered him to obtain forthwith a 15s. licence. The Inland Revenue authorities prosecuted, and urged that the motor-tricycle came within the provisions of the Act as a carriage.

Labelling Horses.

IN reply to the proposal that motor-vehicles should be conspicuously numbered, we would make a suggestion that horses of known vicious habits should be labelled as such. We will not say whether the idea is given seriously, but it does seem that those who would label motor-vehicles are looking at the matter from the wrong point of view. The ways of the motor-car are known; it will go wherever it is steered, and can be guaranteed to proceed in a regular line; but there are horses of vicious temperaments that have no such regularity of movement, and which approach unfamiliar objects in a state of greater excitement. Surely such animals ought to be distinguished in some way or other, for they form a distinct public danger. At any rate the notion should be made known to advocates of numbering motor-vehicles.

Taxing Motor-Cars.

EVERY post brings us news of more resolutions by local councils on the taxation of motor-vehicles and cycles. Many are the reasons urged, but most are uniformly distant from actual knowledge of the subject. Perhaps Mr. W. S. Hodgson, the chairman of the Fylde Rural District Council, was nearest the mark when he said to pass such a resolution would be as reasonable as to tax anyone who walked on the highway in shoes and stockings. The *Burton Mail* refers to the proposal to tax motor-cars as "arrant ignorance." Evidently motorists need not despair, for Mr. J. Bigwood, M.P., has written that, "from my experience of the House of Commons I plainly see that he would be a bold and unsuccessful Chancellor of the Exchequer who would attempt to draw within his Budget net the imposition of taxation upon any form of motor."

De Dion Motors.

A FINELY illustrated catalogue comes from the De Dion-Bouton British and Colonial Syndicate, Limited. It is concerned with the De Dion-Bouton motor-carriages, motor-cycles, motors, etc., and deals very lucidly with the salient features of these inventions. Particularly useful are the practical directions for using the company's motor-tricycle, the principal causes of non-working and the methods of remedy being adequately treated. Attention is also directed to the De Dion detachable trailing carrier, which can be fixed behind the ordinary motor-tricycle in two minutes, and is extensively adopted in France for business purposes. In the section relating to the parts of the De Dion-Bouton motors, particulars relating to every part are given, and the work is completed with a practical guide for using the De Dion voiturette. A description of the carriage and of the motor is followed by illustrated accounts of the carburettor, the electric ignition, and the speed-changing gear. Altogether the catalogue is considerably above the average of such publications.

A Trip in the North.

A FEW days ago Mr. T. R. B. Elliot left Abbottrule, Kelso, in his motor-car for a tour in England. The first day's run was to Rokeby Park, Barnard Castle, Yorkshire, via the Carter (crossed at a level of 1,400ft.), Newcastle, Durham, and Bishop Auckland, the distance being 102 miles, which was comfortably covered between 9 a.m. and 8 p.m. (with an hour's rest for lunch). Another day's run of 90 miles, via Boroughbridge, York, and Malton, brought the car to Filey, on the Yorkshire coast, from which some minor runs to Scarborough and Bridlington were made. The return journey was by the same route, and the average legal maximum of 12 miles an hour was fully maintained, except in crossing the Cheviots. The car gave no trouble throughout, and at one point was driven five hours without a stop. The only incident of the trip was the running over and killing of a chicken in Yorkshire. The car at times carried four passengers.

Automobiles in South Africa.

WHILE the advancing popularity of the motor-car excites so much suspicion among a certain section of the English community, it is apparently accepted without grumbling in distant parts of the Empire. For example, the automobile has for some time past been a common object in Cape Town, and although the *Cape Register* does not regard the motor-tricycle as lending an attraction to the new century, it recognises "the favour with which motor-cycles seem to be regarded everywhere. The malicious opposition which cyclists had to encounter at the hands of the farmers and country people has not been extended to the new vehicles, evidently a sign of the age, for even the back-veldt Boer has become accustomed to the horse's mechanical rival."

Advancing Prices.

ADVANCING prices appear to be the order of the day in the motor-car industry. The Daimler Motor Company have announced that as from Monday last, the 16th inst., the prices of their 1900 type motors and frames (Model "A" and Model "C") have been raised by 12½ per cent. and the ordinary type (Model "B") by 7½ per cent. The recently-formed Sports Motor-Car Company, Limited, also inform us that owing to the demand for the Mayfair voiturette they will be obliged to advance the prices of the same ten guineas on and after August 1st next. On the other hand the Motor Manufacturing Company, Limited, call attention to the fact that they have not advanced the prices of their motors or vehicles.

Bicyclists as Parasites.

EVERY automobilist knows the silly way in which some bicyclists follow motor-carriages without recognising the danger of the practice. Should the vehicle have to stop suddenly and the cyclist be thrown, the latter grumbles as though he were the victim of some ill-will. The nuisance is as great in the United States as in this country, and the Washington papers report that the persistent dogging of automobiles in that city by unmannerly bicycle riders has become a pronounced nuisance, several wheelmen often following a single carriage, suiting their pace to that of the carriage, and refusing to leave it. One journal records the intention of a recent steam-carriage purchaser to fit his vehicle with a multiple blow-off pointing backward, "which would at least keep the parasites at a somewhat respectful distance." Users of electric or petrol carriages, however, would have to find some other defence, and a shotgun loaded with coarse salt is suggested as a deterrent. The mounted police have been instructed to give attention to the matter.

A PUBLIC motor-vehicle service is about to be started between Mansfield and Shelby, O. A motor stage line is also projected between Elizabeth and Morristown, N. J., U.S.A.

MR. JAMES W. THORNE, a student of Princeton University, U.S.A., is said to have started on a tour across America in a specially-constructed motor-wagon. The latter is a long, closed affair with several compartments, provided with cooking utensils, beds for three persons and a storage room for guns, fishing tackle, and cameras.

UNDER the direction of Mr. G. E. Schwarzkoff, editor of the *Automobile Magazine* of New York, an automobile exhibition will be held in connection with the Greater Inter-State Fair at Trenton in September. There will also be automobile races on the driving track for electric, petrol, and steam vehicles.

MR. C. J. FIELD, the vice-president and general manager of the recently-formed De Dion-Bouton "Motorette" Co., of New York, has just returned to America from a trip to Europe. He has closed arrangements to control the De Dion-Bouton and Co.'s patents in the United States, and the "Motorette" Co. will commence at once the manufacture of motor-vehicles of the De Dion type.

THE IRISH MOTOR TOUR.

(From Our Own Correspondent.)

GOOD fortune and weather attended the great motor journey which the Shannon Development Syndicate, with commendable enterprise, organised last week to convey guests and Press representatives to a new tourist hotel at the beautiful town of Killaloe on the Shannon. The project had been widely advertised, and certainly achieved, in no uncertain way, the dual object of booming the new hotel and wakening up the country to the possibilities of motor traffic. Nine cars made an informal start from different parts of Dublin at an early hour on the morning of July 14th, it having been deemed wise that no regular meet should be held, and that the cars should not attempt any racing. It was purely a pleasure trip, the great essential aimed at being that the guests should all be safely conveyed to their destination. The eyes of the entire country were on the performance, and any hitch would have been fatal.

The starters were: Daimler car (Mr. Mecredy), Daimler car (Dr. Colohan), Daimler car (Mr. Tooms), Marshall car (Mr. F. Hutton), Marshall car (Mr. Peacocke), Gladiator voiturette (Mr. H. Hutton), Ariel quad (Mr. McDonald), Ariel tricycle (Mr. J. W. Stocks), and a De Dion (Mr. Fleming). At first rather gloomy weather prevailed, and long upgrades and a stiff head wind hindered the heavily-loaded cars from making top speeds. The powerfully-engined Daimlers showed to advantage here as they very successfully contended against the adverse circumstances. Especially fine was the running of Dr. Colohan's car, a Daimler, in which Messrs. Hutton, Sons, and Co., of Dublin, have made several important alterations, such, for instance, as optional electric firing in addition to the ordinary tube ignition. This car, which was on its trial run, behaved splendidly, as did the other two vehicles of the same make. Very noticeable, too, was the smooth running of the Marshall car; indeed, all the vehicles did well.

The route selected lay via Naas, Newbridge, Kildare, Maryborough, Roscrea, Nenagh to Killaloe, a distance of 110 miles. At every town, village, and hamlet along this stretch crowds were posted eagerly awaiting our arrival, and their enthusiasm was truly Irish. Nothing would dissuade them from the belief that the affair was a fierce race; and the varying quality of the remarks, from applause for the likely winner to the kindly commiseration for those who were last in the "race" was intensely amusing to observe. We were indeed a long-drawn-out line, and each set his pace without any attempt at closing up or forcing the cars to competitive tests. The De Dion had an easy start and kept up a rattling pace all through with no delays. Halts for meals were made by most of the riders on the other cars, whilst at the end of the first fifty miles the Gladiator, Marshall, and one Daimler waited for over two hours till some expected passengers arrived by rail.

From the scenic point of view the journey was most fascinating. First, we had miles of melancholy, wind-swept boglands alternating with green spots of pasture or meadow land. Gradually the country became richer and more varied, till past mid-distance we reached Tipperary and plunged into sweetly pretty woodland scenery diversified by many green pastures and fertile tracts, whilst hemming us in were the grand ranges of the Devil's Bit mountains. Under glorious sunlight everything looked delightfully fresh, and the sensation of dashing through the balmy fragrant air with lovely prospects ever before the eye made the trip one of unalloyed pleasure.

Killaloe was reached by the De Dion about 2.45, and Mr. Stock's Ariel followed soon after, he having made a late start. Then Mr. Mecredy's and Dr. Colohan's Daimlers swung in, followed an hour later by the third of that breed. This car had a very smart run from Maryborough, carrying a heavy load over the sixty miles in less than 3½ hours without a stoppage. By dinner time all the cars had arrived, the only mishap occurring being an accident to the tire of Mr. McDonald's quad., which delayed him somewhat. Special trains had brought an immense crowd of people to Killaloe, and that little town, which is now some 1,200 years old, has had few more exciting times than on this eventful day when the first

motor-cars plunged into its sleepy hollow. Trial trips were given on the various cars to many influential men from Limerick and other districts, and the greatest interest was evinced in the cars and the marvels they performed.

On Sunday seven of the vehicles returned to Dublin, while Mr. Mecredy's and Dr. Colohan's Daimlers started on an 800-mile trip down South. We reached Listowel on Sunday evening, after a sixty-seven mile run. Portion of this lies along the shores of the noble Shannon estuary, here several miles wide. The scenery

SOME OF THE VEHICLES IN THE RUN.
DAIMLER CAR (DR. COLOHAN); A DE DION VOITURETTE; AND A DAIMLER CAR (MR. R. J. MECREDY).

was simply superb, and we enjoyed one of the finest runs I have ever experienced.

CAN any of our readers furnish us with the name and address of the makers of the Daina dry battery?

THE first club run of the Scottish Automobile Club was fixed to take place on Thursday, the 19th inst., to Stirling, where permission had been obtained for the entrance of the cars to the Highland Society's showyard.

MESSRS. ERNEST HUTTON AND Co., electrical engineers, of Northallerton, have been appointed sole agents of the Sports Motor-Car Company for the North of England, which includes Yorkshire, Northumberland, Durham, Cumberland, Westmorland, and Lancashire.

A TRIAL run of the new Pennington motor war-chariot was made on Thursday last week in the vicinity of Hamilton, N.B., when a maximum speed of nearly 50 miles an hour is said to have been attained. The car carries two quick-firing guns, and provides accommodation for five persons.

THE McLachlan Electric and Gasoline Motor Company, of Toronto, Ontario, have lately introduced a new double-cylinder petrol motor of 5 h.p. The two cylinders are arranged opposite to one another, the two piston rods connecting up to a common crank shaft. The length of the engine is 2ft. 9½in., and the width 22in., the weight being about 300lb.

WHAT is described as being the first motor-cycle delivery service in the United States has just been started in Hartford, Conn., by the Columbia and Electric Vehicle Company. The carriers are petrol motor-tricycles. Their work is directed from a central office, where they are on call, together with passenger vehicles capable of carrying four people. The packages are brought from the stores to the central station, where they are sorted according to the districts in which they are to be delivered. The vehicles can attain a speed of about twelve miles an hour. By a system of collecting packages on a number of routes each day, the service is available to those who have a comparatively small number of deliveries to make.

THE CAPEL MOTOR-CAR.

THE accompanying illustration shows the motor-car designed and built by the late Mr. H. C. Capel, of Messrs. Capel and Co., 168, Dalston Lane, London, N.E. The vehicle is designed to carry two persons, but is provided with an auxiliary seat in front on which a third person may be accommodated. It is so arranged that any part of the mechanism can readily be exposed and examined. The seats are not fixed to the body of the vehicle, but are hinged forward of the foot-rest, so that they fold over and leave everything underneath exposed. They also have springs interposed between them and the body of the vehicle, so that they are completely isolated from all vibration.

The control of the vehicle is exceptionally easy. The three forward speeds and the reverse are all controlled by the movements of one handle placed at the right of the driver. Increase of speed is obtained by moving the handle laterally from right to left until it comes opposite a short quadrant, upon which it is then pressed forward, which has the effect of causing a chain to grip and give motion to the car. One of these quadrants is provided for each separate speed—three in number—and pulling the handle backwards from any one of the quadrants has the effect of throwing the car into the back gear, and thus applying a powerful brake. This is described as being an important point in the

design of the car, as, no matter at what speed one is travelling, the simple action of pulling back the handle will bring up the car.

The steering is also designed with a view to safety and ease of steering, the pivot of the steering lever lying just under the left elbow of the driver, and the handle reaching forward from there forms a convenient rest for the arm, and in steering the handle is moved to point in the direction the car is required to go. Another advantage is that if the car should strike any obstacle when running no strain whatever comes on to the steering handle. This feature is obtained by a special system of levers situated on the fore axle, which renders the steering both sensitive and easy. The starting handle is also very conveniently situated at the right hand of the driver, and can be operated from the seat; it sets the motor in motion by means of a disengaging rack and pinion, which engages with the crank shaft when the handle is pressed down.

The frame of the vehicle is of aluminium and forms the motor support as well as forming two tanks, one for petrol and one for water. The latter hold about five gallons each, the water being economised by being cooled in a Clarkson-Capel cooler, which is hung under the front of the car, where it has the full advantage of the air currents. The water is forced through this cooler by means of a small rotary pump which revolves at the same speed as the motor.

The engine is a two-cylinder one of four b.h.p., having cylinders 3 inches diameter and 5 inch stroke. When stopping, by means of auxiliary cams acting on the exhaust

valves the compression is released, which enables the motor to be turned easily by hand for starting again; then on starting after taking a few explosions it again puts on the compression. The ignition is timed in the same way; as the speed increases, the firing is made earlier and *vice versa*. The speed of the engine is also automatically governed. This last operation is, however, within certain limits, under the control of the driver, who by moving a button may increase or decrease the speed of the motor. All these operations are performed by means of a centrifugal governor placed on the half speed shaft which is under the motor and is operated by a worm wheel fixed between the cranks.

The variable speed gear is composed of two sets of leather-covered cone pulleys one above the other, on which run loosely leather-covered chains, one or other of which is put into action by being pressed tight on to its pulleys by means of a jockey pulley operated from the handle above described. The construction of the chain and pulleys gives, it is claimed, all the advantage of a belt drive with none of the disadvantages due to stretching, and also gives great compactness and little friction. From the lower set of pulleys motion is transmitted to the driving wheels by means of gear wheels which mesh with the differential gear fixed on the main axle. The gear wheels are enclosed in a dust-tight case.

CORRESPONDENCE.

DOES PETROL DETERIORATE?

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In answer to your correspondent W. W. Hardwicke, M.D., *re* "Deterioration of Petrol," published in your last issue, I have come to the conclusion (borne out by experiments made some months ago on the specific gravity of petrol and its constituents), that:—1. The mechanical results obtained from motors using petroleum spirit are entirely dependent upon the specific gravity of the spirit. 2. That petrol does deteriorate in explosive effect when exposed to the air, particularly when the volume exposed is not more than a gallon or so.

The experiments bearing on the queries put forward by Dr. Hardwicke are as follows (the French metric and thermometric system have been used):—One litre (1,000 cubic centimetres—ccs.) of Pratt's motor-car spirit was fractionally distilled, the fractions or portions of the spirit being collected and measured at different temperatures, and the specific gravity of each fraction determined. The results are appended:—

TABLE SHOWING INCREASE OF SPECIFIC GRAVITY OF THE DISTILLED FRACTIONS.

Fractional Distillates.	Temperature at which Distilled.	Volume of Distillates.	Specific Gravity of Distillates.
No. 1	Between 55°C. - 64°C.	360 ccs.	0.655
" 2	65° - 75°	315 "	0.675
" 3	75° - 90°	110 "	0.687
Residue in Distilling Flask.	—	Vol. 185 "	0.742

TABLE SHOWING DIFFERENCE OF SPECIFIC GRAVITIES.

Between.	Difference of Specific Gravities.
Nos. 1 and 2	= 0.02
" 2 " 3	= 0.012
" 1 " 3	= 0.032
" 3 " residue	= 0.055
" 2 " "	= 0.067
" 1 " "	= 0.087

From the tables it will be seen there is a considerable difference between the specific gravities of the first and second distillates and that of the residue from the distilling flask, namely, 0.087 and 0.067 respectively, and also between No. 3 and the residual

spirit, namely, 0.055. The other differences are less marked, but nevertheless appreciable. It is therefore an easy matter to see how, by continual evaporation of fresh petrol as in carburettors, a period will arrive at which the gravity of the spirit increases to such an extent that either efficient carburation will not take place, or, if it does, will not give rise to the explosive force which obtains when fresh petrol was being consumed in the motor.

This is owing to the fact that the higher hydrocarbons contained in petroleum spirit are more difficult to ignite, and when ignited do not have such a potential power of doing work as the more volatile portions that have been consumed; consequently the efficiency of the motor is lessened. The lower hydrocarbons of the methane series, such as normal pentane, boiling point 37 deg. C., hexane b.p. 69 deg. C., and heptane b.p. 98 deg. C., are as indicated—volatile liquids, and are the chief constituents of "common or garden petrol." When the greater portions of these are volatilised the petrol is said to be "stale" or "flat," and consequently unfit for use. The same remarks apply to petrol after it has been exposed for any notable time to the evaporative action of the atmosphere.

Yours truly,
W. G. BELL.

7, Loudoun Road, St. John's Wood, N.W.,
July 17th, 1900.

AN IMPROVED MOTOR-QUADRICYCLE.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In reference to above, I forward you particulars and illustration of a quadricycle fitted with a water-cooled Aster motor of 3 h.p. One frequently sees these machines about here, and an owner of one (uninterested in their manufacture) has given me a satisfactory account of his experiences with the machine in question. The front seat, by the way, is detachable, but the machine remains a quadricycle.

Yours truly,

Paris, July 19th, 1900.

J. HUMPHRYS.

[We hope to give an illustration of the vehicle in an early issue.—ED. M. C. J.]

THE 1,000 MILES TRIAL.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have been expecting every week to see some report as to the breakdowns, repairs, and incidents relating to the principal cars competing in above trial.

I am given to understand that the cars taking first and second prize in Class A had serious breakdowns, one failing to report itself on two sections of route, and the other repaired almost a new car.

These sort of tricks on the part of cars are just what the buying public watched the Trial for, but I for one have seen nothing to guide me as to which car was the most reliable for

Yours truly,

Reading, July 14th, 1900.

A PURCHASER.

P.S.—It would be valuable information to know the actual cost per mile run of the principal competing cars for fuel, repairs, oil, etc.

WE learn that Mr. C. Johnson, the secretary of the Automobile Club, has placed an order with the Sports Motor-Car Company for a Mayfair voiturette.

FROM various standpoints, sanitary, humanitarian, and otherwise, the substitution of motor power for the horse in connection with vehicular traffic is regarded by the *Sanitary Record* as "essentially preferable," while on economic grounds it may be found "equally desirable."

THE Automobile Club of Columbus has just been formed at Columbus, Ohio, U.S.A. At the first meeting the matter of a proposed speed limit ordinance came up for discussion, and it was suggested that the various members of the municipal council should be given a practical demonstration of the ease with which a motor-vehicle can be controlled. A resolution was also adopted providing that the speed limit of motor-vehicles should be twelve miles an hour instead of the slower speed proposed.

ELECTRIC IGNITER FOR STEAM VEHICLES.

WE herewith illustrate an electric device for igniting burners in the furnace of steam vehicles, which has lately been introduced by Messrs. A. L. Bogart and Co., of New York. Figs. 1 and 2 represent, respectively, the rear and side view of a "Locomobile" Company's car, with

FIG. 1 AND 2.

the igniting device attached in place; parts of the frame work in either case being shown broken away, so as to more clearly represent the position and relative size of the attachment. Fig. 3 is a diagrammatic view of the entire apparatus employed. In this latter view the spark-producing device is lettered "Igniter," which contains the electro-magnetic vibrator operating the sparking contacts at the upper end of the tube which surmounts it. The sparking tube passes through one of the air pipes in the furnace as indicated by the dotted lines. A B C represent the iron brace, which rigidly supports the igniter in place, and is secured to the under side of the body of the wagon by screws B C. Dotted lines show the electric wiring circuit connecting the igniter, push button, and battery, which latter is contained in a cylindrical case of neat design, as shown.

FIG. 3.

We are informed that no technical knowledge is required in the installation of the apparatus, so that any vehicle owner can attach it himself without sending to the manufacturers.

THE *Madras Times* states that Messrs. Massey and Co., the well-known engineers, of Madras, are building a motor-car, the design of which is their own, at their works.

SOME additional land has just been acquired at Unterturkheim, Wurtemberg, by the Daimler Motoren Gessellschaft, on which an extension to its already large works is to be built.

PROFESSOR V. L. EMERSON, of Ottawa, Ontario, is said to be at work on what he claims will be the fastest and most powerful automobile ever constructed. The vehicle will be operated by a hydrocarbon motor, which, it is expected, will develop between 30 h.p. and 40 h.p. The gearing will be designed for a speed of 30 miles an hour, but if necessary Mr. Emerson claims that he can run the machine fully 60 miles an hour.

MESSRS. GROUT BROS., of Orange, Mass., have introduced a new steam carriage. Its general design is on the lines made familiar by the "Locomobile." The front spring is a reversed elliptic, and the frame also shows minor modifications. The engine has a phosphor bronze frame and cylinders of grey iron, the other parts being drop forge steel. The boiler is of copper, with 300 tubes and 45 square feet of heating surface, and is hydraulically tested to 600lbs. The working pressure is 165lbs., controlled by an automatic regulator, and the safety valve is set at 225lbs. The water pump is worked by the engine, and can be regulated by the operator.

MOTOR-CARS ON THE CONTINENT.

(From our Own Correspondent.)

The Jenatzy Case.

LAST week, in these columns, I referred to the appeal of Monsieur Santié against the judgment of the Ninth Chamber of the Paris Courts, whereby M. Camille Jenatzy was acquitted of the charge of homicide by imprudence arising out of the accident by which Madame Santié lost her life on January 21st last. As I then stated, a week's adjournment was ordered, and on Wednesday, the 11th instant, the hearing was resumed. The judgment now given completely reverses that of the lower court, for it holds that M. Jenatzy should have sounded his horn, and that he was travelling at too great a rate of speed at the moment of the accident. The sentence passed condemns M. Jenatzy to three months' imprisonment with reprieve, £20 fine, £24 damages to Monsieur Santié, and £6 per year to each of the five children of the victim until they come of age. As some of these latter are but infants the sentence is particularly heavy; indeed, the entire judgment comes, after the ruling of the lower court, as a considerable surprise to the members of automobile circles. Had M. Jenatzy been compelled to undergo the period of imprisonment immediately, Paris-Toulouse would not see him as a competitor, but at the moment of writing I believe that he will figure among the starters, and he will assuredly have to be reckoned with in considering the probable winner.

Racing at Nantes.

MOTOR-CYCLE racing is for the time being an almost unknown quantity in France, and the few events that do take place are organised in the provinces. Nantes celebrated the 14th instant, the day of the Fête Nationale, by holding a big cycle meeting on the Longchamps track, and among the events decided was a fifty kilometre motor-cycle match between the three well-known Parisian *chauffeurs*—Fossier, Vasseur, and Demester. The struggle for the lead was hotly contested during the first ten laps by Fossier and Vasseur, but then Demester ran into first place, a position which he retained until the finish. The ten kilometres were covered by him in 10min. 4sec., the twenty in 20min. 10½sec., and the thirty in 30min. 50½sec., Fossier and Vasseur meanwhile struggling for second place, always about a lap behind the leader. Demester continued to travel without accident or incident, while his less fortunate competitors suffered alike from a variety of troubles, so much so indeed, that at the fortieth kilometre they were twenty laps behind the leader, whose time for the distance was 41min. 5½sec. At the finish Demester's time was ascertained to be 51min. 59½sec., Fossier being twenty-nine and Vasseur thirty-eight laps behind him. The last named was compelled to retire without completing the distance through lack of an inner tube, that on one of his wheels having punctured. It is possible that other matches between these three men will take place at an early date.

At Nice.

IF any proof were needed the recent chase and capture by the Mayor of Nice of a law-breaking motor cyclist should conclusively demonstrate to those reckless *chauffeurs* who delight to terrorise the public that Monsieur Sauvan is not a gentleman to be trifled with, and that the sooner they relinquish their foolhardy and selfish conduct the better it will be for them. The incident in question occurred about six o'clock on the evening of Tuesday, the 10th instant, a time of day when the far-famed Promenade des Anglais is crowded to excess. Tranquilly seated in his carriage Monsieur Sauvan was chatting with some friends when his attention was directed to a motor cyclist issuing from the public gardens at a tremendous rate of speed. Heedless of the cries of the passers-by, and the appeals of the police, regardless even of the mayor's orders to stop, the *chauffeur* raced by like a flash of lightning, leaving frightened people and terrorised horses in his train. But his just retribution was to come, for M. Sauvan promptly gave chase,

and followed him down a *cul-de-sac*, which he had entered blissfully unconscious of the nearness, or even of the existence, of the pursuit. Placing his carriage right across the road, the mayor effectively blocked the sole means of exit, and the culprit having been secured, a summons was promptly taken out against him, which will assuredly be followed by the severest sentence that M. Sauvan can pass upon him. It is truly disgraceful that any motor-men should so far forget the good feeling and benevolence hitherto displayed by the Nice authorities towards local automobilism as to commit such outrages, and it is indeed a pity that these *chauffeurs* cannot be singled out and severely punished without making the whole automobile community to suffer by the framing of more rigid regulations. I understand that M. Gondoin, the president of the "A. C. N.," has already notified the authorities of some of these motor-men who so abuse the police regulations, and the club can be depended upon to lend hearty co operation in putting a stop to this evil.

An Accident at Tours.

ON Friday last a most regrettable automobile accident occurred in the neighbourhood of Tours, whereby two of the four occupants of the car lost their lives, and a third sustained serious injuries. The mishap took place at an early hour in the morning on the Amboise road, which, at the scene of the accident, runs by the side of the river Loire. M. Vandeveldt, a Belgian engineer, accompanied by his wife and a fellow countryman, M. le Comte de Thuidzeyle, were travelling in the direction of Tours, when suddenly one of the front wheels of the car struck a large block of stone which had become detached from the parapet bordering the river, and lay in the roadway. The vehicle not being fitted with irreversible steering gear, swerved violently and struck the parapet with great force, against the massive stones of which the passengers were thrown. The passers-by at once ran to the unfortunate travellers' assistance, only to find that monsieur and madame had been killed instantaneously. M. de Thuidzeyle, although badly contused and also burnt by the petrol, which escaped from the broken reservoir and was fired by the burners, is not in any danger, and will doubtless have quite recovered in a few days. M. Vandeveldt's servant, who was also in the car, fortunately escaped with only a few bruises, as his fall was broken by the awning of the vehicle. The terrible accident once again emphasises the importance of fitting every vehicle with an irreversible steering gear, and constructors will do well to study this question with the greatest attention.

THE Automobile Club of America is now talking of a run from New York to Boston, to be held some time in October.

A BOX of matches igniting in the pocket of one of the employees of the local motor-car company at Swansea has caused a blaze at the company's establishment. Fortunately little harm was done.

THE Right Hon. the Earl of Clonmell is another young member of the nobility who has recently become fascinated with motor-caring. Besides having placed an order for a racing Panhard, the Motor-Car Company, Limited, of Shaftesbury Avenue, are supplying him with one of their Decauville cars. This little sociable, which is intended for use in the vicinity of Dublin, is provided with a 3½ h.p. air-cooled, two-cylindrical motor.

THE employees of the coach-making departments of the Motor Manufacturing Company, Limited, Coventry, held their second annual beanfeast on Saturday last, the 14th inst., to Stratford-on-Avon. The party journeyed by rail to Leamington, where lunch was partaken of, and afterwards proceeded by brakes to their destination through the historical and ancient town of Warwick, arriving at Stratford-on-Avon about 1 p.m. A capital dinner was provided at the Old Red Lion Hotel, and aquatic sports and other amusements were indulged in during the afternoon. The return journey was made via Charlecote to Leamington, where the party retired to the Fox and Vyvian Hotel for a smoking concert. Votes of thanks were accorded to the secretary, and also to Mr. Geo. Iden, the latter being, however, unavoidably absent.

THE BÉGOT AND CAIL PETROLEUM-SPIRIT MOTOR-VOITURETTE.

AMONG the many new types of motor-vehicles to be seen at the Paris Exhibition is that which has lately been constructed by Messrs. Bégot and Cail, engineers, Rheims, France, and of which illustrations are given herewith in Figs. 1, 2, and 3. As will be seen, while adapted for two persons, an additional folding seat is provided at the rear, so that the car, which weighs complete about 8 cwt., can, if necessary, carry four persons. The frame of the vehicle is of tubular construction. The motor is of 4 h.p.; it comprises two cylinders, set at such an angle that the piston rods connect up to the same crank shaft; the diameter of the cylinders is 80 mm., and the stroke 90 mm. The ignition is electrical, while, for cooling purposes, the cylinder walls are provided with radial ribs, and the explosion chambers with water-jackets. The ignition is so arranged that the crank shaft receives one impulse at each revolution—that is to say, the explosions take place alternately in the cylinders. The normal speed of the engine is 1,200 revolutions per minute, but this can be regulated as desired by means of the variable electric ignition, which is controlled by a small handle on the steering pillar. The speed of the engine can also be varied by means of a handle which regulates the amount of carburetted air allowed to pass to the explosion chambers. The carburettor employed is of the constant level type; it can be seen in Fig. 3 to the left of the engine. The charge is drawn in automatically by the suction stroke of the motor. The pipe conveying the petrol to the carburettor is of a large section and is closed by a needle valve which can be set to allow any desired quantity of spirit to pass. The necessary air to form the explosive mixture is drawn in through three openings—two below the needle valve and one in the carburetting chamber proper. Of the first two openings one conveys warm air to the petrol, and the other cold air; the third opening is provided with a regulating device by means of which the amount of air allowed to pass to the explosion

chambers can be controlled by means of a tap located near the driver. The water circulation is maintained by a small pump. The water tank, which is located at the rear of the frame, is of special construction, it being pierced by a number of tubes through which the air can freely pass, thus greatly increasing the cooling surface.

Coming now to the transmission mechanism, it will be seen from the illustrations that the motor is located under a bonnet in the fore part of the frame. Four speeds and reverse motion are provided. The fly-wheel of the engine forms one half of a friction clutch, the other portion of which is carried on the end of a shaft in line

with the motor shaft. This intermediary shaft carries within the gear box seen in the plan, view Fig. 2, two sets of double gear wheels, of different diameters. These double gear wheels are so mounted on the shaft that while they always rotate with it they can be displaced laterally along it by means of a flat sinusoidal cam which works the two forks connected—one to each of the double gear wheels. A hand lever fixed at the right of the driver actuates, by means of a toothed sector, a pinion keyed on the cam shaft. By this means any one of the four-gear wheels can be made to mesh with its corresponding pinion on the countershaft. From this shaft the power is transmitted through bevel gearing to a differential cross shaft, and from this to the rear road wheels by the usual sprocket wheels and chains. The reverse motion is controlled by means of a foot pedal. When the hand lever is placed in such a position in the sector that none of the variable speed pinions are in mesh, the depression of this pedal brings a small spur wheel into gear

with both the two pinions which normally give the slow speed. Ample brake power is provided, there being a pedal-operated band brake on the differential shaft and band brakes on drums attached to the hubs of each of the rear road wheels, controlled by a hand lever. On the application of either of the brakes the friction clutch is automatically thrown out. Steering is controlled by a bar, although a hand-wheel can be substituted if desired; the wheels are of the cycle type, shod with pneumatic tires. Provision is made for taking up any wear in the driving chains, while special attention has been devoted to the lubrication of the working parts. The

FIG. 1.—GENERAL VIEW OF THE BÉGOT-CAIL CAR.

FIG. 2.—PLAN OF BÉGOT-CAIL CAR.

car can, it is stated, attain a speed of 30 kilometres (19 miles) per hour. Messrs. Bégot and Cail are, we understand, anxious to arrange for the introduction of their car into this country.

WE learn that Mr. R. Reynold Jackson has severed his connection with the Yorkshire Motor-Car Manufacturing Company of Bradford.

THE John O'Groats road map is the latest in the series of contour maps published by Messrs. Gall and Inglis. The route taken is from Inverness by Wick, a road of varied interest, though with only a few outstanding features or places of interest.

IN describing the automobile races at Ranelagh the *Sportsman* made mention of Captain Langrishe's "Pengot," Mrs. Kennard's "De Dion virturette," and Mr. Phillip's "Beht Duc." An Irish scribe describing the motor-car run to Killaloe saw a De Deri, a Morse car, an Aerial quad and several Daimlers.

FIG. 3.—FRONT VIEW OF BÉGOT-CAIL CAR WITH BONNET REMOVED TO SHOW MOTOR (for description see previous page).

THE Altha Automobile and Power Company, of New York, has been incorporated in Delaware, with a capital of £100,000.

THE Eastern Yacht Club, whose clubhouse is at Marblehead Neck, Mass., has fitted up a shed for automobiles belonging to members. Facilities for charging accumulators are provided, and extensions will be added when necessary. At present about ten or twelve members own motor-carriages.

THE Motor Manufacturing Company, Limited, ask us to mention that the voiturette driven by Mr. A. Goodwin in the hill-climbing contest at Tilburstow Hill was fitted with one of their $4\frac{1}{2}$ h.p. water-cooled engines; a motor which they are now making as a standard pattern.

ARRANGEMENTS are said to be on foot for the establishment of an automobile factory in Ottawa, Ont. A number of gentlemen from Toronto, interested in the enterprise, have been in the Canadian capital looking over the ground. The establishment will be the Canadian branch of an American firm engaged in the manufacture of these vehicles.

THE Hon. F. Foley, of Barwell Court, Chessington, Surrey, has, we learn, just purchased a Roots and Venables heavy-oil car. Baron de Reuter, of telegraph fame, has also ordered a special car of elaborate construction of the same firm. The Roots and Venables car which competed in the 1,000-mile Trial has been purchased by Mr. H. C. E. Zacharias, who travelled as passenger for 320 miles.

THE PROGRESS OF THE AUTOMOBILE.

BY PROFESSOR R. H. THURSTON.

THE automobile should be a self-moving carriage which, to realise the ideals and needs of the automobilist, must be safe, reliable, comfortable, well adapted to the special purpose proposed in its use, handy, as speedy as may be found desirable, light in proportion to power, compact, simple, elegant, manageable, and inexpensive, both in first cost and in operation.

The problem of the designing engineer in this case is that of producing a design and plan which, when executed by the builder, shall fully meet the requirements of the proposing purchaser. He must ascertain what are the best materials for the several parts of the structure, must combine them in a carriage graceful, light, strong, and comfortable, in machinery of maximum power with minimum weight and volume, combine carriage, machinery, and running gear in such manner as to insure ample factors of safety in every part, while keeping down costs to those at which the market will take the automobile with a rapid and constant expansion of demand. The duty of the builder is to select the best material, standardise the dimensions and proportions of the several elements of the automobile, put together the carriage, the machinery and the running gear, and erect the whole construction in a permanent and durable form, and to make his manufacture so systematic and scientific that, making a standard automobile in sufficiently large lots, he can put it on the market at a reasonable price with a reasonable margin of profit to all interested—including the buyer.

The problem in design is much the same as that faced by the naval constructor and naval engineer when called upon to build an ironclad, or, perhaps, more accurately, a torpedo-boat, and that of the aeronaut, who, more than the engineer in any other branch of mechanical construction, is compelled to seek combined lightness and power as far as science and art combined can co-operate in solution of this most attractive and important of problems in engineering.

The carriage may be made of any form that may be found desirable and satisfying to the aesthetic instincts of the user. The removal of the animal from before it leaves the designer comparatively free to express his most artistic and most utilitarian ideas and to combine these often opposing demands in whatever manner his genius and inventive power may devise as the best combination or the best compromise possible. Great changes in form and decoration of the carriage will doubtless be found among the other modifications which will come of this entire freedom in design and construction of the carriage as a structure which can now be fitted to meet the requirements of the user as to comfort and elegance without being in any way hampered by compulsory adaptation to the peculiarities of the animal organisation and temperament.

The running gear must be light, strong, and capable of transmission of the impelling force; but otherwise of such design and proportions as shall best suit the user and subserve his primary purpose. The motor must be just as light as is possible within the limits of entire safety. As the motor is a part of the non-paying load, as viewed from the economist's standpoint, its weight, however small, is a tax upon the automobilist, and the space occupied, however small and out of the way, is a waste also, either as loss of availability for stowage purposes or as detracting from the elegance of the automobile.

The selection of the type of motor for the purpose held in view by the designer is his first task, and experience has already shown that at least three motors are more or less adaptable to this work—steam, already used for a hundred years more or less successfully, the internal-combustion or gas engine, also proposed for the purpose in the early part of the nineteenth century and lately employed quite extensively, and the electric current supplied by a "storage battery" or "accumulator" carried by the vehicle. The first is the oldest and best known, both as to its availability and its economies; the second has rivalled, and in some directions outfooted steam in these later years; the third is used very extensively and is the ideal motor in its operation, but far from

ideal in its endurance and its cost. Steam is troublesome and involves some risks, and is costly to maintain; the petrol engine and its relatives are subject to some objections in manipulation and in the character of the motor fluid; electricity brings with it what at present are insuperable objections for general work and especially for long route operation, in its weight, bulk, and great cost and limited quantity of energy storage.

"The Trend of Progress" at present with this new apparatus of transportation thus seems to be along a bifurcated, in fact a trifurcated, path. It is at the moment apparently true that no less than three distinct types of motor and as many types of automobile are finding use, and in considerable numbers, each in its own peculiar and specially suitable line of development: the steam-carriage, the electric vehicle, and the internal combustion engine with its appropriate running parts. Whether these several lines of progress shall hereafter fall into one can perhaps be better guessed after some of the facts of the case are developed before the reader; but just now one can only guess the future. There is no definite knowledge to be obtained permitting a positive

of a form of aeolipile involving Hero's principle, that of reaction, as utilised in the Greek rotary steam-engine.

Sir Isaac Newton was probably the first automobilist inventor, but, like many later inventors, unfortunately, he did not succeed with his scheme. The Cugnot carriage, of 1770, however, was a real and a working machine, and the antiquarian engineer or automobilist who chooses to study its construction at the Conservatoire des Arts et Métiers, in Paris, where it is still preserved in good order, will admit that, for its time, it was a remarkable bit of engineering.

One of the first inventors of the gas-engine, Brown, in 1827, proposed its use for steam-carriages, and the steam-carriage itself was the precursor of the railway. Watt's steam-engine of 1784, his superintendent and manager Murdoch's model locomotive and automobile, and the full-sized and really successful steam-automobile constructions of Trevithick, at the commencement of the nineteenth century, were steps toward the modern automobile of no small importance, and practicable automobiles thus antedated the railway.

assertion. The probabilities may, perhaps, however, be stated after making a review of the practice of the day in its essential elements as bearing upon this question.

In reviewing the history of the possibly available motors for the automobile, one is struck by the curious fact that the most recent and the very lightest of all the existing types of modern heat-motors, employing steam as the working fluid, the steam-turbine, was actually known by the old Greeks and was described by Hero, two thousand years ago or more, and was even, possibly, old when Archimedes was seeking a lever-fulcrum from which to move the world. After all these centuries, the steam-engine has indeed caused the world to move and has given it an impetus in the single century just closing greater than had been acquired in the intervening centuries since Archimedes and Hero and their fellows of the Alexandrian era. How unfortunate that the old philosopher and engineer could not have found his fulcrum then and started this movement two millenniums earlier! It was not until 1680 that Sir Isaac Newton, proposing the construction of an automobile to be moved by steam, suggested the utilisation

The history of the automobile has illustrated well the tendency of the uninformed and the prejudiced populace to obstruct every economic movement essential to the most direct and effective social progress and to their own most rapid advancement. It was no sooner made a success by the inventors, mechanics and engineers of the early half of the nineteenth century than direct physical opposition and the restraints of legislation, urged in the interests of rival and less satisfactory methods of locomotion, brought the movement to a full stop, precisely as the same spirit had, in earlier days, destroyed Papin's steamboat and the "newly-invented" looms and the spinning frames of ruder times. It is only now that we find the legal pronouncement, through a New York court, that the ancient and inefficient must yield to the modern and efficient methods and mechanisms. Says this modern Solomon, recognising the spirit of the age, "If one should find it desirable to go back to primitive methods and trek along a city street with a four-ox team and a wagon of the 'schooner' variety it would possibly cause some uneasiness among the horses unused to such sights. Yet it could not be actionable, in

my opinion, if a runaway should result, provided due care were shown not unnecessarily to interfere with the use of the highway. Horses may take fright at conveyances that have become obsolete as well as those which are novel; but this is one of the dangers incidental to the driving of horses, and the fact cannot be interposed as a barrier to retrogression or progression in the method of locomotion. Bicycles used to frighten horses, but no right of action accrued. . . . The temporary inconveniences and dangers incident to the introduction of these modern and practical modes of travel upon the highway must be subordinate to the larger and permanent benefits to the public resulting from the adoption of the improvements which science and inventive skill have perfected."—*The Automobile Magazine*.

THE BENZ SPIDER PHAETON.

MESSRS. HEWETSONS, Limited, of Dean Street, Soho, London, W., have sent us the following brief particulars of the Spider phaeton illustrated on the opposite page—the latest production of Messrs. Benz and Company, of Mannheim. The vehicle has seating accommodation for four persons; it is fitted with a horizontal engine of 9 h.p. The crank shaft works in an oil-containing case, while a central lubricator supplies the oil for the working parts. The ignition is electrical, and the cylinders are water-jacketed, the water tank being located in the fore part of the frame. Four speeds forward and reverse motion are provided, the car being, it is claimed, able to maintain an average speed of twenty-five miles per hour. Steering is controlled by a horizontal hand-wheel.

WE learn that Mr. Frank F. Wellington has sold one of his 7 h.p. Aster racing machines to the well-known cyclist, Mr. H. A. Phelps, of the Catford Club.

MESSRS. P. SOUVESTRE AND COMPANY, late of Liverpool, are now making their headquarters in Paris, and have appointed the London Autocar Company, Limited, of Gray's Inn Road, W.C., their sole agents in Great Britain.

A NEW voiturette has arrived at Messrs. W. Newton and Company's establishment in Westgate Road, Newcastle, from the Progress Motor Works, Coventry. It was driven from Coventry by easy stages, leaving there on Friday and reaching Newcastle on Saturday evening last.

WE regret to learn that Mr. C. C. Potier, Sutton, met with a serious accident on Monday evening. He was riding a motor-tricycle on Banstead Downs, near to Sutton, when he was thrown off. He was found in an unconscious state, and a doctor who was summoned discovered that he was suffering from concussion of the brain. On regaining consciousness Mr. Potier was removed home in a trap.

A HURRIED run through the Daimler Works, Coventry, was made last week by our Midland correspondent, who reports that this firm are working almost night and day in the execution of orders. We understand that the Motor Manufacturing Company, Limited, Coventry, are in a similar happy position.

MR. E. L. STRONG, president of the Cleveland Automobile Club, Mr. Walter Root, and Mr. C. S. Ingalls, also members of the club, with guests, have started on a Canadian tour in motor cars. Going by boat to Buffalo, they will thence cross to Canada, at Niagara, and will visit Hamilton, London, Sarnia, and Port Huron, returning to American soil at Detroit, whence they will return to Cleveland by steamer.

OUR Midland representative had a short run this week on a Coventry Motor Company's car, in company with the manager, Mr. W. A. Taylor. The speed of the vehicle is limited to fourteen miles per hour, and this speed can be maintained on all ordinary up-gradients. Down hill the motor can be disconnected and allow the car to run free, thus giving the engine every opportunity of cooling down. Fitted with pneumatic tires, and weighing 3½ cwt., the car runs as silently as a bicycle down hill. The price of this car is not more than £100, and, for a light two-seated vehicle, fitted with a 3 h.p. De Dion engine, is one of the cheapest cars on the market.

THE GEORGES RICHARD SPARKING PLUG.

AN improved sparking plug has lately been adopted by the Georges Richard Company, of Paris, whose cars are now being introduced into this country by the Automobile Manufacturing Company, Limited. The ordinary plug consists of a metal spindle passing down the centre of a porcelain tube, its end being near another rod which is connected to the main body of the motor. Between the points of these two rods the spark passes. The rod passing down the axis of the plug is fixed either by some kind of cement or by two nuts, which hold it at the ends only.

These two systems have their disadvantages. Under the influence of the high temperature cements deteriorate; while, on the other hand, if the rod is fixed by means of nuts, it often happens that, owing to the difference in the expansions of the rod and the porcelain, the joints are altered in such a way that a current of gas or air sufficient to extinguish the spark may be produced around the rod.

The illustrations below indicate the method by which the Georges Richard Company seek to avoid these causes of breakdown. *A* is the porcelain tube enclosing a metal rod, *B*, at the end of which is a head, *C*, separated from the end of the porcelain tube by a copper washer, *a*. Close to the head, *C*, is the rod, *b*, which is connected to the mass of the motor. At the other end of the tube is an asbestos washer, *c*, over which is a thin copper washer, *d*. A spring, *R*, presses against this washer. According to the usual practice the rod, *B*, has its end threaded to receive the nut, *D*, by means of which the rod, *B*, is firmly held in the porcelain tube; this nut, *D*, receives the electric conductor, *e*, the latter being held in position by the thumb-screw, *f*.

Owing to the spring, *R*, which is compressed by the screw, *D*, the head, *C*, is pressed firmly against the tube, *A*, and there is also a tight joint at the other end between *c*, *d*, and *A*. Thus a good joint is claimed to be formed, which does not allow the passage of gas or air when the parts expand, the difference in expansion being met by the action of the spring.

APPLICATION is about to be made to the Dominion Government for a charter incorporating the Canadian Motor-Vehicle and Battery Company, with a capital of £400,000. Hamilton, Ontario, is to be the headquarters of the company.

THE Allgemeine Radfahrer Union and the Alsace-Lorraine Automobile Club will, to-morrow, carry out an automobile race from Strasburg to Rheinau and back. The race is divided into four categories—(1) Racing cars; (2) Touring cars weighing more than 500 kilos.; (3) Touring cars weighing less than 500 kilos.; and (4) Motor-cycles.

THE Nottingham Autocar Company, Limited, has been registered with twenty members, each liable for £1, to manufacture and deal in motor-cars, vehicles, cycles, etc. The first directors are T. H. R. Bayley, P. Huskisson (managing director), and G. K. Hibbert. The registered office is at Starey's Horse Repository and Carriage Works, Upper Parliament Street, Nottingham.

PARIS EXHIBITION NOTES.

(From Our Own Correspondent.)

AS a very natural consequence of the position which the Mors firm holds in the racing world, their exhibit at Champ de Mars daily attracts a crowd of enthusiasts, who certainly find no lack of interest in the display. First of all, right in the centre of the stand there is to be seen a magnificent bronze, M. Antony's trophy, gained by him in last year's Paris-Saint Malo race, and this is backed by a series of excellent photographs representing an infinity of types of cars built by the Grenelle firm. Five of these designs are actually in evidence upon the stand, and they range in size from the dainty "Petit Duc" to the mighty 16 h.p. car. I suppose that there are but few automobilists in England who do not know the "Petit Duc," by sight, at any rate, and to those who have never ridden in it let me recommend them to take the earliest opportunity of doing so, for they will assuredly enjoy the drive. Another type shown is a 8 h.p. dogcart, with both seats, each carrying two persons, facing forwards. This vehicle is beautifully finished, the carriage work being by Rothschild, but the lines are stiff and far from graceful. The third car shown is a victoria on an ordinary—that is to say, not dropped—frame, and it appeals directly to that class of buyer who is on the look-out for a highly-finished town carriage. The motor attached is one of 6 h.p., and the carriage work is by Rothschild. Number four is a 16 h.p. vehicle, the body being of the *tonneau*, or *wagonette* type, painted a snowy white. It is a truly magnificent car, and as one faces it directly its rakish appearance gives the impression of great speed. No need to add that this impression is not an erroneous one, for all the world knows what the 16 h.p. Mors did in last year's races.

As probably but few English visitors will have an opportunity of seeing this season's speed cars, let them have a good look at this Mors vehicle and then picture to themselves that the new racing automobile is fitted with an engine developing nearly double the power of that used on this white monster. It will serve as a line, if not a very accurate one, at any rate. The carriage work is by Rothschild also, and with its snowy exterior and red upholstered interior, the car presents a very smart appearance. I have purposely reserved the tit-bit of the Mors exhibit until the last, but I can assure you that it is well worth waiting for. The new 10 h.p. car, as shown, is, to my mind, the most beautiful carriage in the whole exhibition. Built on similar lines to the 16 h.p., the new type presents the same racy aspect as does the larger vehicle, and Rothschilds have designed for it a remarkably pretty body. Four-seated, all facing forward, an ingenious contrivance is attached to one half of the rear seat which lifts upwards automatically upon the door at back being opened, so enabling ready access to the rear of the carriage. Attached to the pillar of the inclined wheel steering gear is an accelerator, and on the right of the driver a lever actuating the gear wheels. Three speeds and reverse are provided. The large round carburettor, as used on the new 16 h.p. cars, is employed. This carburettor is divided into four, by which

means each cylinder is assured of its proper proportion of the explosive mixture. The Mors firm have certainly made, with the production of this car, another step forward, and everything points to its becoming one of the most popular vehicles of the day.

Among the electric vehicles exhibited the three cars upon the stand of the Société Française pour l'Industrie et les Mines, of 45, Boulevard Haussmann, Paris, are particularly worthy of attention, for they are built upon the system of M. Krieger, one of the earliest pioneers of the electric car. The most striking of the three vehicles is the three-seated automobile, carrying its accumulators in front, and built upon the lines of M. Krieger's own well-known racer. It is of very handsome appearance, and for the man who is desirous of securing a large range of action it is the very class of car required, as by reason of its dimensions a great number of accumulators can be carried. The other vehicles shown are a coupé and a victoria for town work. All three cars carry their motors on the front axle, and are furnished with Fulmen accumulators.

Needless to say that some of the handsomest cars are to be found on the Peugeot stand, for the vehicles built at Audincourt are unquestionably among the most elegant of all the types upon the market. Indeed, there are many motor men who regard the Peugeot as the car, at any rate so far as appearance goes. Upon the stand under notice will be seen what is rather a departure for the Audincourt firm. This is a wagonette, or *tonneau*, furnished with wheel steering and the motor in front. The engine employed is the usual horizontal type, developing 8 h.p., although I understand that the firm are now building vertical motors. A couple of stylish cars for town work are a coupé and a cab victoria with lifting wooden apron. Both are fitted with 8 h.p. motors carried behind, and are built on dropped frames.

A dainty example of the 4 h.p. voiturette is also in evidence, the car in this case being four-seated and painted white. A fourth car carrying an 8 h.p. engine is a phaeton providing for four passengers all facing forward, and fitted with a small seat behind. The collection is completed by a magnificent 12 h.p. landau, a truly noble carriage. The front seat provides room for a couple of passengers, and then comes a spacious and luxuriously upholstered interior where four people will find more than sufficient space. A "spider" seat at the back carries a couple of passengers, and the car is quite one of the striking features of the whole show. The motor is hidden away under the front seat, a method frequently adopted in the case of these large family carriages, but open to criticism as to whether it is conducive to the best results. Speaking from practical experience I do not believe that an engine gets a fair chance when so stowed away and when running a little hot it frequently conveys a sensation of uncomfortable warmth to that portion of the driver's anatomy where the back loses its name. But this by the way, and as the Peugeot carriage is not intended for extended tours the opportunities afforded to the motor for over-heating are not numerous.

(To be continued.)

THE BENZ SPIDER PHAETON. (For description see opposite page.)

STEAM v. ANIMAL POWER FOR HEAVY TRACTION.*

THE Lancashire and Yorkshire Railway Company has had a steam-lorry made by the Thornycroft Steam Wagon Company working since 4th December, 1899. The lorry was used for town delivery from the company's Salford depôt, near Manchester, until 10th February, when it was transferred to the same class of work at Great Howard Street Station, Liverpool, where it is still working. The car has run satisfactorily, and has been found to be about equal to two one-horse lorries. As, however, it has been used on all classes of traffic to ascertain its suitability, the results obtained vary somewhat. It has been found particularly useful in taking loads of about 3 tons on journeys where, owing to stiff gradients over a portion of the road, two horses would have ordinarily had to be sent, whilst in Liverpool it facilitates delivery in allowing of a direct route being taken over gradients which a horse-drawn lorry could only surmount by taking a circuitous route.

Up to and including 31st March the car had run on ninety-four days, covering a total distance of 1,033 miles, or 10·99 miles per day, not including the distance travelled in collecting loads in the goods yards. In these calculations Saturday has been counted as a full day, although the car has not usually on that day worked after 2.0 p.m. The total load carried has been 670·14 tons in 289 loads, giving 3·07 journeys, with an average load of 2·318 tons per day. During the ninety-four days the car has been in steam 1,021·5 hours, or 10·86 hours per day. Careful records have been taken of the coke and water used, and it has been found that 259·7 lbs. of the former and 191·7 gallons of the latter are the average daily consumption, giving an evaporation of 7·38 lbs. of water per lb. of coke. This latter is obtained from the company's gasworks at Horwich, being made from Wigan coal.

* Statement by Mr. H. A. Hoy, the Chief Mechanical Engineer of the Lancashire and Yorkshire Railway, on the working of a Thornycroft motor-wagon, forming an appendix to the paper read by Professor Hele-Shaw before the Institution of Mechanical Engineers.

It is found necessary to clinker the fire after about seven hours' running, the operation taking about five minutes. The coke consumed has been 234 lbs. per hour, or 22·05 lbs. per mile, whilst the water evaporated has been 17·14 gallons per hour, or 16·15 gallons per mile. The figures have been calculated from the days on which records were taken of both the water and fuel consumption.

The results day by day of a week's run in Liverpool are given in the above table; these will be noticed to be slightly higher than the average given. This is due to the fact that on the first few days, both at Manchester and Liverpool, the results were not good, owing to the drivers not being accustomed to the yards and the methods of working.

THE AUGÉ PETROLEUM-SPIRIT MOTOR-CAR.

HEREWITH we are enabled to illustrate the new two or three-seated petroleum-spirit motor-car lately introduced by Messrs. Daniel Augé and Co., of 92, Rue des Arts, Levallois-Perret (Seine), France. Fig. 1 gives a general view of

FIG. 1.—GENERAL VIEW OF AUGÉ CAR.

the car complete, while Fig. 2 shows the frame with body removed. The vehicle is propelled by means of a horizontal two-cylinder engine (Fig. 4), located in the fore part of the frame. There are several special features about the motor which are worthy of mention. It comprises two cylinders side by side, the pistons of which are coupled together by a double connecting rod with a single cross-head on the crank pin of the driving shaft. The motor is of the four-cycle type, and is arranged in such a way that one explosion takes place at each revolution of the crank shaft, that is to say, on the

outward movement of the pistons one cylinder is aspirating while the other is giving an impulse, while similarly on the return stroke of the pistons, one is compressing while the other is exhausting. A feature of the motor is that all the valves are so arranged as to form a detachable box, attached to the rear end of the cylinders. This box comprises a number of cocks arranged to be operated both by hand and automatically, and permitting a regulation both qualitative and quantitative of the explosive mixture. The distribution box comprises two explosion chambers communicating respectively with the interior of two cylinders, and an exhaust chamber capable of communicating with these two explosion chambers by the intermediary of two valves. To each of these explosion chambers is connected respectively a receiving chamber for the explosive mixture, capable of communicating with each of the explosion chambers by valves. Into the receiving chamber opens a cylindrical conduit on which are mounted special regulating cocks. The proportion of carburetted air and of atmospheric air admitted to the receiving chamber is controlled by means of one cock, while a second cock controls the volume of explosive mixture allowed to pass into the receiving chamber. This cock is composed of a hollow cylinder provided with two openings, and is capable of receiving two movements:—(1) A movement of

rotation on itself, controlled by a knob or hand-wheel which is provided with two pins traversing the bottom of the cylinder, this movement controlling the length of the orifice for the passage of the gases. (2) A movement of translation controlled by the governor which acts on the rod fixed to the bottom of the cock, by means of which the width of the orifice for the passage of the the gases can be varied. In this way the volume of the explosive mixture introduced may be regulated, either by hand or automatically by the governor. The speed can thus be varied by qualitative or by quantitative regulation. As soon as the

FIG. 2.—VIEW OF FRAME OF AUGÉ CAR.

speed of the engine increases, the governor acts on the spindle, allowing a smaller quantity of explosive mixture to pass.

The speed governor is mounted on the fly wheel. The feeding of the engine is effected according to its own requirements; an explosive mixture always of an equal composition enters the explosion chambers but in larger or smaller quantity; from this results, it is claimed, a variable compression, so that the force of the engine may be thus regulated between sufficiently wide limits by augmenting or diminishing at will the impulsive force of the explosive mixture, contrary to the ordinary method of regulation in which the speed is varied by suppressing the explosions. The exhaust valves are controlled by a series of levers and rocking arm, actuated by an eccentric mounted on a short intermediary shaft, and driven by means of gear wheels off the motor shaft at half the speed of the latter. A general view of the constant level carburettor is given in Fig. 5. It is described as being capable of micrometrical adjustment, permitting the spirit admission opening to be regulated to the 100th part of a milli-

FIG. 3.—PLAN OF AUGÉ CAR.

metre. The motor, which is capable of developing 5 h.p., runs at a normal speed of 600 revolutions per minute. By means of the regulating cocks and the electric ignition, Messrs. Augé claim to be able to vary the speed while running from between 300 to 1,200 revolutions per minute. The motor is, of course, water-jacketed, a radiating coil, in connection with the water-circulation, being located in the front of the car.

Coming now to the transmission mechanism, two speeds

forward and reverse motion are provided. As has already been mentioned, the motor is located in the fore part of the frame (see Fig. 3). On one end of the motor shaft is a pulley connected by a belt to a fast and loose pulley on a counter shaft about the centre

FIG. 4.—VIEW OF AUGÉ MOTOR.

of the frame. This shaft carries a series of pinions, working in an oil-containing case, and meshing with corresponding pinions on the differential shaft, on the two ends of which are sprockets conveying the power by chains to the rear road wheels. Steering is controlled by an inclined hand-wheel; the frame, which is of channel steel, is spring suspended on artillery wood wheels shod with pneumatic or solid rubber tires as desired. There are three brakes, one operated by a pedal and acting on the differential, and two controlled by a hand lever acting on drums connected with the sprocket wheels on the rear axle. The motor and

FIG. 5.—VIEW OF AUGÉ CARBURETTOR.

transmission gear all being mounted on a standard frame, Messrs. Augé are laying themselves out to supply these to carriage builders and others who may fit thereto any type of carriage body they desire.

THE Reuter Automobile Company has been formed at Dover, Del., to manufacture automobiles, etc. The capital is £100,000.

THE postal authorities at Buffalo, N.Y., are about to make some experiments with a petrol mail wagon. The car is to be built by the Conrad Motor Vehicle Company of Black Rock, and will carry from four to six bags.

AN association embracing all the operators of public automobiles in Chicago has been formed under the name of the Automobile Operators' Mutual Benefit and Protective Association. The object of the association is: To aid one another in time of need; to provide a club room and possibly later a club house where all operators when off duty may assemble and discuss the events and happenings of the day or night, and where the single men, especially, may have the comforts and privileges of a home and spend their time, which would be spent to less advantage elsewhere; to promote good fellowship among all concerned, and, in fact, to be of benefit and assistance to one another in every possible way.

THE LOUTZKY MOTOR-TRICYCLE.

FIG. 1 of the accompanying illustrations shows the motor-tricycle which has lately been put on the market by the Gesellschaft für Automobil-Wagenbau (system Loutzky), of 49, Französischestrasse, Berlin, W. It is fitted with a single-cylinder air-cooled motor, of which two sectional views are given

FIG. 1—THE LOUTZKY MOTOR-TRICYCLE.

in Figs. 2 and 3. The engine, which is capable of developing 2 h.p., is provided with electrical ignition; it is located inside the rear frame between the bottom bracket and the rear axle, and is entirely enclosed by the perforated metal case seen in Fig. 1. It is geared to the rear axle in the usual way. A feature of the machine is that all the control levers, i.e. compression, sparking, carburation, etc., are mounted on the handle-bar and not on the top bar of the frame as usual. The petrol tank has a capacity of

FIGS. 2 AND 3.—SECTIONAL ELEVATIONS OF LOUTZKY MOTOR.

four litres. In addition to the usual front wheel tire brake, band brakes on drums on the rear axle are provided. On the level, the machine can, it is claimed, attain a speed of forty kilometres per hour; when intended for use with a trailer it can be fitted with a two-cylinder motor giving 3½-h.p.

MOTOR-CYCLE RACING AT MANCHESTER.

SUCCESSFUL as have been the Manchester Wheelers' race meets in the past, none has equalled that which was held on the Fallowfield track on Saturday last, when a couple of motor-cycle events were included in the programme. The club was as usual favoured with fine weather, though threatening clouds hung over the ground before the racing commenced. The clouds notwithstanding, about 12,000 spectators gathered round the track. The motor-tricycle races were an interesting novelty, though more excitement would have been aroused had not Mr. C. Jarrott been allowed to win both the mile and the ten miles so easily. Jarrott's driving was much admired. He showed superior skill in "taking the corners." Unfortunately he afterwards suffered from his riding. His left leg was weak before starting, and his efforts to "take the corners" skilfully have caused him to strain the sinews of his foot. In the ten-mile race Mr. C. Machin, the holder of the hour record, was put out of it owing to a punctured tire, Jarrott winning by 2½ laps from Lee, W. Dunn, of Birmingham, being third. The neck and neck racing of the latter couple in the earlier part of the race provoked the enthusiasm of the spectators. The following were the results:—Mile Motor Tricycle Scratch Race: C. Jarrott, London, first; C. Machin, London, second; V. Lee, London, third; W. Dunn, Birmingham, 0. Won by five lengths. Time, 1min. 42 4-5sec. Ten Miles Motor Tricycle Scratch Race: C. Jarrott, first; V. Lee, second; W. Dunn, third; C. Machin, retired. Won easily. Time, 16min. 32 1-5sec.

FURIOUS DRIVING CASES.

AT THE Edinburgh Police-court last week Frank Harwood, a motor-car driver, in the employment of the Edinburgh Autocar Company, was convicted of driving a motor-car in a reckless and careless manner in Corstorphine Road, on Saturday, June 23rd last, in consequence of which the car collided with a cyclist named Williamson, throwing him off and smashing the bicycle. Accused was coming in the opposite direction, and drove round a vehicle and into Williamson, who was riding slowly and on his proper side. The bicycle was considerably damaged. A fine of £2, with the option of fifteen days, was inflicted.

At the North Holderness Petty Sessions, at Leven, last week, Mr. John W. Tanfield, of Beverley, cycle and motor-car agent, was summoned for having furiously driven a motor-car on the road at Seaton, to the danger of the public on the 6th July. The complainant said that he was riding a valuable horse when he saw the defendant approaching him in a motor-car at the rate of 20 miles an hour. He put up his hand for him to stop, but the defendant refused to do so, and he had to get off his horse. The animal took fright, and began to plunge and rear, ultimately laming itself and him. The defendant, who pleaded that he could not go faster than 6 miles an hour, was fined 20s. and 23s. costs.

Before the Guildford County Bench, last week, Mr. John Dennis, of Guildford, was summoned for furious driving at Woking, on July 1st. P.C. Shortridge stated that at 12.50 p.m. on Sunday, July 1st, he was at Mayford Hill, and saw a motor-car coming down the hill at a furious rate, followed by a motor-tricycle. He shouted for them to stop. When the defendant dashed past him on the first car, Sir John Baker's carriage was being driven up the hill, and his shout warned the driver, who pulled the horse right into the side, and so prevented a collision. The first car was going fully twenty-five miles an hour. He did not know who was in the first car at the time, but had since made inquiries, and would swear it was the defendant. Richard Mitchell, coachman in the employ of Sir John Baker, said that the car appeared to him to be going more than fifteen miles an hour, but he hardly had time to see it. He could not say who was driving it. For the defence, Mr. Joseph Millis, manager to Messrs. Pickford, Onslow Street, stated that he saw the defendant start on Sunday morning on a motor-tricycle, and he returned at one. Mr. Raymond Dennis corroborated this; and defendant then gave evidence. He denied emphatically that he was on the motor-car in question the whole of the day. Throughout he rode a motor-tricycle, which had no car attached, nor could any car be attached to it. The case was dismissed.

OTHEN v. THE ELECTRICAL UNDERTAKINGS, LIMITED.

In the Chancery Division of the High Court of Justice, on Saturday, Mr. Justice Cozens-Hardy had before him a debenture stock holder's action against the company and the trustees of the deed. All parties consented to take the judgment in the settled form with the appointment of a receiver and manager. Mr. Justice Cozens-Hardy appointed Mr. C. E. Hare receiver and manager to act as manager for four months, but would not give liberty to the receiver to borrow £500 to carry on the business, stating that the parties would have to take out a summons in Chambers for that purpose.

THE automobile recently imported into America by Mr. W. K. Vanderbilt, jun., which has occasioned so much excitement by its high speed, is said to be a 30 h.p. Daimler. A French mechanic is in charge of it, Mr. Vanderbilt himself not attempting to run it.

THE Motor-Car Journal.

Vol. II.]

LONDON, SATURDAY, JULY 28, 1900.

[No. 73.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

IN our last issue we mentioned that a motor-car was touring in the West of England. We have had the pleasure of making its acquaintance at Newquay, Cornwall, whither the hot weather had driven us from London. The car was of Daimler type, with wheel steering and a wagonette body, constructed to carry nine passengers—six behind, two passengers and driver in front. The “turn out” was altogether very smart; but whether it was a service vehicle or of private ownership we did not ascertain. It had been driven from Bristol, and made several days’ stay at Newquay, taking long motor trips daily, round the neighbourhood. The hills are what our friend Dominic Sampson would call “prodigious,” and the surface is none of the best. That a 6 h.p. car with nine passengers should be able to tour comfortably in such a neighbourhood shows that the ordinary type of motor-car is possible of doing all that any owner should reasonably desire. The touring party left Newquay on Saturday, intending to return to Bristol over the moors.

Newquay.

THE present is our first visit to Newquay, and we must confess our astonishment that there should be such magnificent hotels, considering the size of the place. That at which we are staying—the “Headland”—has only just been opened, and, as a matter of fact, our party was the first to “register” in the hotel book. The hotel is quite finished inside, and is resplendent in English oak and Devonshire marble, while the arrangements for the comfort of the guests will commend themselves to all. Practically the whole of the ground floor is a “lounge,” where afternoon teas, coffee after dinner, and smoking all day long may be indulged in.

The Lounge.

THOSE who have been on the many successful tours of the Automobile Club know how dissatisfied the ladies have been when after dinner they have been relegated to the drawing-room, while the mere male man has been content to finish his smoke in either the billiard or smoke room, leaving the ladies to their own devices. In all modern hotels the lounge is the most popular place, where either ladies or gentlemen have equal rights and meet on common ground.

Hotels.

WHEN we find a good hotel we are prepared always to call attention to it. The 1,000-miles Trial taught us that what were called hotels were—well, to say the least, unworthy of the name. We met all sorts. The inns were always comfortable and homely, and had no pretence to grandeur, while some of the anomalies called hotels in even leading towns

were beneath contempt. In Sheffield especially was this the case. We should not imagine, from opinions expressed, that there is a first-class hotel in the place. At the hotel where we stayed the milk was sent up to the breakfast-table in cream jugs not holding a tablespoonful. We measured, and therefore know. The butter was sent up in single small “pats,” and when either butter or milk was wanted the waiter had to go downstairs and fetch more. Those who were with us, and there were several, will well remember this. Our sympathy for good hotels and their need for sympathetic reference we are sure will be appreciated by our readers.

The Menu.

MR. TREVAIL, of Truro, is responsible for the growth of hotels round the Cornish coast, and his idea is that all the local produce should be used locally, and not sent away. This is all very well, and the notion is a good one; but the food, when one comes to the seaside and looks mostly for, is fish—fresh from the sea, where nature’s most bountiful harvest should be; but, *mirabile dictu*, the best of French chefs are not able to satisfy the customers in this direction in the Cornish hotels. Apparently, the Cornish men are content for their wives to take in lodgers, and they themselves are too idle to do aught but laze about; therefore the fish has to come from afar—say, Plymouth—and then has to travel in the broiling sun by rail and other means. Therefore the fish portion of the menu is always indifferent. Other *plats* in the hotels are as a rule excellent.

The Roads.

THIS Mr. Trevail is a very important public man in Cornwall, and we would urge upon him, now that he has erected such beautiful hotels, to attend to the roads of the county and make it possible for those who are likely to be his best customers to come and use his hotels. The roads we should not like to say are the worst in the kingdom, but we do not know what roads to compare them to. A General Wade is wanted to do for Cornwall what was done for the Highlands, and the result would be such an opening up of the Duchy as would bring prosperity to the county and pleasure to the tourist. The roads and lanes are so narrow that we have found ourselves wondering what would happen if a motor-car came across one of the Newquay coaches—many of them have five horses, two pairs and a leader. The only escape for the horses, if they desired to turn round suddenly, would be to jump the hedges.

The Latest.

THE scene was a country lane, and an old lady was in a wagonette, the coachman driving. “Oh!” said the old lady, excitedly, “there is one of those dreadful motors, Joseph. I know the horse will take fright. Hadn’t you better turn him round?” Coachman (who will have his own way): “Oh, let ’im alone, ’m; he’ll turn ’isself round, and pretty quick too, if he’s frightened.”

Dirt and Vibration.

At several garden parties recently held motor-vehicles have been well in evidence, and while nearly all observers are sympathetic in their opinion that "motors will be the vehicle of the future"—yet a qualification is generally made that they are "so dirty and they vibrate so." This remark, too, has been addressed to motorists—gentlemen wearing light gloves, frock coats, and silk hats, and to ladies in the most delicate of muslins. That it is also possible to get dirty in a railway carriage has been brought forcibly home to us in a 7½ hours' journey to the west. There was no water in the carriage, the heat was stifling, we had the windows open all the way, and the result was when we arrived at our destination we looked as if we had come up from a coal mine. We certainly have never got in such a state from motor riding. The vibration also was extreme, and it was impossible to sit still without wobbling, which we certainly do not find necessary when motoring; all of which goes to prove that people must say something and that something need not necessarily amount to sense.

Motor Dust-Carts.

SEEING that the Public Health Committee of the City of London Corporation could not get a dust cart propelled by electricity, the Streets Committee of that authority is seeking a motor dust cart propelled by steam. This should lead to some advance being made throughout the country in the same direction, for the presence of a motor dust cart in the City of London would unquestionably be a boon and demonstrate most thoroughly the advantages it possesses over horse-drawn carts for street refuse work.

Accidents in France.

THE *Vélo's* monthly record of accidents for May last has just appeared, and shows no less than 661 mishaps arising from horsey eccentricities. As a result of these accidents fifty-nine deaths occurred, and 602 persons were more or less seriously injured. Compared with these figures the automobile's record of thirty-nine accidents sinks into absolute insignificance. The latter moreover gave rise to but a couple of fatalities, the one occurring at Neuilly and the other at Sommières. In the former case a lady was knocked down and killed by an automobile in the Boulevard Maillot, while the mishap at Sommières was brought about by a horse taking fright at an approaching motor-vehicle and crushing the carter who endeavoured to pacify it. The bicycle accidents total up to eighty-three, and in three instances the results proved fatal to the victims. On the railway a like number of mishaps occurred, claiming sixteen deaths and sixty-seven wounded. The noble steed still maintains his advance over all other means of locomotion in the matter of accidents in spite of the marvellous number of automobile mishaps recorded daily by a certain section of the press.

Motor-Cars and Breweries.

BREWERS are watching automobile developments with considerable interest, for not only does motor traffic open up the prospect of economy, but it will do away with stables and hay stores about breweries. Cleanliness is absolutely necessary in connection with brewing, and as stable litter swarms with germs anything tending to do away with that is to be welcomed by the trade. In fact, where there are horses and stables there cannot be perfect cleanliness from the chemist's standpoint. And as motor wagons and cars give rise to nothing of a deleterious character their adoption would prove a boon to the brewing industry.

Irritating Courtesy.

PEOPLE who don't like motor-cars should not lose their tempers. The Hon. Lancelot Lowther was in a cab in Grosvenor Place when a motor-car passed. According to his own evidence the car went by like a flash of lightning, and the cabman pulled up his horse. Then, instead of stopping his motor-

car, the driver, a Frenchman, turned and kissed his hand to the occupant of the cab. This irritated the latter, who followed the car that had passed like "a flash of lightning" till he came across it in a mews. The sequel has been told in the Westminster Police Court.

A Trade Practice.

THE Motor Trades Association is seeking to influence manufacturers of motor-cars in this country to adopt the practice that has held good for many years in the engineering trade, viz., of declining to engage a factory hand until they have received a reference from the last employer of the applicant. A letter is now being sent, urging this advice, to all actual makers in Great Britain, and giving them a draft of a suitable form to be employed in this connection.

A Lincoln Appointment.

WE congratulate Mr. A. W. Goodall on his appointment to the management of the Lincoln Motor Bus and Parcel Delivery Company. It is a position he will be able to fill with credit, and the development of the new method of locomotion in the cathedral city is likely to be substantial under his guidance. We understand the company is running a regular public service, and doubtless its extension into the surrounding villages and hamlets will open up a good source of revenue.

Presence of Mind.

IN selecting drivers for automobiles something more should be looked for than the ability to drive and the knowledge requisite to understand the ways of a motor. Good general health is an essential factor in the driver's equipment. This is emphasised by an incident which recently occurred. The driver of a vehicle had a fit and lost control of the vehicle. The passenger, sitting by his side, promptly recognised the position, and sitting upon the driver's knees managed to steer the vehicle to the side of the road and then apply the brake. Fortunately a policeman was in sight, and the affair ended without mishap. But what would have happened had the passenger lost his presence of mind in such circumstances?

Glasgow's Motor Dust-Cart.

At the last meeting of the Glasgow Corporation the Mo-Car Syndicate Company report that, in view of the delay which has occurred in obtaining cells for the electric motor dust-cart on order, they are prepared to deliver a motor dust-cart to be driven by oil at a cost of £410 to £440, the cost of oil being about 2d. per mile. The Cleansing Committee have refused this alternative offer, being still hopeful of obtaining a dust-cart with an electric motor.

Another Gymkhana.

AN automobile gymkhana, similar to that recently arranged at Ranelagh, will be held at the Sheen House Club to-day (Saturday). No second prize will be given unless there are five entries. There will be six events, including a bending race, starting from "cold," motor-tricycle coat and waistcoat race, etc. Horses belonging to members of the Sheen House Club will be trained in the presence of automobiles from 11.30 a.m. to 2 p.m.

Canadian Postal Enterprise.

By the introduction of automobiles into the Toronto postal service and putting another clerk on the train which arrives in Toronto from Montreal at 6.50 a.m., the Montreal mail is now included in the first delivery throughout Toronto. The clerk leaves the city in the evening to meet the west-bound train, and by the time the train arrives the mail is all sorted to the central and various branch post offices. Auto-

mobiles, waiting at the station, hurry the bags to their destination in time for the first delivery by the postmen. By this means about three hours are saved in the delivery of Montreal letters in Toronto. The initial trip was made by Mr. J. E. McLeod, superintendent of the city post office. The automobiles have been furnished by the National Cycle and Automobile Company. The same system has been adopted for Montreal.

A Tribute to the Motor-Car.

At the last meeting of the Chippenham Rural District Council the surveyor gave a capital instance of the utility of motor-vehicles. He had heard that a gentleman went from Chippenham to Hereford, dined there, and returned to Chippenham the same day. It has often been urged that the motor-car is well calculated to promote friendship and sociability, and in country districts such examples as the one quoted at Chippenham might be multiplied.

A Note from the States.

SYRACUSE is an American town of about 130,000 inhabitants that has hitherto been chiefly associated with the bicycle trade. Now it is developing in connection with the automobile industry. At the present time, we learn from a correspondent in America, there are three or four factories at work turning out motors, and several vehicles of local production are running about the streets. The Locomobile Company has an agency there, and are doing very good business. Last month, in connection with the Syracuse Automobile Club, which has only just started, a run was arranged, to which Mr. C. G. Wridgway and Mr. W. Letts, late of the British Motor Coupé Company, were invited. The programme consisted of a parade around the town of about twenty-three motors, and a run out to Maple Bay, which is noted for its frog-leg suppers. The party arrived there late in the afternoon, sat down to an excellent meal, and journeyed back in the cool of the evening in a sort of go-as-you-like style. The English visitors spent a very pleasant time, and thought of the happy runs they had taken part in in the old country, and the fine times they had had on the Brighton road, coming to the conclusion that the roads in America are certainly very bad. Out into the country the roads consist simply of rut tracks. Some places have four or five inches of sand, so that a motor-car has to be well built to stand the wear and tear of such roads as these. The only motors seen in the States are the electric carriages and the little steam cars. Our correspondent's opinion of the latter is that they are built too light; but he admits that they go splendidly, and the manufacturers cannot keep pace with the demand, so well has the general public taken to this style of car. As soon, however, as a small petrol carriage to carry two people is put upon the market, he thinks there will be a great rush for them. The Mobile Company, of Tarrytown, of which Mr. John Brisbane Walker is the president, started selling the little steam cars at 650 dols.; so great has been the demand that a fortnight ago the price was put up to 780 dols., and even then the demand could not be met. They are turning out fifteen a day.

America to the Front.

"A SHORT time ago, when I was in Toronto," continues our correspondent, "I saw a new steam motor-car that was being manufactured there, something on the same lines as the Stanley, only that the engine was cased right in and was entirely dust-proof, and all the working parts were running in oil. It certainly seemed to me a very good idea. Of course, in the business on this side as well as at home, there are a lot of clever people who imagine that they are going to do something very wonderful, that no one else has ever done. One man told me quite confidentially that gears and belts for transmission were entirely wrong; that he was simply going to use compressed air as a means of transmission, and he would be able to have any speed he wanted. I can see more plainly every day that the American people are realising that to build a suc-

cessful motor they must work something on the same lines that we have been working on in England, France, and Germany for the last few years. In another eighteen months' time America will be very well up to the front in the manufacture of automobiles and accessories."

Motor-Car Hash.

SCARCELY a weekly paper catering for the wealthy classes has not its column devoted to automobilism. These contributions vary in many particulars, and few are really satisfactory, those in the *Field* being the most accurate and reliable, as it is about the only one that treats the subject in a serious and practical form. The *Traveller*, the latest addition to the ranks of the sixpenny weeklies, has a column of motor-car notes of a very general and discursive character. If our contemporaries think to interest their readers they will have to give really less ancient and more practical information than is at present the case.

MR. F. H. BUTLER AND HIS 6 H.P. PANHARD—MISS BUTLER AT THE HELM.

A Ferrying Difficulty.

A CURIOUS question has arisen in the fashionable American town of Newport. It appears that the ferry company, whose boats afford the only means for vehicles to reach Narragansett Pier, has refused to carry vehicles propelled by gasoline, and Newport automobilists are warm over the decision. Some strong protests were made, but the company appealed to the supervising inspector-general, who decided that Section 4,472 of the Revised Statutes absolutely prohibits the ferriage of naphtha or petrol on either freight or passenger steamships. Of course the statute was framed before automobiles were thought of as popular means of transport, and in view of the rapid extension of their use the situation created by the statute, if it should be generally applied, would be clearly impossible. Automobiles, whether petrol or other, must be ferried; and to empty the petrol tank on one shore and purchase a fresh supply on the other would be both impracticable and ridiculous. The danger involved in the fluid's retention, in the carefully guarded tanks provided for it, and with the motor quiescent, is insignificant. It is hardly too much to say that the ferry-boat is exposed to more risk in the act of crossing from other boats, stress of weather, and its own boilers than it would be from half a dozen petrol carriages. A measure framed in the interest of public safety, to prevent the carrying of petrol in bulk or in loose cans, should not be used contrary to public utility.

PARIS EXHIBITION NOTES.

(From Our Own Correspondent.)

A DISTINCT novelty is the motor-bicycle with speed-change gear exhibited by MM. Chapelle and Chevallier, an illustration of which is given herewith. Personally, I am by no means an advocate of the motor-bicycle, but, as they go, I find M. Chapelle's machine to be a capital one of its kind, if only by the fact that the motor is placed at the lowest point of the frame. Whether a speed-change gear is actually required upon an automobile of so light a description is a matter of opinion, but for those who consider it to be an unnecessary encumbrance MM. Chapelle and Chevallier build another type of motor-cycle without it. In both cases the motor carried is of $1\frac{1}{2}$ h.p. The two-speed machine is provided

costs £42, while the price of the other is £35. MM. Chapelle and Chevallier also sell their one and a-half horse-power motor alone, the price of which is £19.

Electric vehicles are to be found upon the stand of Mr. Jeantaud. There is first of all an example of his now well known cab, with its store of accumulators carried in a large box in front. The driver's seat is placed, as in the case of an ordinary hansom cab, high up at the back of the car. A great convenience is the shaded electric lamp throwing its light directly on to a voltmeter, so permitting an easy reading of the latter being made at night. Wheel steering is employed. Another car here shown is a phaeton, with hood and small "spider" seat behind. The wheel steering attached to this carriage is of the inclined type. A handsome Victoria is also exhibited, and the fourth and last car upon the stand is a small voiturette in blue, white, and gold. The exact purpose of this carriage is doubtful, for unless at a carnival or some similar festivity

A CORNER OF THE AUTOMOBILE SECTION AT THE CHAMP DE MARS.

Cliché de

(Le Chauffeur.

with a leather driving belt, which is extended by means of a lever placed conveniently before the rider. This belt drives on to two large pulleys, which give plenty of adherence and avoid slipping. The motor can be entirely disconnected when desired, and consequently the rider can at will pedal his machine as in the case of an ordinary bicycle. The maximum speed obtainable is 50 kilomètres per hour, while the constructors state that with the lower gear all hills can be ascended without pedalling at an average speed of 15 kilomètres per hour. Electric ignition is employed, a switch in the left handle rendering the cutting off of the current very easy. A trailing car or an "avant-train" can readily be attached to the frame of the bicycle. The motor is high speeded, running from 1,400 to 2,000 revolutions per minute, and it is so excellently attached that but very little vibration is conveyed to the frame. The carburettor is of a special type, and has been found to be very economical. The machine weighs some 35 kilogrammes, and the two-speeded type

the ordinary man would not care to mount so toy-like a vehicle.

The Société Européenne d'Automobiles, of Paris, exhibit a couple of steam-cars, each with seating capacity for four persons. Carried at the rear of the vehicles the engines are of 12 h.p., and are fed from water-tube boilers. Ordinary petroleum is used as fuel. The driving is performed through the medium of ordinary chains on to the rear wheels, the maximum speed obtainable being 45 kilomètres. The makers maintain that their boiler but seldom requires attention, the deposit made being infinitesimal. Wheel steering is fitted to both vehicles.

Among the voiturettes, that shown by M. Deschamps, of 31, Rue St. Augustin, Paris, is sure to attract some attention. The two-cylinder V type of petrol motor with which it is fitted is carried on the fore part of the car, and develops four horse-power effective. Three speeds varying from 5 to 45 kilomètres per hour are obtained through the medium of a conveniently placed lever.

The inclined wheel steering possesses a movable pillar, which in its forward position puts the motor into gear with the car. Pulled back it disconnects and causes the engine to run light. The weight of this little vehicle, which, by the way, is known as the "Excelsior," is 180 kilogrammes.

A couple of pretty little voituresses are exhibited by Messrs. Wehrle and Godard-Desmarest, of Neuilly-sur-Seine. The aluminium carriage body is carried on two C springs, and from practical experience I know the running to be very easy. Either the $3\frac{1}{2}$ h.p. De Dion or the new water-cooled Aster can be fitted to the frame as desired by the client. Three forward speeds and one reverse are obtained by the cog gearing contained in an aluminium case beneath the body of the vehicle, the speeds usually fitted being 10, 20, and 35 kilometres per hour. A friction clutch permits of all intermediate speeds being attained. The car is fitted with wooden wheels and the hubs are of bronze. A couple of brakes, one hand and one pedal, are employed.

Among the provincial firms showing is Messrs. Delaugère and Co., of Orléans, who are the makers of the Romain motor already illustrated in these columns. Built on the Otto cycle this engine is at present constructed in three sizes, viz, $2\frac{1}{2}$, 3, and $4\frac{1}{2}$ h.p.,

the two larger types being air or water-cooled at the customer's option. The makers claim that by means of a special disposition of the induction and exhaust valves in the body of the cylinder the return of the hot gases is prevented, and that considerable aid to the cool running of the engine is thus secured. In the case of the air cooled motors the cylinder head is provided with very prominent and vertically cut ribs, assuring perfect cooling. The ignition is electric. The motor is displayed fitted to three types of automobiles, these being a tricycle, a quadricycle, and a voituressette. This latter carries the engine in front and drives through the medium of cog-gearing. Three speeds are provided, and the water circulation and efficient cooling are secured by water circulation, pumps, and radiator.

(To be continued.)

THE partnership existing between G. D. Barnes and W. J. Colville, trading as the Middlesex Motor Carriage Company, at Walm Lane, Willesden Green, London, has been dissolved.

THERE were thirty-nine motor-carriages in line in Bridgeport's automobile parade on July 4. The silver loving cup offered by Mr. Griffin for the best decorated carriage was won by the Misses Emma G. Riker and A. M. Kennedy, of Bridgeport, U.S.A., who drove a Locomobile car.

THE Cooke Locomotive and Machine Co., of Paterson, N.J., U.S.A., are building a heavy steam-wagon under the Thornycroft patents, from drawings sent from England. We believe, states the *Horseless Age*, it is the only one of its kind under construction in the United States. It will have a 25-h.p. engine and water tube boilers, carrying 200lbs. pressure.

THE IRISH MOTOR TOUR.

(From Our Own Correspondent.)

THE further journeyings in Kerry of the two Daimlers driven by Messrs. Meeredy and Colohan are furnishing some interesting data on the possibilities of motor-vehicles in the multitude of circumstances which arise in extended touring through hilly countries. Kerry contains the highest mountains in Ireland, and a goodly supply of lesser heights which give the most adventurous driver quite as much variety in gradient as he is likely to need. The beautiful scenery is a compensation for the hilliness of the routes, whilst the surface is excellent. I think Kerry is a paradise for good cars, provided with adequately powerful engines, and driven by men who have perfect control over them. With weak engines and mechanism unable to stand sudden and powerful strains, a tour in such a place would indeed be a ghastly farce, and expensive withal, for repairs are unknown and railway accommodation is scarce. We have to go equipped as if in a strange land. The railway companies absolutely refuse to carry petrol, as do the steamer companies, and our only course was to get supplies by canal to a

point on the Shannon and carry thither a quantity sufficient to do us for several hundred miles. Besides, we have a full complement of passengers, and considerable luggage.

Thus loaded, we had, on July 15th, journeyed sixty-eight miles from Killaloe, *via* Limerick, to Listowel in Kerry, over a fairly hilly road and through glorious scenery along the Shannon. On

the 16th we made a forty-one miles trip from Listowel, *via* Tralee, to Killarney, getting really in amongst the mountains and having some stiff climbs, alternated with glorious rushes, the engines running free. Our biggest task was on the 18th inst., when we mounted the hilly road which leads from the Killarney lakes up over the hills to Kenmare. There are eight miles of a terribly winding road, the average grade of which is one in twenty. At numerous parts the gradient is as severe as one in six. The road is very narrow, and overhangs precipitous heights at many points. A sharp look-out has to be kept for descending cyclists and coaches, which often sweep round at almost uncontrollable speeds.

The Daimlers mounted in splendid style. Only at one point had we to shed a passenger, and then it was as a matter of extra caution, for the engine on its fourth speed was strongly cutting out at the time, and we had a big reserve of power to call on. The climb amply repays for the strain, as from this road a series of the most magnificent views of Killarney are obtained, and the route itself, running through beautiful glades and woods, is a constant pleasure to the appreciative lover of Nature.

Topping the crest of the last bit of up grade we swung out on the free, the engines out of gear. It was a magnificent coast of five miles, and but for the sharp corners we could have slipped along at terrific pace. As it was we did a nice twenty-five, and

THE CHAPELLE AND CHEVALLIER MOTOR-BICYCLE.

found it wildly exciting when there were cows and coaches to be negotiated round double S bends. We had ample opportunity of testing the capabilities of our brakes in cases where their failure meant somebody going down to Killarney by the vertical aerial route; merely a matter of a few hundred feet. However, we kept faithfully to the miculim, and found the incidents exhilarating enough. Beyond Kenmare we had Sneem Pass to negotiate, and this necessitated some more miles of stiff collar work for the cars, though not at all so severe as the ascent from Killarney. The ensuing run down proved very enjoyable. Indeed, so far we have found that hill-climbing has its attractions owing to the excellent going generally found on the other side of the slope.

Hitherto we had occupied the main coach route and had no trouble as to road room. But at Cahirdaniel our itinerary led us on to a very narrow by-road of fearfully tricky gradient. The windings were bewildering, and many of the ascents sharp and sudden. To crown all a most treacherous slime tried our stability severely. It was one of the nastiest roads a car could be taken over, and the consequence of any error would have been most serious, as deep bogs bordered the way. However, we reached our destination without trouble, our cars once more showing what excellent road machines they are. Our total distance for the first four days comes to 273 miles, or an average of 68 miles a day.

CORRESPONDENCE.

THE 1,000-MILE TRIAL.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Your correspondent "Purchaser" in to-day's issue should have invested the humble 1d. per week in buying the *Motor-Car Journal*, which throughout the 1,000-mile Trial gave a most reliable account of the doings of all the competing cars.

The information contained therein, coupled with what I had gleaned by inquiry, enabled me to decide upon placing an order for a "Star" car, notwithstanding the fact of this car having a mishap during the trial, which your *Journal* duly recorded. I would respectfully advise "Purchaser" to visit the Star Works at Wolverhampton, when an ocular demonstration of the excellent workmanship and finish of the motor throughout would quickly enable him to make up his mind.

Yours truly,

99, Walter Road, Swansea,
July 21st, 1900.

A. A. JONES.

INCREASE OF PRICES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—As another epidemic of rising prices seems to have set in among the makers, will anyone kindly explain why the increased demand for cars should be given as an excuse to raise prices? In all my connection with the business world increased demand tends to lower rates. I can only suppose that the motor industry is regulated by the rules of contrary. I hope the public will not buy at increased prices under these conditions.

Yours truly,

Clerkenwell, E.C.,
July 20th, 1900.

W. T. W.

MOTOR-CYCLE TOURING.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Would some of your readers who have toured on motor cycles, or who have had them with them when staying away from home, be good enough to state whether they often or usually have difficulty in finding suitable quarters for their machines? Whether the hotels or inns in many cases have separate lock-up accommodation for them, and, if not, whether there is not considerable risk of them being tampered with? Is there any special channel through which one who is not "in the know" may ascertain in what towns and at what houses he is most likely to find suitable accommodation? I am deterred

from using my motor-quad, except for rides from and back to my residence, through a feeling that I should experience a good deal of trouble and perhaps annoyance in connection with the housing and cleaning of the machine.

Yours truly,

Bolton, July 23rd, 1900.

"SAMUR."

P.S.—I have copies of such petrol and hotel lists as I have as yet come across.

MOTOR-BICYCLES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Will you permit me through your columns to offer a word of advice in the matter of applying the brake on motor-bicycles? A few nights ago a friend of mine, whilst riding a motor-bicycle near Kenilworth, met with a serious accident through applying his brake too suddenly. It appears he was going down a hill at about sixteen miles an hour as a wagon-load of hay was coming in the opposite direction. Just before reaching the first horse the animal began to prance, when my friend applied his brake, and in doing so he naturally swerved, and he and the machine rolled underneath the horses' feet. Although terribly bruised, fortunately no bones were broken, but the motor-bicycle will never be ridden again.

By the way, some time ago one of your correspondents wrote respecting the merits of motor-bicycles. Being an old cycle racer, I at that time thought that a motor fixed to a bicycle would be simply perfection; but I would advise anyone that thinks of purchasing this type of machine to take *Punch's* advice to those about to marry—"Don't." I notice week by week many firms trying to introduce this type of machine, and it is quite amusing to notice the many different positions where the motors are fixed—some in front, some right behind, others fixed on the side of back forks, whilst others take the place of the bottom bracket; yet each maker claims his to be the best. The latest one is a motor fixed inside the back wheel. I notice, however, that one has to take the wheel to pieces to grind the valves in!

Yours truly,

Brighton Villa,

F. JACKSON.

Kenilworth, July 26th, 1900.

A PROPOSED BIRMINGHAM AUTOMOBILE CLUB.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Is it not about time we had an Automobile Club for Birmingham district? Personally, I should be glad to do anything to assist in the promotion of the same.

Yours truly,

July 24th, 1900.

"FORWARD."

THE Auto-Club Verbano is the name of a new club which has just been formed at Stresa (Lake Maggiore), Italy.

THE American Express Company has determined to make a trial of electric vehicles for delivery purposes, and with this object a Woods delivery wagon has been sent to the Milwaukee, Wis., office.

Two 6-h.p. heavy oil vehicles are being prepared for service as cabs in London by Messrs. Roots and Venables, of Westminster Bridge Road, S.E., who are in communication with the Chief Commissioner of Police with reference to the necessary licences.

IN a recent list of new Illinois incorporations was the following:—"The name of the An-T-Phat Company of Chicago is changed to the Chicago Automobile Company." We do not see the connection. Perhaps some humorist can supply the missing link.

It has at last been decided in France that automobile is masculine, and that it is correct to say "un automobile." The *Vélo* says that the Académie-Française has decided by vote that in future "automobile" should be masculine, the idea apparently being that it is an adjective qualifying the word "vehicule," understood.

THE CLEVELAND ELECTRIC CAR.

THE other day we had an opportunity of inspecting a new electrical car built by the Cleveland Machine Screw Company of Cleveland, Ohio, and lately introduced into this country by Mr. C. Eagle-Bott, of Donington House, Norfolk Street, Strand, W.C. The car, of which an illustration is given herewith in Fig. 1, takes the form of a two-seated hooded Stanhope. The frame is built up of solid steel rods and tubing; two "reach rods" extend from the front axle

FIG. 1.—GENERAL VIEW OF THE CLEVELAND ELECTRIC CAR.

and connect with spring-supporting ball-bearing housings on the back axle near each wheel. The attachment at these points is by means of universal joints, allowing full freedom of movement on uneven roads, the plate springs at the front also working on a central oscillating joint with a similar object.

The electro-motor is of the bi-polar type; it is of 3 h.p. nominal, but has a large overload capacity. It is suspended in the centre of the frame immediately in front of the rear axle by a hinged joint on the latter and by trusses connected with the frame. The motor shaft carries a pinion which meshes with a spur wheel on an intermediary shaft, from which the power is transmitted to a spur wheel surrounding the differential gear on the rear axle. The whole of the motor and transmission gear is entirely enclosed. A mechanical two-speed gear is mounted on the intermediary shaft, this being brought into use when unusually steep hills are to be mounted.

Coming now to the accumulators, this consists of forty cells, the plates being of the Faure pasted type. The cells are of the seven-plate kind, and are carried in ebonite boxes. The positive plates are enclosed in a special fibrous envelope, which, while said to be unaffected by the acid, prevents the disintegration of the active material from the plates. The latter are further separated by means of plates of perforated and corrugated hard rubber. The battery has a capacity, at 24 ampères, of 120 ampère-hours, and will, it is claimed, run the car a distance of 75 miles over ordinary roads at an average speed of 11 miles per hour on one charge. The weight of the forty-cell battery is given as 880lb. The battery is adapted to be charged in position, but can be withdrawn if necessary. Every part of it is readily accessible, the top and end of the rear portion of the body being made to lift up; the seat can also be lifted off if necessary.

A feature of the car is the combination steering gear and speed controller, the latter being arranged to give three speeds forward and reverse. The controller of the Cleveland vehicle is novel and entirely original, all the actions of controlling being simplified by the use of a single handle. This handle not only serves for the steering of the vehicle, but puts on or shuts off the power, applies the brake, and reverses the direction of motion,

and also the vehicle may be securely locked while the owner leaves it for any length of time. The direction of the vehicle is controlled by lateral movement of the lever, the vehicle going in any direction to which the handle is pointed or aimed. Depressing the handle from notch to notch increases the speed, and pulling up the handle, as one would draw in the reins in case of emergency, instantly turns off the current and applies a hand brake on the intermediate shaft. This hand brake is adapted to work with the car running either forward or backward. The intensity of the brakes is increased as the handle is further raised. When the speed has been reduced, by again lowering the handle any of the speed notches can be readily picked up, the speed and brake being always under instant control, one hand only being engaged. The controlling handle is made either to stay where placed or is self-raising to the brake position to suit the fancy of the owner. The controlling handle lying nearly horizontal, the "aiming" action in steering completes the simplicity of the operation. The controlling head, which is shown in Fig. 2, is supplied with an indicator showing at all times the position of the controlling cylinder. The steering and controlling handle may readily be raised to an upright position for the convenience of occupants, especially for getting in and out on the driver's side. A small plug is provided in the steering head, the removal of which, when the car is left, prevents it being operated except by the driver. The controller and current-manipulating switches are located below the floor, and in front of the batteries, this, it is claimed, avoiding hydrogen detonation.

Special attention has been given to the question of rendering the vehicle dirigible, to the easy control of the guiding mechanism, particularly in regard to meeting obstructions, so that the mechanism should not be deranged, or the vehicle thrown out

FIG. 2.—VIEW OF COMBINATION STEERING AND SPEED-CONTROL HANDLE.

of its course. After exhaustive experiments the Cleveland Company claim to have succeeded in finding a method of attaching the front wheels which seems to have overcome all difficulties. In tests designed to thoroughly demonstrate the practical operation of the device, and especially to compare it with the one ordinarily used, it was found that the amount of side thrust admitted to

the guiding handle was practically in proportion to the leverage measured by the distance between the steering axis and the plane of the wheel, at the highest point of the interception of the obstruction. The front or steering wheels are not mounted on the usual short vertical pivots, but the steering axis stands oblique, and is made to intercept the plane of the wheel up from the bottom or ground line, where obstructions are encountered, and where they may be met "head on" and therefore entirely neutralised, giving, it is stated, no tendency to deflection in either direction. It is also claimed that the arrangement gives the vehicle a quality of self-centring, or running straight-forward, hands off. The wheels when turned in the act of guiding describe a conic section, the lowest point of which is the straight-forward running position. Another peculiar feature is that in this action each wheel is entirely independent of the other, throwing no stress upon the connections or guiding rods.

A foot pedal operates tire-brakes on the rear wheel, and when these are applied the current is automatically switched off, and cannot be put on again until the brakes are released. In fact, when either brake system is in operation the current is automatically cut off, and cannot be again established until the controller is open circuited.

The front axle runs on ball bearings; the rear axle is not split as usual, but is built up of two axles extending one into the other for a length of about 12in. The joint which is in the centre is of peculiar construction, rendering the axle self-supporting. The headlight or front central lamp is mounted on the fore-carriage in such a way that it turns with the front wheels. The car is fitted with solid rubber tires, wood wheels, and weighs complete about 19cwt. It can attain a top speed of twenty miles per hour. The Cleveland Company are also building a 5 h.p. car, and also a small "runabout," having a battery whose capacity on one charge is from twenty-two to twenty-five miles.

THE FRENCH AUTOMOBILE CLUB'S FÊTES.

(From Our Own Correspondent.)

AS I stated some time ago in these columns, the dates originally selected for the two fêtes given by the Automobile Club of France in honour of the Commissioners of the Exhibition were July 18th and 19th, but by reason of the former date clashing with the visit of the Commissioners to the naval manœuvres at Cherbourg, it was found necessary to make a change, and the fêtes therefore actually took place on Thursday, the 19th, and Saturday, the 21st instant. These festivities were the more noteworthy on account of the new theatre being utilised for the first time. With a seating accommodation for eight hundred persons this beautiful *salle* is the most remarkable of all the magnificent rooms in the club house. It is situated on the first floor and directly above the *garage*, access to it being by way of the member's dining room or by a new staircase which mounts from the courtyard. The theatre consists of a ground floor and a balcony, the seats in every part of the house being of the most luxurious character and upholstered in yellow leather. The walls and ceiling are of a snowy whiteness and carry a number of bas-reliefs dealing with automobilism. The drop curtain is of yellow velvet, and handsome curtains of the same material decorate the various entrances. Handsome as the *salle* is in the daytime the effect by night is really wonderful, for the electric light installation is the work of an artist. Hidden away behind the two cornices, the one actually in the ceiling and the other almost at the top of the walls, are two rows of lights running entirely round the hall, giving a marvellously subdued light, and one changed at will from a warm rich rose to a golden yellow. Large arc lamps are placed against the walls, while around the underside of the balcony are arranged a number of dark coloured lights, which give a wonderfully pretty effect to the appearance of the theatre.

On Thursday evening this installation was not seen to advantage, for almost immediately after the numerous company

had been admitted into the hall the light failed entirely and it was only by very occasional fits and starts that it made its reappearance. As the visitors had been previously warned of such a possibility no panic or undue excitement occurred and everybody waited patiently for further developments. These came in the shape of an assorted collection of candles, lamps, and lanterns gathered together from every part of the club house, and by their united efforts sufficient light was thrown upon the stage to permit of the programme being proceeded with. By way of limo lights three large acetylene lamps, borrowed from cars in the *garage*, were utilised, and the sight of certain well-known club men manipulating these miniature lighthouses from the balcony will not readily be forgotten. This *contre-temps* was undoubtedly very annoying to the organisers of the fête, but it amused the audience vastly, and but few left the theatre until the curtain went down on the last number of the programme at two o'clock in the morning. The light on Saturday evening behaved itself, however, and the visitors were treated to a delightful soirée. Commencing with a selection by M. Bosc's capital orchestra, the programme's second item was the *Capricioso* of Mendelssohn, executed by Mlle. Picot. Then followed a one-act piece by MM. Eugène Maas and Paul Delay, the three rôles being played by Mlles. Mylo d'Arcyille and Grimault and M. André Royer. This item was succeeded by a series of ancient dances executed by Mlles. Christine Booss and Antonine Meunier, of the Opéra, who in turn gave way to Mlle. Christine Kerf and M. Viscussi, of the Palace de la Danse. The Spanish dances executed by the latter performers were especially good, and were greatly appreciated.

A pantomime entitled "Noir et Blanc" was the next item on the programme, and it was excellently played by Mlles. Zambelli, L. Mante, and Torri, of the Opéra. The ballet of the Palais de l'Optique then gave an exhibition of their phosphorescent dances, but it was not until after the conclusion of their performance and the lights had been again turned on that one saw anything whatever of the fair dancers. The second part of the programme consisted of a review by M. Jacques Redelsperger, with music by M. A. Bosc, entitled "Le Jeu de l'Auto." The review dealt principally with M. Lépine's regulations and the cyclist-policeman, the scene of operations being the garden terrace of the club. The cast was as follows:—The Muse, Mlle. Rollys; The Automobile Club, Mlle. Germaine Gallois; Stellite, Mlle. Paulette Filliaux; An Urchin, Mlle. Mylo d'Arcyille; Carburette, Mlle. C. Médal; An Englishwoman, Mlle. Louise Bignon; Pétrole, Mlle. Grimault; A Cyclist-policeman, Mr. Hirsch; An Englishman, Mr. Fordyce.

Rejoicing in bright and tuneful music and several witty songs, the review scored a great success, M. Lépine, who was himself present, being especially amused by the humorous caricature of his creation—the cyclist-policeman. In addition to the principal members of the Club and nearly all the Commissioners of the Exhibition, there were also present the Maharajah of Kapurthala, Prince della Rocca, Comtesse Cahen d'Anvers, Baronne de Bélinay, Comtesse A. de Golstein, Comtesse Cognard, Vicomtesse A. de Contades, Marquis de Gouvello, Comte de Nion, and many other visitors too numerous to mention.

THE local authorities of Newark, N.Y., have decided that an automobile is subject to the same law as a traction engine, and should be preceded by a watchman an eighth of a mile ahead.

THE President of the Bordeaux Automobile Club has been asked by the local authorities to appoint a committee to draw up regulations for cycle and motor-car traffic in the Bordeaux district.

THE Overman Automobile Company has been incorporated in New York, under New Jersey laws, with a capital of £50,000, to construct steam cars on the system of Mr. A. H. Overman, late of the Overman Wheel Company.

WE learn from Novara, Italy, that a steam road service has just been established between that town and Robbia. Similar services between other small towns in the district are contemplated.

THE ST. LOUIS MOTOR-VEHICLES.

AN AMERICAN CONCERN which claims to have got beyond the experimental stage is the St. Louis Motor-Carriage Company, of Vandeventer Avenue, St. Louis. At present a light two-seated "runabout," a park "phaetonette," a stanhope with hood, a light delivery wagon and a covered van are being turned out from their works, which are said to be well-equipped, the assembling department being under the direction of Mr. Charles Bates, who, according to their catalogue, was formerly at the Motor Manufacturing Company's works in Coventry.

Of the vehicles above mentioned we illustrate two, Fig. 1 showing the two-seated phaetonette, and Fig. 2 the light delivery wagon. The carriage weighs complete 9 cwt., and is propelled by a two-cylinder horizontal motor of 6-h.p. The cylinders are made of cast iron, and are of 4½-in. bore and 6-in. stroke. The cranks are balanced at 180 deg. The usual water jackets are employed, the circulation being by gravity, while the ignition is electrical. The engine is located about the centre of the frame. Its pull is taken by an adjustable arm swinging between the engine shaft bearing and the sprocket shaft bearing outside the gear box. Tilting of this gear box is said to allow perfect freedom to the rise and fall of the rear axle on bad roads, and at the same time the swinging arm secures perfect chain adjustment at all times. Two speeds forward and one reverse motion are provided, the power of the engine being transmitted by a single chain to a small countershaft parallel and close to the rear axle.

FIG. 1.—GENERAL VIEW OF TWO-SEATED PHAETONETTE.

The countershaft carries a series of pinions enclosed in an oil-containing gear case, any one of which can be made to mesh with corresponding pinions on the rear axle. One friction clutch, working on the engine shaft, only is employed. When the vehicle is standing the gears are disconnected, a catch preventing the engagement of the clutch unless the gears are in perfect mesh, thus preventing, it is claimed, the stripping of the gears. The rear axle is in one piece, not being cut where the differential is applied, as is usually the case. One road-wheel is driven by the axle, the other by a hollow shaft slipped over the axle. The carriage, which is geared up to a maximum speed of eighteen miles per hour, is controlled by two levers at the right-hand side of the vehicle. One throws in the clutch, and when the clutch is thrown out applies the brake; the other shifts the gears. The speed of the motor is regulated by a foot-pedal. The exhaust silencing device is described as being very simple. It consists of a cylinder about 2 ft. long and 6 in. in diameter, placed underneath the body, and containing a number of steel plates full of small holes. A row of larger holes in the centre of the outer circumference allows for the final escape of the exhaust. Steering is controlled by the usual tiller lever, acting on the front wheels. The engines, running gear, etc., are mounted on an angle steel frame. Every portion of the engine and gearing is easily accessible, and, if necessary, the body of the carriage may be

taken off by removing a few bolts. The wheels are of wood or steel as desired, the wooden wheels having metal hubs and steel rims. Three-inch pneumatic tires or 1½-in. solid rubber tires are fitted. The petrol tank has a capacity sufficient for a run of 100 miles, while the water tank, which is concealed in the rear, holds ten gallons.

FIG. 2.—GENERAL VIEW OF LIGHT DELIVERY WAGON.

The light delivery wagon (Fig. 2) is fitted with a 6-h.p. two-cylinder motor, the transmission being identical with that in the car above described, the maximum speed, however, being only twelve miles per hour, at which it will carry a load of about 12 cwt., and mount gradients of 15 per cent. at a good speed. As will be seen, the car is fitted with wooden wheels and solid rubber tires.

THE New Dorp Beach hotel at New Dorp, Staten Island, U.S.A., is an up-to-date establishment, for in addition to a bicycle shed it announces that it has an electric charging station for automobiles.

THE London Motor Company, Ltd., has been registered with a capital of £30,000 to carry on the businesses of motor and other vehicle manufacturers and merchants, oil merchants, etc. The first directors are Messrs. S. F. St. J. Steadman, W. Dangerfield, and D. E. Cardinall.

AT the recent automobile congress at Padua, Italy, the organisation of a tour round Italy was proposed. The itinerary will be Turin, Alexandria, Genoa, Spezia, Pisa, Leghorn, Rome, Perugia, Florence, Bologna, Padua, Verona, Brescia, and Milan. The total length is 1,500 kilometres.

MR. ROLAND R. CONKLIN, of the North American Trust Company, New York, has planned an automobile trip with a 10-h.p. petrol car through France, Spain, Austria, Bavaria, and England. The party will include, besides Mr. Conklin's family, a Frenchman to run the machine and act as interpreter. The party has already left New York for Europe.

LOOKING in at the Automobile Palace on Holborn Viaduct, E.C., the other afternoon, Mr. Friswell showed us a number of new cars, including Brierre and Clement-Panhard voiturettes, he has now in stock. We were also just in time to see a novelty he picked up in Paris in the shape of a two-seated dog-cart—a little car arranged to seat two persons sitting *dos-à-dos*. It is propelled by a 2½ h.p. air-cooled Aster motor located under a bonnet in the fore part of a tubular frame. Two speeds are available, a single belt conveying the power to a short countershaft behind the rear axle, spur wheels connecting the latter. With inclined wheel steering and cycle-type wheels shod with pneumatic tires, the miniature car is said to run extremely well.

MOTOR-CARS ON THE CONTINENT.

(From Our Own Correspondent.)

Racing at Turin.

THE Automobile Club de Nice has, says the *Velo*, come to an agreement with the Automobile Club of Italy regarding the programme of the automobile races which are to be held at Turin next April. The Nice automobilists will go in a large party, and after the Turin races will make a tour of Italy, which will last till May 9, the itinerary being as follows: Turin, Milan, Padua, Venice, Bologna, Florence, Rome, Pisa, and Genoa.

The Durkopp Car.

THE accompanying illustration shows a light petrol car, capable of seating two or three persons, built by the Bielefelder Maschinenfabrik Gesellschaft (Durkopp), of Bielefeld, Germany. The motor is located on the rear of the frame; it is of 3 h.p., and is fitted with water-jacket and electric ignition. Two speeds are provided, the engine driving the rear axle direct by spur-gearing. There are two sets of gears, either pair of which can be made to transmit the power by means of a friction clutch.

The frame is of special tubular construction, and the wheels are of the cycle type, shod with pneumatic tires. Ample brake power is provided, while the steering is of the Benz type. All the working parts run in oil, the crank and gear cases being of aluminium. The car can, it is stated, attain a speed of 30 kilometres (18½ miles) per hour.

The Brescia Meeting.

At a meeting of the organising committee, held on the evening of Wednesday, July 18th, it was decided to hold this year's automobile fêtes at Brescia during the early part of September, the exact dates selected being as follows:—September 6th to 10th, exhibition of automobiles; September 8th, automobile races on the track; September 10th, automobile road race. A congress will also be held at Brescia at the same time as the fêtes, and will doubtless bring together a gathering thoroughly representative of Italian automobilism. The president of the Milan Automobile Club has accepted the presidency of the committee of organisation, and under his able guidance the arrangements will assuredly be excellent.

A Tour of France.

A MOTOR-CYCLE ride of exceptional length has just been accomplished by the well-known racing man Joyeux, mounted on a "Perfecta" tricycle fitted with a Soncin engine. The distance was no less than 4,000 kilometres, or 2,500 miles, and in spite of the tropical heat experienced by him during the greater portion of the trip Joyeux only took eleven days nineteen hours to make the entire round. Last year Joyeux accomplished

the same tour in fourteen days and twelve hours, so his new performance beats the previous record by two days seventeen hours, a truly respectable margin. The record man has now departed to his home at Castillonès, to enjoy a well-earned rest and banish motor-cycles from his sight for a week or two. Personally, I should have no desire to make so long a trip in so short a time and under such trying atmospherical conditions as those experienced by Joyeux. The very thought of it causes me to mentally picture saddle soreness and a dozen other objectionable things.

Automobile Excursions in Algeria and Tunis.

Two large automobile excursions are being organised for October and February next, one in Tunis and the other in Algeria. The "Caravane Algérienne" is being organised by *La France Automobile* for February, and will be so arranged that automobilists can be back at Nice for the "Grande Semaine." It will last for seven days, during which the itinerary will be from Algiers to Tizi Ouzou, Bougie, Aumale, Hamman Rhira, and to various places worth visiting in the vicinity. Altogether 900 kilometres will be covered, and there may probably be a race from Bougie to Aumale. The second excursion mentioned, which is being organised by M. G. de Meaulne, will last a month. The automobilists will leave Marseilles at the end of October for Tunis, whence they will go to Kairouan, Sfax and Gabès. After three weeks passed in Tunis the excursionists will return *via* Algeria.

At Vincennes.

THE authorities would at last appear to realise the serious condition of affairs at the Vincennes annexe of the Paris Exhibition, for, as the result of the urgent representations made by the exhibitors and the *concessionnaires*, active steps are now being taken to remedy matters. That this tardy attempt to render the exhibition more attractive will have a considerable effect upon the attendance of visitors cannot be doubted, but it is equally certain that it is now too late in the day to make of the Vincennes show a real success. People will not trail right out into the suburbs to see an exhibition, especially when on all sides they hear nothing but discouraging reports. The show is too straggling, the buildings being scattered about over a very large area, thus making it a veritable labour to inspect the objects exhibited. Many of the police and attendants themselves, who are on duty within the grounds, do not know the whereabouts of the various sections, so the difficulty experienced by a stranger in finding his way may well be imagined. The present intention of the authorities is to make the month of August a special month of fêtes, and to this end preparations are going rapidly forward. Commencing on Monday, August 6th, and continuing until the following Saturday, there will be held an automobile cab competition, and on the Thursday of the same week a grand sporting fête will take place on the track running around the lake Daumesnil. A week later, or to be exact, from Monday, August 13th, to Saturday, August 18th, a competition for voiturettes will be decided, and this event is certain to secure an excellent entry. Thursday, the 23rd proximo, will see a series of motor boat competitions on the lake Daumesnil, for which already some ten engagements have been received. It is also the intention of M. Georges Longuemare, who is occupying himself very actively on behalf of the exhibitors, to interview the Committee of Amateurism at an early date, in order to discuss the practicability of organising an amateur meeting on the new municipal track.

MR. W. A. Taylor, of the Coventry Motor Company, Ltd., has just patented a new motion dispensing with transmission gears. We hope to be in a position to fully describe and illustrate the device in a few weeks time.

COLUMBIA UNIVERSITY, N.Y., U.S.A., announces a course in "Traction Engines and Carriages," which will treat the subjects of self-propelling road engines and automobile carriages. Prof. Frederick Remsen Hutton will conduct the new course.

THE SIRENE VOITURETTE.

IN our issue of April 27th last we gave a general illustration of the "Sirene" voiturette made by Messrs. Fernandez and Company, of Paris, and lately introduced into this country by Mr. F. F. Wellington, of Regent's Park, N.W. We are now able to give some additional particulars and illustrations of the little car. First of all it may be mentioned that the car is built low, the body, which has seating accommodation for two persons, being supported on a spring-suspended tubular frame.

FIG. 1.—PLAN OF SIRENE VOITURETTE.

A feature of the car is the petrol-motor by means of which it is propelled. This is of the two-cylinder inclined type, Fig. 2, the piston rods working on to a single crank shaft. It is fitted with electric ignition and radial fins for air-cooling, and is said to develop from $3\frac{1}{2}$ h.p. to 4 h.p. Three speeds forward (10, 15, and 32 kilomètres per hour) and a reverse motion are available, any intermediary speed being

FIG. 2.—PART-SECTIONAL ELEVATION OF MOTOR.

obtained by the variation of the electrical ignition. Referring to the plan (Fig. 1) it will be seen that the motor *M* is located in the fore part of the frame, where air has free access to the radial fins of the cylinders. The motor shaft carries at its end one half of the clutch *E* operated by a foot pedal. The variable speed

gear is very much on the lines of the Panhard, the box *F* containing three pairs of spur wheels, any one pair of which can be brought into mesh at a time. The reverse motion is obtained by the interposition of a small pinion between the gear wheels giving the slow speed. From the gear box the power is transmitted direct to the gear axle *N* through the universally-jointed transverse shaft *H* and the bevel gear *L*. Steering is controlled by an inclined hand wheel, on the standard of which are fitted the taps connected with the carburation and sparking. The variable gear is manoeuvred by a lever working in a sector at the side of the steering standard. A foot pedal operates a band brake on the transverse shaft, while there are band brakes on the hubs of each of the rear wheels controlled by a hand lever. The car complete weighs about 6 cwt. and can attain a speed of 40 kilomètres per hour on the level.

THE UPTON VARIABLE SPEED GEAR,

A NEW variable speed gear, giving two speeds forward and reverse motion, has lately been put on the market by the Upton Machine Company, of New York. From the external appearance it will readily be noted that the transmission is accomplished through the medium of a system of spur gearing. A concise explanation is perhaps best given by figuratively taking it to pieces and describing each piece in detail. To commence with the shaft: it extends through the centre of the gearing, and is made of one piece only. At either end it may be connected by half coupling directly to the motor shaft, or as an intermediate, by means of chains or spur gearing. Upon the transmission shaft, and an integral part of it, are the two pinion gears which are the direct drivers.

The disc furthest to the left rotates loosely upon the shaft, and by means of three studs placed equidistant from the hub acts as the support of three small spur gears. These gears are in mesh with one of the pinion gears and an internal gear. By compressing the brake the disc is rigidly held and the movement of the pinion being imparted to and continued by the three spur gears, causes a reverse movement of the annular rack surrounding them. The rack is firmly fastened to a metal ring, a section of which would show a Z-shaped forma-

tion top and bottom; and the internal gear, being fastened to and enclosed by one side of the ring, the other side is used as a support for the casing holding the second annular rack, which is also flanged for a brake band, the casting revolving loosely on its support. Compression of the brake in this case holds the rack, and as the support of the rack also carries three spur gears in mesh both with the rack and the other central pinion, it will be seen that, the rack being held, the rotation of the pinion driver must be continued by the three spur gears, and the supporting studs around which the gears revolve, being not only attached to the Z or cone-shaped structure, but also to the flange which carries the chain sprocket; it will be seen that the movement of the three spur gears is coincident with the movement of the sprocket, and the slow speed ahead is produced. The purpose of the sprocket or spur gear, should one be substituted, is to effect the connection with the rear axle. Next to the sprocket is a friction clutch. By this clutch the mechanism, in its entirety, is locked to the shaft and the fast speed is obtained. Lubrication is accomplished by means of a special oiling device on one end of the shaft, which is made hollow for that purpose. The gear is made suitable for cars up to 4 or 5 h.p., and weighs only 35lb.

THE SCOTTISH AUTOMOBILE CLUB'S RUN.

THE first outing of this club, which is affiliated with the Automobile Club of Great Britain, took place on Thursday last week, when some eight or ten cars, with about forty members and friends, journeyed to the Highland Agricultural Society's great show, held this year at Stirling. Five carriages left St. Andrew's Square, Edinburgh, at 8.15 a.m. for Linlithgow, where it had been arranged to meet the Glasgow and West of Scotland contingent and have breakfast. Linlithgow was reached about 9.20, where three cars from the west had already put in an appearance along with Mr. Pullar, of Bridge of Allan, on his tricycle. Lord Kingsburgh, president of the club, had driven in from the Forth camp at Lochcote, bringing with him Mr. Stirling and party, whom they had picked up two miles out, Mr. Stirling's 8 h.p. Stirling-Napier having met with a slight mishap on the way. In endeavouring to give a wide berth to a couple of timber wagons, he had gone too close to the hedge, when the front wheel dropped into a deep rut, which could not be seen for the long grass, with the result the wheel was disabled. Ten minutes after the accident Lord Kingsburgh's car appeared and rendered useful service in conveying the party to Linlithgow. An excellent breakfast was partaken of, and brief speeches were made by the President and Mr. John McDonald, when Lord Kingsburgh gave an invitation to the club to visit his summer quarters at Auchterarder. The journey was resumed at 11 o'clock, and the outskirts of Stirling reached by the leading cars shortly after 12 o'clock. A halt was made at St. Ninians, in order to allow the other

MR. STIRLING'S 8 H.P. STIRLING-NAPIER ON THE ROAD NEAR DENNY.

cars to come up before entering Stirling. At 1 o'clock Mr. P. Drummond, on his De Dion tricycle, arrived and kindly acted as pilot for the club on the journey to the show ground, where the Highland Society had provided suitable accommodation for the cars. On two occasions during the afternoon, at the request of the directors, the vehicles paraded in the show ring, creating a vast amount of interest. Shortly before starting on the return journey, Mr. Stirling's *mécanicien* drove in with his 8 h.p. Stirling-Napier, a new front wheel having been procured for it from the Hamilton works. The following were among those who took part:—Lord Kingsburgh (Daimler wagonette), Dr. and Mrs. Turner (Delahaye victoria), Mr. John MacDonald, C.A. (Daimler dogcart), Mr. T. R. Outhwaite (Parisian-Daimler), Mr. and Mrs. Stirling (8 h.p. Stirling-Napier), Mr. J. D. Brimlow (Stirling-Daimler dogcart), Mr. John Naismith (Stirling-Daimler wagonette), Mr. Pullar (De Dion tricycle), Mr. P. Drummond (De Dion tricycle), Messrs. Ross and Sleight (Caledonian char-a-banc),

Mr. John Wilson, Liberton; Rev. J. Ferguson, Hamilton; Dr. Edwards, Glasgow; Dr. Sommerville, Bradford; J. Duncan,

MR. J. NAISMITH'S AND MR. J. D. BRIMLOW'S CARS LEAVING STIRLING FOR GLASGOW.

Glasgow; Mr. Newton, Secretary of the Scottish Automobile Club; etc.

THE Foye Hub Motor and Automobile Company has been incorporated in Jersey City, U.S.A., with a capital of £40,000.

AN automobile club has been organised at Buffalo, N.Y. The first club run will take place September 4th, and a parade is talked of.

BARON ARTHUR DE ROTHSCHILD has been elected one of the vice-presidents of the recently formed Motor Club de France, which has now over 500 members.

A CORRESPONDENT is seeking information as to the best kind of carburettor for use in connection with a motor of the Pennington type that has so far had gravity feed.

THE Motor Manufacturing Company are enquiring as to the whereabouts of a De Dion engine, No. 92, made by them and removed by some unknown person from their London showroom.

NEGOTIATIONS are in progress to place a large number of motor-omnibuses on the streets of St. Louis, U.S.A. It is reported that these vehicles will carry thirty passengers each, and that they will have the same gauge as the trolley-cars, so that they can run on the rails if desired.

THE Harrogate Athletic Sports are to be held on Bank Holiday, the 6th prox., in conjunction with the North of England Cyclists' meet and camp. The programme of events includes a two miles handicap motor-cycle race, open to machines of not more than 4 h.p., and carrying not more than two riders.

WE learn that Mr. Frank F. Wellington, of Regent's Park Road, N.W., is introducing and putting on the market a new German silver ignition tube for motor-cars to take the place of the platinum tubes which are now so expensive. These tubes will be found very useful to carry about in case of emergency, and their cost compares very favourably with that of platinum tubes.

THE Centre Steering Tractive Company, Ltd., has been registered with a capital of £1,000 to acquire from W. E. Carmont and A. C. Larking a patent for improved means of steering road vehicles, and to manufacture and deal in motor-tractives, motor and other vans and carriages, and all their component parts and accessories. The registered office is at 536, Mansion House Chambers, Queen Victoria Street, E.C.

THE RAOUVAL MOTOR-CARRIAGE.

ONE of the latest French engineering concerns to take up the construction of motor-carriages is the Société de Mécanique Industrielle d'Anzin, of Anzin Nord, one type of whose productions we are able to illustrate herewith in Figs. 1 to 6. The motive power is supplied by a two-cylinder vertical motor of the "Pygmée" type; it is capable of developing from 6 to 8 h.p., the speed ranging from 650 to 800 revolutions per minute, the cylinders being 110 mm. in diameter, by 150 mm. stroke.

The motor is located at *M* (Figs. 3 and 4) in the front part of the frame, with its shaft arranged longitudinally. The motor

FIG. 1.—GENERAL VIEW OF RAOUVAL CAR.

shaft *O* carries the fly-wheel *U*, which forms the female portion of the clutch, the male portion *U'* being loose on the shaft. The disc *U'* is connected by means of the coupling sleeve *F* with the variable-speed gear shaft. Three forward speeds and a reverse motion are provided. The speed-changing gear is enclosed in the case *K*, and comprises three spur-wheels gearing with corresponding pinions on a short intermediary shaft below and parallel to *O*. The reverse motion is obtained by means of a lever *L* (Fig. 3) acting on the bevel wheels *L'* *L'* on the differential countershaft *G*, the direction of running of the car depending on which of these

FIG. 2.—SECTIONAL VIEW OF VARIABLE-SPEED GEAR.—RAOUVAL CAR.

wheels is in gear with the bevel pinion *L* (Fig. 2). From this intermediary shaft, *G*, the power is conveyed through duplicate sets of sprockets and chains to the rear axle. To prevent any reverse motion to that desired a sort of free-wheel arrangement is introduced on the end (*P*, Fig. 2) of the variable-gear shaft *I*—a section of the clutch being given at the bottom of Fig. 2.

The control levers are located close to the steering pillar, *N*, controlling the variable speed gear and *L* the reverse motion. The mixture is controlled by a handle, *H*, in the centre of the steering wheel, connected with the valve of the carburettor by a steel cable. Steering is controlled by an inclined wheel; it is of the "progressive" type. The movement of the hand wheel *m* is transmitted by an eccentric pinion *k*, and a sector *h*—resulting in a progressive angular displacement—to a second shaft *g*, at the extremity of which is a lever *f*, the end of which is connected by an arm *e* to the rod *b*, which actuates the arms *c* and *d*. By means of this arrangement a full "lock" is, it is stated, obtained by the movement of the hand-wheel through a third only of a revolution.

FIG. 3.—SECTIONAL ELEVATION OF RAOUVAL CAR.

The frame *T* (Fig. 4) of the car is built of U-section connected by five stays of similar material; it is supported on the axles by means of plate springs, the body being entirely separate from the frame. Any type of two or four-seated carriage, or a delivery van, may be fitted thereto. The road wheels are of wood, 40 in. diameter rear, and 31½ in. front, and are shod with pneumatic tires. The water-tank is located at the rear, while a cooling coil is carried in front, the circulation being maintained by a small pump. The petrol tank is arranged under the seat of

FIG. 4.—PLAN OF RAOUVAL CAR.

the body. Three brakes are provided: one acting on the hubs of the rear wheels, one on the differential shaft, and shoe brakes on the rear wheel tires. The foot pedal controlling the hub brakes is also so connected that, on its being pressed down, the friction clutch *U* is also put out of engagement; a similar arrangement is provided not only in connection with the pedal which actuates the brake on the differential, but also in regard to the hand lever controlling the tire brakes.

THE PROGRESS OF THE AUTOMOBILE.

BY PROFESSOR R. H. THURSTON.

(Continued from page 350.)

SEVENTY years, two generations, ago a committee of the British Parliament, after a long and painstaking investigation of the working of automobiles in and near London—where there were, a little later, twenty or more at

FIG. 5.—THREE-QUARTER SIDE VIEW OF FRAME OF RAOUVAL CAR. (For description see page 367.)

work, traversing thousands of miles and carrying thousands of passengers annually—after consulting the great mechanical engineers of the day and catechising the inventors, makers and users of the machine, and after cross-examining their opponents among the stage-coach proprietors and drivers, reported that they had become convinced that “the substitution of inanimate for animal power, in draught on common roads, is one of the most important improvements in the means of internal communication ever introduced.” They considered its practicability to have been “fully established,” and predicted that its introduction would “take place more or less rapidly, in proportion as the attention of scientific men shall be drawn, by public encouragement, to further improvement.” The success of the system had, as they stated, been retarded by prejudice, adverse interests, and prohibitory tolls; and the committee remarked: “When we consider that these trials have been made under the most unfavourable circumstances, at great expense, in total uncertainty, without any of those guides which experience has given to other branches of engineering; that those engaged in making them are persons looking solely to their own interests, and not theorists attempting the perfection of ingenious models; when we find them convinced, after long experience, that they are introducing such a mode of conveyance as shall tempt the public, by its superior advantages, from the use of the admirable lines of coaches which have been generally established, it surely cannot be contended that the introduction of steam-carriages on common roads is, as yet, an uncertain experiment, unworthy of legislative attention.”

Gurney had run his carriage between 20 and 30 miles an hour; Hancock could sustain a speed of 10 miles; Ogle had run his coach 32 to 35 miles an hour, and ascended a hill rising 1 in 6 at the speed of 24½ miles. Summers had travelled up a hill having a gradient of 1 in 12, with nineteen passengers, at the rate of speed of 15 miles per hour; he had run 4½ hours at 30 miles an hour. Farey thought that steam-coaches would be found to cost one-third as much as the stage-coaches in use. The

steam-carriages were reported to be safer than those drawn by horses, and far more manageable; and the construction of boilers adopted—the “sectional” boiler, as it is now called—completely insured against injury by explosion, and the dangers and inconveniences arising from the frightening of horses had proved to be largely imaginary. The wear and tear of roads was found to be less than with horses, while with broad wheel-tires the carriages acted beneficially as road-rollers. This parliamentary committee finally concluded:—“(1) That carriages can be propelled by steam on common roads at an average rate of 10 miles per hour; (2) that at this rate they have conveyed upward of fourteen passengers; (3) that their weight, including engine, fuel, water, and attendants, may be under three tons; (4) that they can ascend and descend hills of considerable inclination with facility and safety; (5) that they are perfectly safe for passengers; (6) that they are not (or need not be, if properly constructed) nuisances to the public; (7) that they will become a speedier and cheaper mode of conveyance than carriages drawn by horses; (8) that, as they admit of greater breadth of tire than other carriages, and as the roads are not acted on so injuriously as by the feet of horses in common draught, such carriages will cause less wear of roads than coaches drawn by horses; (9) that rates of toll have been imposed on steam carriages which would prohibit their being used on several lines of road were such charges permitted to remain unaltered.”

The one positive obstruction, legislation for adverse interests, practically killed the automobile before 1840, although here and there an inventor or an enthusiastic automobilist struggled against

all artificial as well as natural impediments.*

The commercial evolution of the lighter automobile systems practically dated from about 1895, though a few makers and users were earlier in the field after the renaissance of the art. In fact, here and there an enthusiastic mechanic and inventor has operated automobiles, usually with steam as the motor, from the time of the decadence of 1833. But the recent remarkable evolution of so many competing systems and classes of motor has

FIG. 6.—BIRD'S-EYE VIEW OF FRAME OF RAOUVAL CAR. (For description see page 367.)

given an interest coming of wider competition that the enterprise formerly lacked and has aided in the stimulation of the development of the automobile most wonderfully. Within two or three years, the business manufacture of all practicable—and of some utterly impracticable—forms of automobile has been undertaken by many capitalists, mechanics, and engineers, and in some cases

* The writer rode in a steam automobile as late, or early, as 1860.

on a very large scale. Electric, steam, and petrol motors seem to have come to stay, each for its special work.

With a hundred, possibly two hundred, manufacturing and exploiting companies in the field, it is obvious that a majority must soon "go to the wall"; but there will undoubtedly, legislation permitting, be a few systems which will conquer all obstacles and a few companies that may secure a market and make a financial success with mechanically practicable forms of vehicle. There will unquestionably result complete failure with the great mass of ill-considered and amateur schemes. There are now in America a very few, not a half-dozen, making the electric automobile, about as many producing the internal-combustion machine, and a somewhat smaller number building the steam automobile. There were, probably, January 1, 1900, less than a thousand automobiles, of all classes, actually operated in America, and not half that number with entire satisfaction. Perhaps two-thirds of these machines are electric, and these are mainly employed in the large cities.

The progress of the automobile has been particularly rapid during the year just closed, especially in England, where the statute which has at last freed all such vehicles generally from the earlier restrictions has been productive of an immense advantage, and in the United States, where native inventive genius has only recently been generally and earnestly attracted toward this great and now most promising field. Should the evolution of the automobile continue unrestricted by unfairly discriminating and hampering legislation, either due to real apprehension of danger, in cities and on the highways, or through the tendency of some legislators toward "strikes" against enterprises involving the extensive use of capital, the progress of the immediate future seems likely to be in the nature of an acceleration, and of astonishing rapidity, extent and importance. The art has passed well through its preliminary stages of experimentation in the cases of the steam-engine as a motor and of the electrically-impelled vehicle, and probably is well advanced in the field of internal combustion motors and of carriage construction. Even progress in the use of the heavier and safer petroleums, both as fuels and as working fluids, is exhibiting some marked advances. Petroleum-spirit motors, however, have thus far led this advance and have a long start in this respect. The French have hitherto been in the van in the operation of the latter class, and England with steam motors; but the indications are that the United States will soon be an acknowledge leader in all lines of improvement of the automobile, as previously with the bicycle. In electric-motor construction the difficulties still remain largely with the accumulator, or storage battery, the size, weight, and cost of which have not been greatly reduced, except at the sacrifice of durability and reliability. Should the storage battery become satisfactory in all respects, we may look for an enormous advance in that line of work.

(To be continued.)

THE 600-mile tour of the three Cleveland automobilists, Messrs. F. L. Strong, W. S. Root, and C. S. Ingalls, through Canada from Buffalo to Detroit, was an entirely successful one, with no breakdown or hitch of any kind. Much of it lay through country where motor-carriages were as yet unknown, and the rural population derived much excitement from the event. Even the village schools suspended session while the unaccustomed machines went by. The longest day's run was from London to Detroit, 105 miles, which were covered in eleven hours, including stops.

MR. FRANCIS E. STANLEY, accompanied by his wife, son, and daughter, made a quick trip from Newton, Mass., to Lewiston, Me., on June 30. Leaving Newton at 4 o'clock in the morning, they reached Portland at 12 o'clock, having made two stops aggregating one hour. The road was rough and heavy, and a very strong head wind was blowing. The actual running time was seven hours, and the cyclometer showed that they had travelled 128 miles. The total distance travelled from Newton to Lewiston, Me., was 161 7-10 miles, and the total running time was nine hours, making the average nearly eighteen miles per hour.

THE GAILLARDET VARIABLE-SPEED GEAR.

WE illustrate herewith a speed-changing gear devised by M. Gaillardet for use upon light motor-carriages. The apparatus comprises a differential gear, a gearing for obtaining two speeds at will, an automatic friction clutch, an automatic brake for controlling the backward and forward running of the vehicle, and a chain-wheel with ratchet. The advantages

FIG. 1.—GENERAL VIEW OF GEAR.

claimed for this system are as follows: (1) It permits of throwing the motor out of gear; (2) the change from a low to a high speed, or inversely, during the running of the vehicle, is effected without any shock; (3) the chain is rendered immovable while the motor is in operation; (4) axles connected with the differential gear through joints assure the transmission of motion without

FIGS. 2 AND 3.—SECTIONAL VIEWS OF GEAR.

resistance even though bearings are out of order or the axles are bent.

The axles are 24 mm. in diameter and 22 mm. at the collar. The entire mechanism is of cemented steel, refined and tempered. It is enclosed in a cast-steel case and operates in a bath of oil.

In addition to the mechanism, the complete apparatus comprises the hubs and the ball-bearings, that is to say, with the exception of the wheels, all the elements of a motor hind-carriage for a motor-cycle or a voiturette.

THE new prices of the United Motor Industries will come into force on the 1st prox., when the firm's new price list will be ready.

MOTOR-CAR ACCIDENT NEAR COVENTRY.

MR. J. W. MAUDE, of Coventry, met with a startling accident last week whilst driving his motor-car along the Kenilworth Road. In the car with him was his wife and mother, whom he had been taking for a drive through Berkswell, and was returning home. On reaching Gibbet Hill, and while the car was running at about ten miles an hour, the axle of the vehicle snapped. Mr. Maude, with cool presence of mind steered the car on to the grass at the side of the road, where the vehicle overturned, and the occupants were thrown out. Though severely shaken, they marvellously escaped serious injury. Mrs. Maude, sen., who is over seventy years of age, suffered most from the shock; it was feared that she had sustained injuries to her ribs and collarbone, but it was found that her injuries were confined to bruising and shock. Mrs. Maude, jun., was considerably shaken and bruised, and also sustained some laceration of her face. Mr. Maude escaped with a shaking. The vehicle was badly damaged. The cause of the axle breaking is attributed to a fracture caused by a collision some time ago, and which careful examination had failed to reveal, although after it had snapped, it was evident that it had been holding together by a small portion only. The two ladies were kindly conveyed home by Mr. Hugh Rotherham in a wagonette, and are making satisfactory progress.

FURIOUS DRIVING CASES.

AT the Worthing Petty Sessions last week Mr. Allan Hickman was summoned for furiously driving a motor-car in Brighton Road, on the 6th July.—Mr. Staplee Firth appeared for the defence.—P.C. Prior deposed that he was on duty near the Half Brick, on the day in question, when he saw the defendant in company with another man driving a motor-car along the Brighton Road at a speed of twenty-five miles an hour. Witness called his attention to the rate at which he was going, and he replied that he could go as fast as he liked when there was nobody else in the road. Witness timed him over a certain part of the road—from Onslow House to the Half Brick—and on measuring the distance the same evening he found the distance covered in the minute was 860 yards.—Cross-examined by Mr. Firth witness said his watch was not a stop watch, but it had a second hand. He did not understand the mechanism of a motor-car, and could not say whether or not it was possible to drive it at a speed of twenty-five miles an hour. He did not behave rudely to the defendant. He saw no one on the road who was in danger from the motor-car, but a lady cyclist was riding along the road in the opposite direction.—Frederick Strudwick, a gardener, living in Brighton Road, said he was in his garden on the day in question, and saw the motor-car go past. When he first saw it, the motor was passing Onslow House, and he watched it till it got out of sight. Witness thought the motor-car was travelling twice as fast as those which went along the Brighton Road daily, or say at twenty miles an hour.—Addressing the Bench for the defence, Mr. Firth pointed out that his client had been summoned for driving at a greater speed than was reasonable and to the common danger of the public, and he submitted that no evidence had been adduced of anyone having been in danger in this instance. The Chairman, after consulting his colleagues, said the Bench accepted Mr. Firth's definition of the law, and the summons would be dismissed. Mr. Firth said he had brought two witnesses from Sutton, Surrey, and one from Northampton; he asked the Bench to allow something towards their expenses. The Bench agreed to allow railway fares, 10s. each for the witnesses from Sutton, and £1 1s. 6d. for the witness from Northampton. Superintendent Bridger handed a statement to the Bench, and protested against any expenses being allowed.—The Chairman, to the defendant: We did not know before that there were two previous convictions against you. You ought to be very careful. Mr. Firth protested that the Superintendent had no right to bring any record against his client, unless the Bench had found him guilty of the present charge.

THE Buxton magistrates on Saturday last fined George Smith, cycle agent, Buxton, 40s. and costs for furiously driving a motor-tricycle in Spring Gardens on July 8th. Two constables swore that defendant was going at the rate of fifteen miles an hour. Defendant contended that the machine was incapable of such a rate.

AT Oxted Petty Sessions on Monday, Mr. William H. M. Burgess, of Norwood, was summoned for furiously driving his motor-car at Godstone on July 7th, on which day the club held a hill-climbing contest at Tilburstow Hill. The police stated that the defendant drove into Godstone at a speed of from seventeen to twenty miles an hour. Mr. Burgess, however, said his pace did not exceed fourteen miles, and the case was dismissed.

A. E. PRICE, Foleshill Road, Coventry, a driver in the employ of the Daimler Motor Company, was summoned at Northampton on Saturday for furiously driving a motor-car.—William Goode, a tram-driver, employed by the Northampton Streets Tramways Company, said on June 26 he was driving through Northampton when he saw a motor-car approaching on the wrong side of the road. The motor crossed the road, ran into the tram, and injured the horse's leg. The front of the tram was damaged, and he was knocked through the door, his ribs and shoulders being cut and bruised.—Defendant said the motor was not travelling more than seven or eight miles an hour. The car skidded on the tram lines, or he would have been able to pass.—One witness estimated that the car was travelling between twenty and twenty-five miles an hour.—A fine of £5 and 13s. costs was imposed.

MOTOR-CAR FATALITY.

MUCH excitement was caused at Kenilworth on Monday by a motor-car accident which, unhappily, terminated fatally. It appears that Mr. Harris Ely, of Ulverstone, the consulting engineer to the North Lonsdale Cycle Company and district inspector for the National Telephone Company, had purchased a motor-car from Messrs. Allard and Co. on the previous Saturday. He started on Monday for his first tour, intending to go to Bristol. He got along at a fair speed until at Kenilworth his car suddenly stopped dead for an instant, rose upon its front wheels, and overturned forwards, dashing the unfortunate gentleman with great force to the ground. His companion immediately rushed to Mr. Ely's assistance, as did several people who were in the vicinity, and heard the hissing noise of the overturned car; but they found that he was lying dead, with the fore part of his head crushed in. When the police righted the car to take that along as well, they found, it is stated, that a pin was missing from the steering gear actuating one of the front wheels of the car, which had, apparently, turned broadside on, and stopped the car dead, with the result, of course, that it instantly capsize. The missing pin, it is further stated, was found lying in the road near a cottage a little way further up the hill.

At the inquest held on Tuesday Mr. James Montgomery, Messrs. Allard and Co.'s works manager, said he was riding on a motor-cycle in company with the deceased on the car, on the morning of the accident. He had since examined the car, and believed the deceased had put the low speed belt on the motor in descending the hill, which would have a checking effect upon the car. There was also a pin missing from a joint on the rod which connected the two steering wheels. Either of those matters would cause the accident, and witness could not say which. The witness explained to the jury that the low-speed belt, if put on, would act as a brake on the car and check it to about five miles an hour, no matter how steep the hill was. He said he was convinced that this was the cause of the accident until he saw the pin. He was of opinion that the deceased had been running down the hill with both belts off, and at the time of the accident had put the slow belt on. He thought it was probable that the pin which came out had had several severe wrenches on Sunday, when the deceased was trying the car, and swerved the steering of it several times violently, and once ran into the bank in trying to turn it round. The deceased had overhauled the car on the morning when he started, and witness considered it possible that he had loosened the pin in doing so. It was possible that it might work loose, like all nuts and bolts. Mr. Valentine, Leamington, consulting engineer, who said he had owned and driven motor-cars, gave it as his opinion that the loss of the pin and the freeing of the wheel caused the same to turn outwards and lock, with the result that the steering bar went among the spokes and the car overturned, the whole weight of the machinery being in front. The jury found that death was due to a fracture of the skull, produced by the overturning of the car, which the loss of the pin from the steering gear caused.

AN ASSAULT CASE.

THE Hon. Lancelot Lowther, of 33, Lowndes Square, W., appeared at the Westminster Police Court on the 25th inst., in answer to a summons charging him with assaulting M. Ferdinand Bouquet, a Frenchman, employed as a motor-car driver.—Mr. J. D. Langton said on the afternoon of the 17th inst. the complainant was driving a motor-car from Hyde Park, and encountered considerable traffic on crossing into Grosvenor Place. He slowed down in consequence, but having cleared it, increased his pace to eight miles an hour. The defendant, who was in a hansom cab, was also crossing Grosvenor Place, and the two drivers, each under the impression that the other would cross his front, pulled up. Then the motor-car went on, the complainant taking it to the stable in Royal-oak Place, Eaton Square, about three-quarters of a mile from Hyde Park Corner. The complainant was attending to the machinery, when suddenly, to his astonishment, he found the defendant by his side, having followed him in the cab. The defendant used some very offensive expressions, lifted his stick, and struck him across the face with it.—The complainant, in bearing out Mr. Langton's statement, said he drove a motor-car for Mr. Mulholland, of Sloane Street.—Cross-examined by Mr. Danby, who appeared for the defence, complainant said he had had five years' experience in London and Paris as a motor-car driver.—Mr. Danby said his case was that the motor-car was driven at the rate of fifteen or sixteen miles an hour, and the defendant's cabman had to pull up sharply to avoid a collision. The defendant being annoyed, instructed the cabman to follow the car, and admitted that he did "tap" the man with his stick in anger. The defendant, who elected to be sworn, said he was irritated when his cabman had to pull his horse back on its hocks. The motor-car went by like a flash of lightning. He shouted to the driver to stop, but he only turned and kissed his hand to him. He thought it disgraceful that a man should be allowed to behave so, and followed the car to some mews. He remonstrated with the driver, but he only giggled and gesticulated, and at length he said, "If you go on laughing at me like that any longer I'll give you a good hiding." The man giggled and grinned again, and raising his stick struck him. He afterwards saw the defendant's master and apologised, but the defendant asked for £20 compensation, saying that he would then hold his tongue about it, and the affair would not get in the papers. He refused to do anything of the sort.—Mr. Horace Smith suggested that something in this way might be done now, and after a brief consultation Mr. Langton consented to withdraw the summons on payment of the costs and reasonable compensation. It was understood that the motor-car driver received a £5 note.

THE Motor-Car Journal.

VOL. II.]

LONDON, SATURDAY, AUGUST 4, 1900.

[No. 74.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

TOURS in Ireland are becoming very popular this year, and the success of the several private trips that have been made should do something to bring nearer the tour which the Automobile Club may make, some day, in the Emerald Isle. Several members of the Irish aristocracy are enthusiastic motorists, and we now learn that Lord and Lady Iveagh have started for a tour round

Ireland in their Panhard motor-car. They intend to be away two or three weeks, visiting for the night those friends whose houses are on their route, Lord Waterford's beautiful place, Curraghmore, being one. Mr. Ernest Guinness, Lord Iveagh's second son, and Mr. Ward are making the same tour in a smaller vehicle, and luggage and servants follow by train. In some of the remote districts of Ireland motor-vehicles are very unfamiliar things, so that these trips are really educational as well as pleasant.

A Generous Motorist.

ONE of Lord Iveagh's sons driving a Mors car in Ireland last week, had the unpleasant experience of being involved in a rather serious accident, through a horse yoked to a hackney car taking fright at the motor. The animal made such a kick-up that two of the passengers were flung heavily to the ground, one of them being severely injured; whilst the car was completely wrecked. Though in no way to blame for the mishap, the motorist behaved in a manner befitting the munificence of the Guinness family, as he had the victims promptly attended to and since then richly compensated. The jarvey also has been presented with a new car, and in all probability is a material gainer by the occurrence.

Railways Spoil Automobilists' Plans.

MR. ALFRED HARMSWORTH had the intention of touring in the West of Ireland recently on his Panhard car, but he found that owing to the refusal of the Irish railway companies to carry petrol this would be almost impossible. Consequently he relinquished the idea and visited Connemara in the manner of the ordinary tourist. He was much impressed by the suitability of that district as a motor-touring venue. The roads are of good surface and mostly level, whilst the scenery is only second to Kerry in its grandeur and variety. Excellent hotels also are numerous. The only drawbacks are the climate and the petrol difficulty. We trust that the latter will be speedily removed; and then the weather clerk may be shamed into giving a better climate.

Stag Hunting and Automobilism.

THE usefulness of motor-vehicles to hunting parties has long been recognised in France and occasionally proved in this country. Now that the stag hunting season has commenced large parties of enthusiastic sportsmen are making their way to the moors, and doubtless the automobile will be to the front in the transport arrangements. We learn that a party of motorists is being made up to journey to Dulverton in September, and at the end of that month a notable company will be assembled at a popular inn at that place, including Sir Walter Besant, Mr. Rudyard Kipling, and Mr. Conan Doyle.

Gymkhanas.

THE recent automobile gymkhanas at Ranelagh and Sheen House have occasioned much discussion, and considerable diversity of opinion has arisen as to whether they are calculated to increase the popularity of the motor-car among the class of people likely to become purchasers. Unfortunately, the public does not realise that the panting and throbbing often associated with a car at rest is lessened considerably when running, and to bring crowds of people to see motor-vehicles waiting to start on short contests is an advantage of dubious value. On the other hand, it is claimed that such displays afford opportunities for demonstrating the perfect control which can be obtained over the car, and so giving confidence to those who are sympathetically inclined.

At Sheen House.

THE ground at Sheen House was much smaller than that which the Automobile Club obtained at Ranelagh, and although the circular nature of the course was rather against the higher powered cars, the spectators were better able to see the whole of the proceedings than was the case at the earlier gymkhana. There were six events last Saturday, and although the attendance was not large, the various contests were greatly enjoyed. At the conclusion of the programme the prizes were distributed by Mrs. Arthur Firth.

The Contests.

THE first event was a bending race for motor-carriages in which, after going to the outward destination, the vehicle had to return backwards. This was won by two lengths by the Hon. C. S. Rolls from scratch on his 12 h.p. Panhard, Mr. J. W. Amps, who was allowed fifteen seconds start, being second on a 4 h.p. Daimler. In the contest in which the motor-carriages had to be started from cold, Captain Langrishe (five seconds start) got home first on his 6 h.p. Peugeot, being about twenty yards ahead of the Hon. C. S. Rolls (scratch), who was second. Perhaps the most amusing event of the afternoon was the motor-tricycle coat and waistcoat race. At the end of the first lap the competitors had to stop, dismount,

take up their coats, and hang them on numbered pegs; at the end of the second lap they had to take off waistcoats and hang them on the same peg; at the end of the third lap they had to put on coats and waistcoats, and having fully buttoned both, finish at the end of the fourth lap. In this Mr. Rolls, who had 7sec. start, was first, Mr. C. Jarrott, starting from scratch, finishing second. Mr. Jarrott, however, turned the tables in the obstacle race, finishing first with 41sec. start, Mr. Rolls (scratch) being second. The starting and stopping handicap concluded the contests. Of the seven starters none knocked the "brick wall" over. Mr. Jarrott (5sec.) was in first, Mr. R. E. Phillips (3sec.) being second, only an inch or two in front of Mr. Rolls (scratch).

More Competitors Wanted.

ONE unfortunate point in connection with these contests—both so far as gymkhanas and motor-racing are concerned—is the fact that no new competitors seem inclined to participate. Occasionally we have a new man, but as a rule the events are all taken part in by the same people. Of course they are proficient and their performances are good, but the success of such gatherings in the future will largely depend on whether new competitors are found. Otherwise the novelty is likely soon to wear off.

The Liverpool Association Run.

THREATENING weather at the start prevented anything like a good representation of the Liverpool Self-Propelled Traffic Association taking part in Saturday's run. The programme was to leave Seacombe ferry shortly before one o'clock and proceed to Leasowe Castle Hotel for luncheon. Thence *via* Hoylake, West Kirby, Caldy, Thurstaston, Heswall and Eastham, to Hooton Park Club, for tea, after which the members were to disperse at their convenience, but not before 6 o'clock. The inclemency of the weather in the forenoon caused the withdrawal of no less than eight cars, and only Mr. W. Winwood Gossage and Mr. E. Shrapnell-Smith, on Perfecta quadricycles, went round. Mr. and Mrs. J. Walwyn White crossed to Seacombe, but their car had been detained in Manchester. The weather turned out fine and bright, and a most enjoyable run was the reward of the few who decided to risk the threatening aspects. The roads were good. Mr. Shrapnell-Smith had a spill in the Leasowe Castle Grounds. Riding his machine round a sharp corner he was pitched off, executing a somersault in consequence. Fortunately he escaped with nothing more serious than a hurt ankle, which will keep his foot from the ground for a while.

A Motor-Car In Camp.

THE Forth Volunteer Infantry Brigade, which has been accompanied by Lord Kingsburgh, has been in camp at Lochcote, Linlithgowshire, and a motor-car has been employed to carry the mails from the camp and the railway station. It has considerably facilitated matters and demonstrated another aspect of its value. Certainly in this matter Scotchmen seem more enterprising than the people south of the Tweed, and the Volunteer leaders are showing greater intelligence than the War Office.

An Early Steam Car.

THE credit of having produced in the early part of the century a steam coach, excelling in commodiousness and luxuriousness the horse-drawn stage coaches and travelling carriages of the time, is due, it would appear, to a Mr. W. H. James, who, in conjunction with Sir James Anderson, Bart., constructed and ran about 1829 the road coach illustrated on page 378. This commodious coach was driven by two separate engines, each comprising a pair of horizontal cylinders, one engine being allotted to the near side driving wheel, and the other to the off side, the axle being made in two distinct portions. Indeed, it was a twin-carriage both in regard to engine and boiler,

the advantages of which were demonstrated on one occasion when, in running through Epping Forest, one of the boiler tubes—which were nothing more nor less than ordinary gas pipes—split, and put out one of the fires; with the remaining boiler and engine the carriage returned home at the rate of about seven miles an hour, carrying a load of more than twenty passengers. It was a very heavy and substantially built vehicle, weighing, with its complement of passengers, something like seven tons.

Motor-Car Auctions.

As previously recorded in our columns Mr. Ernest Owers occupies an unique position as being the only auctioneer who is interesting himself in motor-vehicles—not only from the practical but also from the selling point of view. At his auction sale last Saturday three cars—a Daimler, a Benz, and a Decauville—were sold, and also a motor-tricycle. Owing to the holiday season there will be no auction sale in August. The next public sale by auction will take place on September 28th.

The English Motor Club.

ON Saturday, the 11th inst., the English Motor Club will organise a run to the White Swan Hotel, Cobham, Surrey, where tea will be served at 4.30 p.m. The run will be extended to the Pond House, Frensham, *via* Guildford, Godalming, and Chart; dinner will be taken at Frensham at 7.30 p.m. The return to town will not be till after lunch on the following day. Motorists generally are invited to take part in the run.

The Roads Round Cardiff.

So bad are the roads in some parts of Wales that the local authorities have refused to license motor-cars to run thereon. That is the most charitable view we can take of the action of the Cardiff Corporation. At the last meeting of the Cabs Committee of that body the clerk read an application from the Cardiff, Whitechurch, and District Motor-car Company for leave to run motor-cars between Cardiff and Whitechurch. Mr. Chappell was of opinion that it should not be granted, and Mr. Hallett remarked that the road did not seem to be in a fit state for such traffic. Besides, the road was dangerous, especially at the Maindy Dip, and it was a wonder to him that there had not been many vehicle accidents on that road. No doubt a good service was wanted on that road, and if the road were put in proper order he would support the application made by the company. Ultimately it was decided not to grant the permission asked. Will the Corporation improve the roads?

Improving the Roads.

SEEING that the local authority has, in this case, practically acknowledged the unsafe character of the roads, the practical men on the council should recognise their duty without delay; for the development of the roads round about that pleasant town would not only be a source of delight to the residents but also a means of profit to the hotel keepers and others. Wales has been long neglected by the great body of automobilists and it only needs an improvement of some of the roads to attract them thither.

The Side of the Road.

ONE can understand unpaid magistrates who have had no legal training failing to appreciate legal distinctions, but it is surprising to hear of a magistrate of Mr. Francis' reputation giving it as his dictum that the fact of a vehicle going on the wrong side of a refuge is (*per se*) evidence that the public are in danger. In fact, if this dictum has anything in it, every automobilist will be convicted, not for what he has done, but for something which he might do. Such a misconceived notion of the law it is difficult to appreciate, especially as the learned magistrate had quoted to him by the advocate for the

defence several cases which were decided in the High Court, in which it was held that where qualifying words are introduced there must be affirmative proof of the condition to support the circumstances set out in the qualifying words.

A Practical Point.

In one of the Norwich papers a correspondence has been going on with regard to motor-car speed which has elicited a reply from Mr. Ernest Estcourt, in the course of which he says:—"My experience, after driving cars 30,000 miles without injuring man, woman, child, or dog, is that the best thing to do in passing vehicles going in the same direction is to get by at a good pace. The horses take less notice, and when once passed the quicker the car is in leaving the horses the better for all. In meeting a horse it is better to come near at a good speed, as by so doing the engine can be thrown out of gear, and the car run past on its own momentum, thus saving the noise of the engine and gear. Experienced motor-car drivers have found this is best, and in a few years the drivers of horses will think so too, and not trouble so much about the speed as the care of the driver

Safety in Lincoln.

THE progress of the motor-car in Lincoln has aroused the ire of a resident who rather deplores its extended popularity in the city. We are glad to see, however, that he is practically alone, and that the editor of a local contemporary declares that anyone "may cross the streets without the slightest fear of being knocked down." There is no doubt that the fears of nervous folk with regard to automobiles are mainly the result of a too vivid imagination which sees trouble in common matters and danger in everything.

A Trip on an Electric Car.

ELSEWHERE we record a run to Brighton on an electric car, the carriage work of which was by Mr. Mulliner, of Northampton, and the electrical and mechanical part by Messrs. Joel and Potter, of London. During the run only one charge of electricity was used, and the total run on the day was fifty-three miles by cyclometer. We give the particulars of power, etc., as being of interest to all interested in the development of electrical cars, and the further performances of this voiturette will be regarded with considerable interest.

Cliche de

VISIT OF THREE GOVERNORS FROM ANNAM TO THE MORS WORKS.

[La France Automobile.

in other respects, such as preventing noise, giving plenty of room, not attempting to pass until there is room, not blowing the horn near horses, etc. My experience also teaches me that in nine cases out of ten the drivers of horses are much more frightened than the horses are. In proof of this I would say that my London stables are situated in a mews where there are about 200 horses, and although I have kept my cars in the centre of this mews and opposite a stable that usually contains 120 horses, I have never once been asked to stop for a restive horse. The men expect me to drive in and out just the same as though I was driving a horse."

Motor-Cars at Sandown.

MOTOR-CARS are becoming familiar at all race meetings, and the fact that the Prince of Wales went down to Sandown on a motor-car should do something to render them even more popular in such circumstances. In the members' enclosure, Mr. Hwfa Williams received His Royal Highness, and while they were standing, before moving on to the Royal stand, the starters for the Cobham Plate came filing down from the paddock, some of them looking at the motor-car with curious eyes, but none showing any alarm. There is a great difference between blood horses and half-breds in the matter of courage and intelligence—and this applies to all phases of equine experience. Anyone shipping horses, for example, will find it as easy again to ship a thoroughbred as a half-bred.

Celestials Inspect the Motor-Cars.

IN connection with the Exhibition, three great mandarins, governors of the three states of Annam—Vu-Quang-Nha, Tran-Dinh-Luong, and Hoang-Trong-Phee, have with their suite lately been doing the sights of Paris. Included in the programme was a visit to the works of the Mors Company at Grenelle, where the visitors displayed great interest in the construction of automobiles. But their delight was the greatest when an opportunity was afforded them of making a short trip on one of the cars. Our first illustration shows the party just arrived at the Mors works, while the second one shows the three governors making their *début* in an automobile.

Looking to the Future.

THIS suggests the many markets that will be open to motor-car manufacturers in the future—when the countries of the East are more settled in their governments and manners. In some of those remote countries the motor-vehicle will be very serviceable in connection with transport arrangements, and as commercial men open up new sources of trade they will do well to bear the advantages of automobilism in mind. Certainly the interest of Chinamen, Japanese, and others in motor-cars is very apparent whenever they are able to enjoy trips on automobiles in Europe. The time is coming when the export trade as well as the home market will have to be considered.

MOTOR-CAR TRIPS.

FROM BOURNEMOUTH TO LONDON.

MOTORISTS are pleasantly familiar with the delights of automobile excursions, and will hear with pleasure that the members of some of our local authorities are also becoming appreciative of such excursions. Some of the members of the Pokesdown Urban District Council have recently had a two days' motor-car excursion to London and back, and the outing was thoroughly enjoyed. No hitch occurred to mar the gaiety and the novelty of the proceedings, while from an economical point of view the excursionists should be well pleased. Mr. F. Elcock, the chairman of the Council, seems to have been the leading spirit of the enterprise, and having made arrangements with Mr. F. J. Bell for the hire of one of his cars for a couple of days, made up a party of the following gentlemen:—Messrs. J. Carter, R. Parsons, G. Fall, and F. Elcock, members of the Pokesdown Urban District Council, and Messrs. J. Edwards, G. Carter, F. Scott, and S. Whittaker; W. McArdle was the driver. They started from Pokesdown, Bournemouth, at six a.m., and passed through the following towns and villages to Putney, which was reached at seven p.m., viz.:—Christchurch, Lyndhurst, Totton, Redbridge, Millbrook, Southampton, Chandler's Ford, Winchester, King's Worthy, East Stratton, Popham, Basingstoke, Nately Scures, Hook, Hartley Row, Hartford Bridge, Blackwater, York Town, Camberley, Bagshot, Sunningdale, Egham, Staines, East Bedfont, Feltham, Twickenham, Richmond, Mortlake, and Putney. Breakfast was partaken of at the Black Swan, Winchester, and luncheon at the White Hart, Hook.

After visiting their friends in London the company started at 8.30 on Tuesday morning, and returned home via Putney Heath, Kingston Vale, Kingston, Surbiton, Esher, Cobham, Ripley, Guildford, the Hog's Back, Farnham, Alton, New Alresford, Itchen Abbas, Winchester, Standon, Hursley, Anfield, Romsey, Owen, near Rufus Stone, Crow, Kingstone, Avon, Sopley, and Christchurch, arriving at Pokesdown at 10 p.m. In the down journey stoppages were made at the Crown, Alton, for lunch, and tea was partaken of at Romsey. This very interesting trip, through some of the loveliest parts of Hampshire and Surrey, took place without accident of any kind, and the divided cost, embracing hire of car two days, two luncheons, one breakfast, and one tea, with fee to driver, amounted to £1 11s. 8½d. each person, which certainly was very moderate considering the amount of pleasure that was experienced all round. So successful was this first venture that it is Mr. Elcock's intention to get up one or two other like excursions to other places before the close of the season.

FROM LONDON TO BRIGHTON.

On Saturday last a pleasant trip was enjoyed on a two-seated voiturette propelled by electricity, and constructed under the patents owned by the National Motor-Carriage Syndicate, Limited. The two trippers started from Wilson Street, Finsbury Square, at 11.30 a.m., and passed through the congested traffic over London Bridge by the Borough, Kennington, Brixton, Streatham, Croydon, Merstham, Redhill, Horley, Crawley, Handcross, Hickstead, and Patcham to Brighton. The voiturette is equipped with two 2 h.p. Joel electric motors, running at a speed of 600 revolutions per minute with thirty volts. These two motors are fixed on a detachable spring frame, and drive the two back wheels of the carriage separately by lin. chain gear of 9 to 1. The current is supplied by thirty-two Rosenthal storage batteries, made up in two sets of sixteen cells, joined in parallel, giving thirty-two volts and 20 to 40 amperes, with an output of 140 ampere-hours. The total weight of the carriage is under 12cwt.; of this 7½cwt. is battery, motors 2cwt., and the carriage itself only 2½cwt. The wheels have pneumatic tires, the back wheels are 2ft. 9in. diameter, and the front wheels 2ft. 6in. diameter. The front track is 3ft. and back track 4ft. 6in., and the base is 4ft. 6in. The controller is very simple in construction and action. The system of electrical changes is such that when the voiturette is ascending hills the motors work at

their highest efficiency and at normal speed; they are geared down to run the car up hill at six miles an hour, whilst on the level the car is run from eight to twelve miles, or faster if desired. There are also two slow speeds forward of three and four and a-half miles, and a slow speed backward of three miles per hour. When going down hill the motors act as a brake, and on steep hills give a back charge to the batteries. A careful series of tests were made on the journey, and the current used was measured. On level roads, such as from the Elephant to Croydon, the current varied from 10 to 20 amperes per cell; on inclines of 1 in 40, such as experienced between Croydon and Merstham, the current rose to 40 amperes per cell, the average current used being about 20 amperes per cell. On the steepest part of Redhill the current touched 45 amperes per cell, this with a pressure of 32 volts giving an effective of 4 h.p. to the carriage. On the other hand, when going down Merstham hill, Earlswood Common, Handcross hill, etc., the battery was recharging about 15 amperes per cell, or practically returning about one-fourth of the current, the returned current making an appreciable difference in the run. Of course, on level roads the distance travelled would have been very much greater. The run was made at an average speed of ten miles per hour, or in five and a quarter hours' actual travelling, and varied from fifteen miles per hour on the level or slight inclines to six miles per hour going up the hills. The roads were in good condition, but a very strong head wind prevailed throughout.

FROM MANCHESTER TO LONDON.

I fancy, writes Mr. J. Reginald Egerton from Sheen House Club, that your readers have heard very little about the "Century" tandem motor-tricycle, except its splendid performances during the 1,000-mile Trial, therefore I venture to send you a short description of it, as I feel sure it meets a long felt want—namely, a reliable machine, which is at the same time a good hill climber, free from noise and smell, and easy to drive and manipulate, and last, but by no means least, comfortable. I speak from personal experience, having driven many of these machines, two of them from Manchester to London, one fitted with a 3½ h.p. water-cooled engine, and the other with a 2½ h.p. air-cooled engine.

On the first-named machine, which was, of course, much the fastest, we ran, in the early hours of the morning, several miles just under 1½ min. per mile, and we actually cleared 37 miles in one hour, but our average was completely spoilt by having to run very slowly during the dark hours. Never having been over the road before we had to stop at almost every sign post to try and find out the way. On more than one occasion we had to retrace our steps. I had a mackintosh on over my other clothes, and my passenger wore a sweater as well as a mackintosh, and so we managed to keep fairly warm. One stop we had, besides the necessary one for oiling up, feeding and lubricating ourselves, and for finding the way, and that was to find out why the water-cooled engine was not being cooled with water, though the pump was revolving quite as it should do. This, however, was not a very difficult thing to discover, and when put right we had no more bother with the water circulation, the engine always keeping beautifully cool at the highest speeds.

We left Altrincham, just outside Manchester, at five o'clock in the evening, and travelling via Knutsford, Holmes Chapel, Newcastle, Stone, Rugeley, Lichfield, Coleshill, Stonebridge, Coventry, Dunchurch, Daventry, Towcester, Stony Stratford, Fenny Stratford, Dunstable, St. Albans, and Watford, reached Uxbridge (180 miles) at nine o'clock next morning, having had a most enjoyable ride—I speak for my passenger as well as myself—over, in most places, absolutely perfect roads. One piece of road, though, was anything but good, being practically disused, and ending in a sort of dried water-course, up which, to save the tires, we pushed the machine. It was between Rugeley and Coleshill, and, curiously enough, when going over the same course with the air-cooled Century two weeks after, and though taking special care to watch all the sign posts, and so on, yet we were once more confronted by the self same pre-historic road, and also, curiously enough, I have not as yet been able to make out where I went wrong, and by what road I should have travelled. As I shall

probably have occasion to travel from Manchester to London on several future occasions, I should be much obliged, if any of your readers who know the district which baffled me could give me help on the subject.

The run down on the 2½-h.p. air-cooled Century was, take it all round, a better performance than the previous one. Of course we had no pump troubles, being air-cooled, and we had much less frequently to retrace our steps; and again, there being a full moon, one could run faster during the night, and one also knew more when the nasty turns and corners were coming, so that, although our machine was ever so much slower than the water-cooled one, we got to Kilburn and Brondesbury station at 1.29 noon, only leaving Altrincham at 9.40 the previous evening, and stopping at Stony Stratford a long time, quietly looking over the machine, and tightening any nuts that might be loose (as the machine was brand new, and had had no chance for things to shake down into their proper places before) the usual motor-man's wash and breakfast, and a quiet lounge in the smoking-room.

Besides this prolonged stop, we got down about every 25 miles to oil up, and once pushed the machine up a hill to warm ourselves, as we were both actually chattering with the cold, and my passenger, who by the way is the owner of the machine, was wrapped up in a thick mackintosh. I am told that on the night in question, July 14th, people could not get to sleep for the heat, and they look at me with a "bit-of-a-liar-myself" sort of look when I tell them I was unbearably cold for about three hours that night. Motorists will, however, credit my statement I know.

Now, as to the machine, the frame, which is made of large steel tubing, is the same for either engine—the choice of the engine being absolutely left to the buyer—and is so constructed that the front wheels when going round a curve lean over towards the inside of the curve. The front seat, which is upholstered in leather and hides two large supply tanks, is suspended on C springs, making it very comfortable. The footboard is so constructed that it can be heated in the winter by the hot exhaust. The machine is chain driven, first on to a counter-shaft, on which are two friction clutches, and thence to the back or driving wheel. The chains are of the automatic pitch type, and are very strong indeed, and cannot come off. The vehicle has two speeds and a free wheel, and two brakes, namely, a tire brake and a band brake on the hub of the back wheel, both of which are operated with the foot. The steering is controlled by a side lever, and it is difficult to believe how simple it is. The ignition, which is electric (dry battery and coil), is timed by a little lever on the steering handle, which is very easy of manipulation, and by the use of the electric switch, convenient to the driver's hand, the current may be switched off at any time. The carburettor is a modification of the surface type, and is under the footboard of the driver's seat, the float being under the driver's eye, as is the whole engine.

OUR Midland representative writes:—I called at the Star Motor Works in Wolverhampton a few days ago and was shown by Mr. Prew his new carburettor at work in one of the Star cars. The great advantages claimed for it are that it will work with either light or heavy oil, is much more economical in its consumption of oil, and is, as a matter of course, most suitable for tropical countries. I was afterwards shown one apart from the motor and was struck with the simplicity of it; there is nothing about it that can get out of order, and every part of it is easily accessible.

A NEW price list is being issued by the United Motor Industries, Limited, which is a considerable improvement on the old one. It now has an index, obsolete lines have been removed, and many new lines have been introduced, and in this particular the catalogue will be of especial interest to those firms who propose building cars in this country. The prices have been rearranged and in some cases reduced, and in a few cases where there has been no option in the matter they have been increased. The catalogue comprises 130 pages, and is issued at one shilling. The illustrations are a special feature worthy of notice.

SOME NEW MOTOR-BICYCLES.

IN our report of the recent Automobile Exhibition at Brussels we referred to the motor-bicycle shown by La Société des Usines Delin, of 7, Marché au Poisson, Louvain. We are now able to publish in Fig. 1 an illustration of the machine, together with a few additional particulars. As will be seen, the frame is of special construction, to enable the motor to be carried within it just in front of the bottom bracket. The motor is of the single air-cooled cylinder type, it is of 1½ h.p.

FIG. 1.—THE DELIN MOTOR-BICYCLE.

capacity, and has electrical ignition and Longuemare carburettor. No pedals or chain are provided, the motor driving the rear wheel hub through a long shaft and bevel gearing, very much on the lines of the chainless bicycle. Two brakes are provided, a tyre brake on the front wheel and a band brake on the rear wheel hub. The machine, which weighs complete 176lb., has been tried on some of the worst roads, and it is stated to have attained an average speed of 60 kilometres per hour. The position of the motor is stated to render the machine exceedingly stable.

FIG. 2.—THE "CENTAURE" MOTOR-BICYCLE.

Fig. 2 shows the "Centaure" motor-bicycle recently introduced by a Paris firm. The motor, as will be seen, is supported behind the saddle over the rear-wheel; it develops just over 1 h.p., and weighs 22lb.; it is air-cooled and provided with electric ignition. The transmission is effected by a strap working on a pulley attached to the rear wheel. The small pulley is not fixed on the crank shaft, but on a short shaft driven by spur wheels off the crank shaft at half the speed of the latter. The petrol tank has a capacity sufficient for a run of 100 kilometres. The weight of the machine complete is given as 74lb.

CORRESPONDENCE.

A NEW CAR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Herewith I send you a photograph of an experimental car, designed by Mr. F. L. Martineau and myself, which may be of interest. We are very pleased with the results obtained, as, although we have only $3\frac{1}{2}$ h.p. and the car weighs 10 cwt., we can average seventeen miles per hour over hilly country, the top speed being over twenty miles. This is due to the very efficient chain transmission. We have quite got over

the pump trouble by the simple expedient of not using one, and find we can run over one hundred miles on a hot day without renewing our water supply, which is under three gallons. The car is very silent and smooth in running, and quite comes up to our expectations.

Yours truly,
155, Buckingham Palace Road, T. B. BROWNE.
London, S.W., July 30th, 1900.

THE 1,000-MILE TRIAL.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In reply to Mr. Jones, I take in *The Motor-Car Journal*, and have spent some pounds in looking for a "silent, simple, and reliable car." I certainly do not find it in the vehicle named, which, like the rest of oil-driven motors is noisy, uncertain, and complicated, and in the trial did not face the Shap Fell Hill, which the "Locomobile" steam-car did with its two passengers. My experience and trial is very much in favour of the "Locomobile." It is silent, certain and easy to handle.

My object in writing was not to advertise any particular car, but to obtain some data as to working, cost, and repairs, which in the Trial was not taken into account, but to an ordinary buyer is an all important matter, and to me seems a serious item with oil cars.

A PURCHASER.

Reading, July 30th, 1900

PNEUMATIC TIRES AND PUNCTURES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Can any of your readers inform me why a layer of thick leather belting should not be fixed between the inner tube and outer casing of pneumatic tires. The leather belting might be chamfered off at the sides to allow for curvature of tire. If successful, this ought to render a puncture impossible and would also, no doubt, tend to lessen the bounce which a heavy, fast car shod with pneumatics will give on bumpy roads. When I ordered my Mors car twelve months ago I was talked into having pneumatics, but found the car bounced like a rubber ball over bad roads. So when I had a puncture I had solids put on, but finding that steel spokes will not stand solid tires, am thinking of going back to pneumatics if I could do something to make them less liable to puncture, and also lessen their bumping qualities.

Yours truly,
White Lilies, Clewer, Windsor.
August 1, 1900.

W. VANDERBYL.

A MOVEMENT is reported to be on foot in Des Moines, Ia., U.S.A., to establish a line of public motor-vehicles.

THE patents of the General Electric Automobile Company were sold by auction in Philadelphia on 11th July for £5,800, in order to satisfy the claims of creditors.

MESSRS. WILLIAM H. BURGESS have changed their offices to 21, Charterhouse Street, E.C., and have secured a warehouse in Steedman Street, Walworth, near the Elephant and Castle.

LICENCES have thus far been granted in Chicago to six lady operators of motor-vehicles. No licences to run steam or petrol carriages have thus far been granted, neither of the latter being considered safe in the unmechanical hands of feminine drivers.

A HERNE BAY cycle firm which is devoting attention to motor matters is Messrs. Root and Clarke, of Station Road. One of our staff called there the other day and found them engaged on the construction of a two-seated vehicle to their own designs. This being the busy season in the cycle trade it is probable that the completion of the machine will be somewhat delayed. The firm are well equipped to undertake repairs to motor-cars and cycles, and at the time of our call had a motor-trike and an "Esculape" voiturette on hand.

It is the intention of Collector Bidwell to institute a service of Locomobile cars between the Appraiser's stores and the Custom House in New York. At present two cabs are used to convey the invoices from the Custom House to the Public Stores. By the installation of one Locomobile, which will make regular trips to convey the official messenger with invoices, it is expected a better service will be given. Collector Bidwell himself has for some time been using a private steam-car to convey him to and from the Custom House.

WHAT is described as the first international automobile tournament ever held in America opened at Newhaven, Connecticut, on the 25th ult., and was attended by thousands of spectators. Over one hundred racing automobiles owned by millionaire amateurs and professional *chauffeurs* were entered for competition, and fully 200 motor-cars were on exhibition from nearly all the leading American and foreign manufacturers. Skinner, the American champion, Wridgway, the English automobilist, and Champion, the famous French *chauffeur*, took part in the contests.

THE American Consul-General at Frankfort, in reporting to the State Department at Washington, states that the Spuyer Automobile Company organised last year has five automobiles in use. They are propelled by a petrol motor in front of the vehicle, of 10 h.p., and were built by the Daimler Company, of Cannstatt. Each car is capable of carrying twenty-eight passengers, and the company has a contract with the Post Office Department to carry the mails to Dudenhofen, Geinsheim, Hohnofen, Hartausen, Mechtersheim, Otterstadt, and Waldsee—two to ten miles away. In the five months since starting more than 40,000 passengers have been carried.

THE PARIS-TOULOUSE RACE.

(From Our Own Correspondent.)

AS in the case of the International Cup event all the automobile world was kept in suspense up to the last moment as to whether the Paris-Toulouse-Paris course would or would not be decided, a proceeding which assuredly renders the holding of such a race infinitely more dangerous than is the case where ample notice is given and organisers, competitors, and public alike permitted to complete their arrangements leisurely. The extreme indecision of the authorities is difficult to explain, and for their own reputation it is to be hoped that any future applications received by them will be dealt with decisively one way or another. It was largely due to their vacillating manner of dealing with the question of the International Cup race that the arrangements on that occasion were so woefully incomplete, and although no very serious complaints have been made under this heading with regard to Paris-Toulouse, still the arrangements were certainly prejudiced and the organisers greatly handicapped by the policy of indecision adopted by the authorities. It was only at 1.30 in the afternoon of Monday, the 23rd ultimo, that Monsieur Waldeck-Rousseau, Minister of the Interior, informed Monsieur Jeantaud, the manager of the automobile sections of the Paris Exhibition, that the event might be decided, and the news spread so rapidly that soon all the automobile world of Paris knew of it. Organised by the Automobile Club of France on behalf of the Exhibition, this Paris-Toulouse-Paris race was *dolé* with money prizes amounting to no less than 47,000 francs, or some £1,880, in addition to medals and similar souvenirs of the event. No fewer than nine prizes of the total value of £1,200 were allotted to the big car category, these ranging from £320 for the first car home to £20 each to those finishing eighth and ninth. Seven prizes were offered to the *voiturettes*, the winner taking £160 of the gross total of £360. For the motor-cycles thirteen prizes were put up, and of the total value of £320 the first arrival had the right to £80. Prizes worth winning, I think I hear you say. Yes, but requiring winning also, I can assure you. The selection of the route gave rise to numerous difficulties, and it was only after several changes that the following was finally decided upon. Starting from Montgeron on the road to Fontainebleau, the course led via Melun, Fontainebleau, Montargis, Gien, Bourges, Issoudun, Chateauroux, Limoges, Périgueux, Bergerac, Agen, Castelsarrasin to Toulouse, a distance of 733½ kilometres (458 miles). Upon the return journey the total of 733½ kilometres was divided into two stages, the selected halting place being Limoges. The roads, taken as a whole, were excellent, but the organisers would have done better to have selected the Marmande and Tonneins route between Bergerac and Agen, as that actually followed, via Bouniages, Castillonnes, Caucon, and Saint Antoine is dangerously mountainous.

The passage of the racers through the towns was regulated by a cyclist riding before each vehicle, a method which ensures the safety of the inhabitants. The event called forth quite an exceptional number of entries, no less than seventy-six all told sending in their names. This total was made up by twenty-seven cars, fourteen *voiturettes*, and thirty-five motor-cycles, a motor-bicycle figuring in the ranks of the last mentioned class. The sealing of the competing cars was effected on Tuesday, the 24th ultimo, before the doors of the Automobile Club in the Place de la Concorde, the parts actually sealed being—on the cars, the axles, and the hubs; on the *voiturettes* and motor-cycles, the motors, the frames, the hubs, and the differential shafts. This work accomplished, the majority of the competitors dispersed to make their final arrangements, and the next meeting was at the *contrôle de départ*.

This, originally fixed at Montgeron, a small village situated on the P.L.M. line was at the last moment transferred to Lieusaint, some 10 kilometres nearer to Fontainebleau, with the result that many enthusiasts, who had travelled out by train from Paris to the former place, were there hopelessly stranded, local trains at two o'clock in the morning being as rare on the P.L.M. as on most other railway lines. The fact is that, by reason

of the stringent regulations now enforced, the starts and finishes of big races are of necessity located very far afield, with the result that, unless the owner of an automobile, one has great difficulty in reaching the desired spot, more especially when one has to be there by about three o'clock in the morning. In spite, however, of all the trials and tribulations to get there, some six hundred spectators were congregated together at the railway level crossing at Lieusaint when, at 3.55 a.m. on Wednesday morning, the 25th ultimo, M. Gaudichard gave the starting signal to M. René de Knyff, whose big Panhard car was the first of those inscribed on the list of entries. A couple of minutes later M. Voigt, driving M. Charron's winner of the Gordon-Bennett cup, got under weigh, and then followed MM. Girardot and Giraud, each driving similar types of cars. A Mors champion then followed, M. Hourgières, mounted upon a car said to be even faster than that of M. Levegh. The latter himself came after, and then after Comte Boson de Périgord, driving a Panhard, Gordon-Bennett type, followed the Belgian contingent headed by M. Jenatzy, M. Pinson on this year's Panhard racer, de Turckheim, Brillié, de Lorys, Cuchelet, Ravel, Edge, Gauveau, Huguet, and Antony completed the list of starters in the car category, while in the *voiturette* section the following got under weigh:—MM. M. Renault, L. Renault, G. Grus, Mercier, Corve, Cottereau, Camus, and Schrader. The motor-cyclists were MM. Osmont, Tart, Gasté, Bonnard (motor-bicycle), Bardin, Testé, Gleizes, Collignon, Bardoux, Levasseur, Joyeux, Laurens, Demester, Marcellin, Béconnais, Loste, Coindet, Villemain, Perrault, Battaiellie, Deliclé, Clément, Durand, Geo, Caillé, Vial, Fournier, Deckert, and Ollier. The first noteworthy incident *en route* was the closing of the road to the racers between 6.2 a.m. and 8.15 a.m., by reason of the firing school at Fontainebleau, but due note was taken of the competitors' arrival, and the corresponding allowances made. At Fontainebleau the leaders in the three categories were René de Knyff, L. Renault, and Tart. At Gien, 113 kilometres (70½ miles) from the start, de Knyff was leading Giraud and Hourgières; L. Renault was still first in his class and Testé and Gasté were the pioneers of the motor-cycle section. As the day advanced so did the heat increase, until the blazing rays of the sun began to work havoc among the tires, and without exception the racers had their troubles. Bad luck awaited Mr. S. F. Edge and the Hon. C. S. Rolls on the 16 h.p. Napier. Just before the start they had trouble with the water circulation. They succeeded in remedying this, and overhauled several other competitors, when the electric ignition went wrong. The car was not fitted with lamp ignition as an alternative, as Mr. Edge's experiences with electric ignition had been so fortunate that he had pinned his faith to that alone, and it was hard lines that it should fail him at such an important moment. At Bourges (178 kilometres) de Knyff had dropped back into fourth place, Giraud, Voigt and Levegh preceding him. L. Renault still maintained his advance, and Testé had succeeded in gaining eleven minutes on Gasté, who was lying second. Hourgières and Girardot had broken down. Some 45 kilometres further on, that is to say at Issoudun, Levegh held a nineteen minutes lead over Voigt, de Knyff being third. The fortunes of the race fluctuated tremendously, for burst or punctured tires were quite the order of the day, and no man was safe to guard his position any length of time. Levegh only experienced punctures—as if they were not enough—and succeeded in augmenting his lead, but the others changed positions continually as the result of more serious troubles. The order of the leaders at Villeneuve-sur-Lot, 582 kilometres (364 miles), was as follows:—

	H. M. S.		H. M. S.
1. Levegh	... at 2 55 11	2. de Knyff	... at 3 12 53
3. Pinson	... at 4 20 44	4. Voigt	... at 4 38 9
5. Testé	... at 4 39 4	6. Giraud	... at 4 40 34

It was here that de Knyff abandoned the race, as the result of continual punctures, and the look of disgust on his face when, after the finish of the race, I recalled the circumstances to mind was worth going a long way to see. Levegh was never headed, and ultimately pulled up at the finish, some 10 kilometres outside

Toulouse, at 5h. 18min. 25sec., having covered the 721½ kilomètres from Lieusaint in 13h. 13min. 25sec. The crowd had a long and impatient wait before the second man put in an appearance, this being Voigt, whose time was 15h. 24min. Giraud next appeared upon the scene, but having taken only 14h. 58min. 34sec. to cover the distance he was classified second before Voigt. The final classification for the first day was eventually completed as follows:—

CARS.—Levegh, 13h. 13min. 25secs.; Giraud, 14h. 58min. 34sec.; Voigt, 15h. 54min.; Pinson, 15h. 16min. 21sec.; Antony, 16h. 19min. 24sec.; Turekheim, 21h. 10min. 17sec.; Brillié, 26h. 42min. 5sec.; Ravel, 29h. 53min.

VOITURETTES.—L. Renault, 21h. 34min. 55secs.; Schrader and Oury, 30h. 7min.

MOTOR-CYCLES.—Testé, 14h. 40min. 32sec.; Collignon, 17h. 11min. 45sec.; Bardin, 17h. 13min.; Gasté, 18h. 44min. 52sec.; Gleizes, 24h. 32min. 19sec.; Demester, 24h. 42min. 10sec.; Fournier, 29h. 53min.; Vial, 32h. 44secs.

Hourgières, having a "seized" differential, spent the night at Limoges, travelling on to Toulouse on the Thursday morning.

M. Renault ran into a wagon when within a few kilomètres from the finish, and Cottereau also met with an accident, neither racer, however, suffering any injury, but both cars being badly damaged. So ended the first stage, and during the following day the *chauffeurs* were afforded an opportunity of a little repose during the time that their mounts were on exhibition at the Pré-Catelan. A very pleasant *réunion* took

place in the evening, the competitors being the guests of the Automobile Club Toulousain. The following morning, before a very considerable crowd, M. Huet sent all the racers named above, with the addition of Hourgières, on their way, the first to leave at 6.20 a.m. being Levegh, who, however, after travelling a couple of hundred yards, punctured a tire and lost a full quarter of an hour in effecting repairs. The last to leave were Schrader and Oury at 7.49 a.m., by which time the earlier departures were in the vicinity of Moissac. At Agen, 109 kilomètres from Toulouse, the route was fairly swarming with *chauffeurs* and cyclists anxious to witness the passage of the mighty racers. The first of these to arrive was Voigt, who came in at 8.13 a.m. Nine minutes later it was the turn of Levegh, and then followed Giraud and Pinson. The last arrival at Agen was de Turekheim, and he made a four hours' halt to repair his radiators. At Villeneuve-sur-Lot (139 kilomètres) Voigt still conserved his advantage of nine minutes on Levegh, and Giraud, who was suffering from a damaged hand, had lost a couple of minutes in 30 kilomètres. The same condition of affairs existed at Bergerac, as also at Périgueux (248 kilomètres), and although Levegh gained a little between that town

and Limoges he had to rest content with second place, nine minutes behind the leader—and second place, too, only so far as the order of finishing was concerned, for the official category returned him as third, the second place being occupied by Pinson. This official list for the second stage of 351 kilomètres was as follows:—

CARS.—Voigt, 5h. 43min. 49sec.; Pinson, 6h. 1min. 48sec.; Levegh, 6h. 11min. 1sec.; Hourgières, 6h. 14min. 15sec.; Giraud, 6h. 14min. 50sec.; Antony, 6h. 37min. 46sec.; Ravel, 6h. 47min. 27sec.; Brillié, 8h. 54min. 2sec.

MOTOR-CYCLES.—Testé, 6h. 45min. 55sec.; Demester, 7h. 28min. 29sec.; Collignon, 7h. 29min. 14sec.; Gleizes, 8h. 5min. 13sec.; Bardin, 8h. 20min. 32sec.; Gasté, 8h. 59min. 4sec.

VOITURETTES.—L. Renault, 8h. 47min. 1sec.

For the two days over a total distance of 1,074 kilomètres (671 miles) the return was:—

CARS.—Levegh, 19h. 24min. 26sec.; Voigt, 20h. 45min. 43sec.; Giraud, 21h. 13min. 24sec.; Pinson, 21h. 18min. 9sec.; Antony, 22h. 57min. 10sec.; Hourgières, 36h. 32min. 4sec.; Brillié, 35h. 32min. 4sec.; Ravel, 36h. 40min. 27sec.

MOTOR-CYCLES.—

Testé, 21h. 26min. 27sec.; Collignon, 24h. 42min.; Bardin, 25h. 35min.; Gasté, 27h. 43min. 4sec.; Demester, 32h. 10min. 39sec.; Gleizes, 32h. 37min. 13sec.

VOITURETTES.—L. Renault, 30h. 21min. 56sec.

Vial, the motor-cyclist, did not finish, as, when at Maison-Rouge, a small village near to Périgueux, he came a bad cropper over a dog, and

was conveyed in an unconscious condition by Schrader and Oury to the hospital at Thiviers, where at the time of writing he is still lying. At Limoges the local cycle club did the honours during the evening, and at an early hour the following morning all the world was astir to see the racers set out on the last stage of their long journey. Levegh had again the place of honour, and his start was effected at 4.15 a.m., exactly half an hour before Voigt, who followed him. The others followed at irregular intervals, and it was not until 7.18 a.m. that the whipper-in made a start for Lieusaint. Levegh had, at Chateauroux (120 kilomètres) considerably increased his advance, Giraud, Voigt, and Pinson following him in the order given. At Issoudun (147 kilomètres) the leader lost half an hour in effecting repairs, and it was about here that Fournier had a curious experience, for his motor took fire and for a minute or so burned gaily. Levegh still led by twenty-five minutes at Bourges (183 kilomètres), and it was remarked that Giraud's car carried a front spring badly damaged and bound with thick cord. For the rest of the journey a desperate struggle took place between Pinson and Voigt, first one and then the other leading, with Levegh, however, always ahead. In the neighbour-

THE JAMES-ANDERSON STEAM OMNIBUS, BUILT ABOUT 1829. (See page 372.)

hood of Gien a nasty accident occurred to Hourgières, for at the moment when he was passing a wagon the horse took fright, and as a result of the collision the car was overturned and travelled upwards of thirty yards upon its side. Hourgières broke a rib against the brake lever, and his mechanic escaped with nothing worse than a shaking. At Montargis (295 kilomètres) Giraud punctured a tire and effected repairs, aided by De Knyff, Charron, and Girardot, who had run out from Paris in a 12 h.p. Panhard. Through Nemours, Fontainebleau, and Melun, right up to Lieusaint, Pinson and Voigt struggled hard for second place, and the victory would probably have gone to Pinson had not his clutch commenced to slip when 10 kilomètres from home. The competitors arrived very late at the finish, for we, who had got up at 5.30 a.m., and journeyed out from Paris by train to Lieusaint and walked 6 kilomètres from the station to the scene of their arrival, had to wait patiently during an hour and a quarter until the first, Levegh, put in an appearance. He arrived at a great speed and smothered in dust. Having signed at the *contrôle* he waited until the succeeding cars had appeared upon the scene, his admirers meanwhile attaching a magnificent bouquet to the splash-board of his racer. About twenty-five minutes later we were treated to a real sensation, for Voigt arrived at full speed, hotly pursued by Pinson, a bare minute separating the two at the finish. A back spring of the former's mount was broken, and the vehicle had settled well down to the right; Pinson's car only showed traces of the tremendous strains to which it had been subjected in the damaged footboards, nearly all of which were broken. A long, long wait then ensued, and gradually the little group of spectators, which included Mr. Mark Mayhew and Mr. Frank H. Butler, commenced to diminish. Mr. Butler was accompanied by his daughter, Miss Vera Butler, who had driven his Panhard car from London to Paris, thus achieving the distinction of being the first lady motorist to steer an automobile between the English and French capitals. M. and Mme. Albert Lemaitre, on a Peugeot racer, Comte de Dion and M. Bouton on a voiturette, Comte Boson de Périgord, driving a Panhard, and many other notabilities in the automobile world only remained long enough to see Giraud arrive at 12.43 before setting out for Paris. MM. René de Knyff, Charron, and Girardot made a flying visit to the *contrôle*, and carried off the Comte Chasseloup-Laubat to lunch at Montgeron. As for the rest of us, we just waited on for some time, but no results of our patience being forthcoming, we also turned upon our heels and left the officers of the *contrôle* all alone in their glory to watch and to wait for the errant *chauffeurs*. Their complete return was as follows:—

CARS.—1, Pinson, 6h. 44min. 18sec.; 2, Voigt, 7h. 16min. 26sec.; 3, Levegh, 7h. 19min. 27sec.; 4, Giraud, 7h. 32min. 44sec.; 5, Antony, 9h. 41min.; 6, Ravel, 9h. 50min.; 7, De Turckheim, 9h. 5min.; 8, Brillie, 14h. 17min.

MOTOR-CYCLES.—1, Fournier, 8h. 13min. 43sec.; 2, Bardin, 8h. 13min. 51sec.; 3, Testé, 8h. 25min. 26sec.; 4, Gasté, 8h. 35min. 47sec.; 5, Collignon, 8h. 39min. 10sec.; 6, Gleizes, 9h. 32min. 48sec.

VOITURETTES.—1, Renault, 10h. 4min. 50sec.

The final classification for the entire race was:—

CARS.—1, Levegh, 26h. 43min. 53sec.; 2, Voigt, 28h. 2min. 7sec.; 3, Pinson, 28h. 3min. 16sec.; 4, Giraud, 28h. 46min. 6sec.; 5, Antony, 32h. 38min.; 6, De Turckheim, 43h.; 7, Ravel, 46h. 30min.

MOTOR-CYCLES.—1, Testé, 29h. 51min. 53sec.; 2, Collignon, 33h. 21min. 16sec.; 3, Bardin, 33h. 48min. 51sec.; 4, Gasté, 36h. 18min. 51sec.; 5, Gleizes, 42h. 9min.

VOITURETTES.—1, Renault, 40h. 27min. 40sec.

From Lieusaint the competing cars were driven by their owners to the Vincennes annex of the Exhibition, for one of the conditions governing the contest was that the competitors should expose their racers during the week following the finish of the *course*. The presence of the cars has proved a distinct attraction at Vincennes, and on Sunday last, in spite of the rain, a great number of people journeyed out by the new Metropolitan Railway expressly to see them. Needless to say, the flower-bedecked winner came in for considerable attention, and its rakish lines excited much favourable comment. A number of well-

known automobilists were also in evidence, for the jury of the Exhibition contests were in conference under the presidency of M. Forrestier, so the day was quite an automobile one. With this event automobile racing is likely to remain quiet for some time to come—indeed, it would not surprise me if it proved to be the last long-distance *course* of the year. Comparatively little difficulty should be experienced in obtaining the necessary permission for the hill-climbing contests, but I fear that but little chance exists of deciding the Paris-Ostend or any similar event.

THE KAYSER MOTOR-VOITURETTE.

THE latest German cycle-making concern to turn out a motor-voiturette is the Pfälzischen Nahmaschinen und Fahrradfabrik Gesellschaft (vorm. Gebrüder Kayser) of Kaiserslautern. The company have been building motor-cycles for some time, but only recently took up the construction of cars. The accompanying illustration gives a general view of the two-seated vehicle they are now putting on the market. It has a tubular frame, on which is mounted at the front a Kayser vertical petrol engine under a perforated metal bonnet. In the particulars issued by the company no mention is made of the horse-power of the engine, but they state that it is of sufficient capacity as to drive the car at a speed of 30 kilomètres an hour on ordinary roads and of enabling the car to mount all ordinary hills. The ignition of the explosive charge is effected electrically, the company employing a system of their own for which they claim several advantages. As for the cooling of the motor, the cylinder walls are fitted with radial ribs, while the explosion chamber is provided with a water jacket; the circulation of the water is maintained generally on the thermo-syphon arrangement, but if desired a pump and cooling coil can be fitted.

Coming now to the transmission gear, this is a combination of belts, cogs and chains. Three speeds are available—7½, 15, and 30 kilomètres per hour. The motor transmits its power by a single belt to a countershaft. On the latter is a train of cog-wheels, any one of which can be made to mesh with similar wheels on the differential shaft, which is connected to the rear axle by the usual duplicate set of chains and chain-wheels. The steering is controlled by a small hand wheel on a vertical standard, on which the variable-speed control handles are mounted. There are both hand and foot brakes, the former acting on the tyres and the latter on the differential shaft. The levers controlling the foot brake are so arranged that when it is applied the driving belt is at the same time slipped on to the loose pulley, thus throwing the engine out of gear from the transmission mechanism. The crank shaft of the engine and the variable-speed gear work in oil-containing cases, while the road wheels, which are of the cycle type, shod with pneumatic tyres, are mounted on ball-bearings. The car is about 7ft. long by 4½ft. wide, and weighs complete about 6 cwt. The petrol tank has a capacity sufficient for a run of about 150 kilomètres.

The Stutzman Automobile Company has been organised in Williamsport, Pa., U.S.A., with a capital of £10,000.

THE PANTZ MOTOR-WAGONETTE.

IN our issue of January 26 last we gave an account of the system of motor-cars introduced by M. Ch. Pantz, of Pont-à-Mousson, France, the feature of which is the mounting of the motor and the whole of the transmission gear on a distinct frame, which can be detached from one vehicle and applied to another. The accompanying illustration shows a seven-seated wagonette lately constructed on this system. The frame carries a two-cylinder petroleum-spirit motor of 6 h.p., provided with electric or tube ignition and Longuemare carburettor. Upon the motor-shaft are mounted three pulleys, of different diameters, transmitting power by means of belts to corresponding pulleys on the countershaft. Each of the pulleys on the countershaft comprises a fast pulley and an idle one. At the end of the countershaft is a pinion operated directly by the shaft for forward motion, and by a system of internal gear for the reverse. When the frame, with motor and gear, is placed in a vehicle this pinion engages with a gear which transmits its motion to a second counter and differential shaft on the vehicle.

Each side of the frame has two bolts, the heads of which fit in grooves in the framework of each vehicle in such a manner that the pinion engages with the gear of the vehicle, which trans-

mits the power to the rear road wheels. The motor and machinery being in the proper position it is merely necessary to fasten the four bolts to render the whole vehicle firm and safe. The speed mechanism is then connected to rods which are attached to the controlling levers. It is claimed that when these bolts are all securely set the vehicle is almost as firm and solid as though the motor had been an integral part of the vehicle. Each car has its own water-cooling device, steering and control levers and its special transmission, carrying the differential and the pinions operating the transmission chains.

To facilitate the change of the motor and transmission gear from one vehicle to another, a stand is provided having grooves similar to those in the vehicles, so that when the motor apparatus is drawn out of the vehicle it rests upon the stand and can easily be inspected and repaired. The stand has an arrangement whereby its grooves may be adjusted to the same height as those of the vehicle. The entire operation of changing the motor and transmission frame from one vehicle to another requires, it is claimed, but a very few minutes.

THE Canford Cliffs Motor Omnibus Company, Limited, have been fined at the Bournemouth Petty Sessions for committing two breaches of the bye-laws at Parkstone: by erecting a building without having deposited plans, and further with building without the approval of the Town Council.

THE TRIUMPH OF THE TURNPIKE.

THE opening of a brand new Border hotel on a lonely country road ten miles away from anywhere deserves more than a passing notice. The event is full of significance as an index of the change that is taking place on our country roads. Already a great stream of life is flowing along them. The cycle has begun to give them back to us, and the motor, says the *Scotsman*, will complete the gift. Macadam, after being clean outpaced by Stephenson for more than fifty years, is coming away with a big spurt, and is promising to make a great race of it for the pre-eminence in the coming century. The opening of this inn is only typical of what is happening throughout the length and breadth of the country, albeit in humbler and less striking significance. Everywhere the cyclists' needs are being waited on. Lonely wayside inns are blossoming into Cyclists' Rests. And cottages by the roadside, away up on the wine-red moor, that a score of years ago would have only a carrier's cart and an occasional wayfarer to tell them of the great busy world outside, have now their finger on the throbbing pulse of humanity, and are prescribing milk and biscuits from their windows for the suffering pilgrim of the road.

And all this we are fain to believe is but the curtain-raiser, the prelude to the play. Enter Hamlet—on a motor-car! To quote from the *Spectator*—"The motor-car will, in fact, do more fully what the bicycle began—i.e., give the nation back its roads." The motor has really come to stay—so most of us are persuaded, after the thousand miles' exhibition trial. In France for some years now they have recognised this fact; but that only goes to prove what Matthew Arnold failed to do, though he asserted it often enough—the greater readiness of our Gallic neighbours to take in new ideas. Already cars are reported there to be doing something not far short of fifty miles an hour on the highway. And this opens up a whole world of possibilities, every one of them a triumph, for the immediate future of our turnpikes; provided only that the county councils bestir themselves and give us a better surface on our roads.

To own a motor is still, of course, fame, and to hire one for the day confers distinction, and makes the occasion something of a "ploy." But, as a matter of fact, this latter at least is now within the sphere of practical politics. Already we who dwell in country parts have had our friends from town drive in their motor-car to our gates; and before long we look to see them commonly, quite as a matter of course, just as the cyclist drops in to-day. Once only the ownership of motors becomes a rule rather than a striking exception, and the hiring of them becomes a commonplace; it requires no prophetic vision to see the flood of travellers that will be surging along every country road. On business—e.g., to accomplish a twenty or thirty miles cross-country journey and back again in the same day—who will ever dream of doing it by rail when his motor stands solicitous at the door? At his own good pleasure, having breakfasted at his usual hour and leisurely, he steps into his car, and in something under a couple of hours he is pulling the door bell at his destination. No bother of early rising to catch the only suitable train; no bolted breakfast and hurried scamper to the station; no changing of trains or anxiety about catching connections; no fuss, or strain, or worry. But, instead, a bracing spin at your own time and convenience, returning by a different road if you will, and the whole thing accomplished in not more time than the railway journey would require.

Business becomes pleasure on terms like these. But think of highway travelling for pleasure pure and simple—on holiday, e.g., what more enjoyable week or fortnight could one imagine than to go spinning along, in congenial company, thirty, fifty, eighty miles a day, just when and where and how you will; spending a useful morning amid the old castle's ruins, or going over the little country church, with "its Norman arch, its brasses black and red"; dawdling a long, lazy afternoon up on the lonely moorland, where the whaups are crying, and where the smell of the peat reek floats down the breeze with the barking of the shepherd's dog; "doing" some interesting country town; going

over some famous historical scene; spending a night or two with old friends, a day or two on some familiar links, or on some favourite stream? Why, the prospect fairly thrills one to the marrow! Would that the Muse of the Road, gently considerate, should deign to tip this halting pen as with fire, so that, according to the needs of the occasion, the glory of the new life and the new travel on the old road should be all fittingly set forth.

"Five-and-thirty years ago the glory had not yet departed from the old coach roads; the great roadside inns were still brilliant with well-polished tankards, the glances of pretty barmaids, and the repartees of jocose ostlers; the mail still announced itself by the merry notes of the horn." Thus George Eliot's opening notes in her well-known swan song of the dying stage-coach, sung now almost thirty-five years ago. Again the Golden Age returns—that age that we had with us seventy years ago. The old order changeth, yielding place to new; and the new, as so often, is just the old—with a difference. The knight of the red face and round hat, in his coach peagreen or yellow, floated away out of our grandfather's sight into some island valley of Avilion, returns again to his familiar haunts along the King's highway. But in his hands this time it is a steering-wheel he holds, no longer ribbons; an oil-can, not a whip.

And what of that other—the true Knight of the Road, with masked face, darkly lurking in the lonely places? Will a new order of Dick Turpins arise to give an *aliquid amari* to the cloying sweets of highway travelling—a spice of danger to the glorious sport? Already we read of burglars on the other side of the Channel escaping with their booty on a motor-car. Is this the first stage in the development of the modern highway-man; the rider whose new Black Bess will be geared to not less than eighty miles an hour; the social reformer that will remember the poor, while he relieves the bloated rich of their ill-gotten gains; the gallant that will call beauty to foot a measure with him on the lonely heath, and then, swift as the wind, vanish down the glen? Who shall tell? Let no one prophesy unless he knows. Perhaps, as the old inn, and the old coach, and the old driver are to be so changed, so he, too, will wear another garb. Shall we find him at the receipt of custom; no longer now the ally of the landlord (as was so often suspected), but the landlord himself?

LORD SAVILE has just had delivered to him a new voiturette.

THE initial run of the Buffalo Automobile Club was held on the 8th ult. Eight vehicles participated, and the affair was an unqualified success.

THE Speedwell Electrical, Motor Car, and Cycle Company, Reading, whose premises were recently burnt out, has taken more convenient premises at the junction of Minster and Broad Streets.

At Londonderry, on Saturday last, Mr. J. W. Stocks gave an exhibition of the hill-climbing powers of his Ariel motor-tricycle by making a trip up Ship Quay Street. The performance was witnessed by a large concourse of people. Subsequently he made a few speed trials at the Brandywell cycle track.

THE "IDOLE" MOTOR-QUADRICYCLE WITH WATER-COOLED MOTOR.

USERS of motor-quadricycles will be interested in the description of the machine which has lately been put on the market by M. J. Théodore, of 21, Rue Brunel, Paris, and of which an illustration is given herewith. The feature of the machine, which has been named "L'Idole," is the employment of a water-cooled engine in place of the usual air-cooled type. The motor employed is an "Aster" of 3 h.p., the ignition being electrical. A specially-shaped tank is carried behind the rear saddle; this tank is divided into two compartments, one holding $1\frac{1}{2}$ litre of lubricating oil and the other 13 litres of water, the circulation of the latter being on the thermo-siphon arrangement. A small radiating coil is fitted which enables a long distance to be run without it being necessary to renew the cooling water. The petrol tank is carried within the frame and is connected up to a Longue-mare carburettor. The motor is adapted to be started by means of a detachable handle, so that the operation of pedalling is rendered unnecessary except when ascending steep hills. The front seat can be readily detached, converting the vehicle into a single-seated quadricycle.

THE "IDOLE" MOTOR-QUADRICYCLE.

A BENZ car and an Ariel quadricycle are to be seen daily running about New-quay.

FRISWELL'S AUTOMOBILE PALACE, LTD., is the title of a new company to be formed with a capital of £40,000, divided into £20,000 6 per cent. preference shares and £20,000 ordinary shares. £10,000 will be reserved for working capital.

A FIVE miles motor race on the grass was included in the Chichester Club's evening cycle race-meeting on Thursday last week, with the result that Mr. J. D. Foster, one of the club's oldest racing members, came in first, Mr. T. S. Adcock, another veteran, being second. There were four entries, the winner having four hundred yards start, Adcock being on scratch. Time, 12min. 15 1-5 sec.

MR. WILLIAM K. VANDERBILT, jun., to whose 30 h.p. Daimler we made reference a fortnight ago, has been arrested for driving his car at a furious speed through Milton, a suburb of Boston, U.S.A., and was fined 15 dols. at the local police-court. It is stated that Mr. Vanderbilt made a flying trip from Newport to Boston, a distance of 75 miles. The trip was made in 2 h. 47 min., the speed averaging 30 miles an hour, except in and near Boston, where he slightly exceeded the legal limits.

We have received a copy of "Le Concours de Moteurs" (Paris: Vve. Ch. Dunod), which is a full account of the trials conducted by our French contemporary *La Locomotion Automobile* from October to January last, of engines and the powers developed by them, as well as the separate series of trials as to the actual power obtained off the road wheels. It is from the pen of M. Gaston Sancier, and is a most interesting work. Preceded by a preface by M. Pierre Giffard, the work includes chapters on motor and vehicle tests, followed by a detailed account of the results obtained from the various engines and cars subjected to trial. The details are set forth clearly, and are accompanied by illustrations, so that they have a permanent interest.

THE IRISH MOTOR TOUR.*

(From Our Own Correspondent.)

WE reached our headquarters in Kerry, as already described (Derrynane being the place, and one of the sweetest spots in Ireland by the same token). We confined ourselves to circular runs in the neighbourhood for a few days, as the strain of the four long journeys was enough to make us wish for a rest, or, at least, something as near to a rest as the enthusiastic motorist will allow. We put in from about 30 to 60 miles daily, the trips being amidst delightful scenery on the Atlantic seaboard.

Then, on the 24th ult., we struck camp and moved homewards. The greatest task of the tour had to be done this day, it being on the cards that we should climb Ballaghbeama Pass. There was no necessity to do this, but its being the severest defile in Ireland seemed to recommend the feat. Our cars were quite new, and the owners probably thought it interesting to test them at their maximum. Personally, if I had a car I would prefer trying it on the roof of a house or up a flight of steps. Ballaghbeama is vertical enough in all conscience. As a roadway it is practically disused, and grass and rough, loose stones cover most of that surface. Very narrow is it also, and most unpleasantly perched alongside a little precipice. From a scenic point of view there is nothing to equal it in the three kingdoms. The mountains through which it squeezes itself are nearly 3,000 ft. high, and the road comes pretty close to the top ere it ceases climbing.

Once moving on the enterprise we had to see it through. The narrowness and tortuousness of that road-bed left all hopes of steering backwards out of the question. The great wall of towering rock which bordered one side of that roadway gave little chance of fetching up against it if the worst happened, and we had to slow across the road to prevent running away. It was a grand struggle up that snaky slope, and about as finely balanced one as I would care to risk myself in again. The prospect of tumbling over a precipice with a motor-car immediately following is about as cheery as being boxed up in one which has started to run backwards down a mountain slope, with the other car blocking the way round the next corner. The breaking of a chain, or the failure of a burner would have given us Hobson's choice of these fates.

However, the Daimler won the day after a tough fight, and having seen Mr. Mccredy's car reach the summit safely, we had less misgivings about Dr. Colohan's vehicle, as it has proved itself a stronger hill-climber than any other Daimler in Ireland.

To return to our motors. We felt we had made an epoch in mountain motoring as we stood triumphant on the hill top. Whilst the engines got a cooling spell we had a better opportunity of examining the grand scenery which pressed close round us on every side. But it was not till we moved downhill and came to the tableland at the foot of the pass that we gained a true conception of the magnificence of our surroundings. The highest and grandest mountains of all Ireland congregate there, gaunt and stately. For miles and miles our road wound along, by their bases, through a lovely bogland valley. Genial sunshine and a blue sky prevailed to make the pictures perfect. Right into Killarney one view more beautiful than another followed, the sunset colourings over the lakes being specially impressive. It was the grandest view of the entire tour and dwarfs all the rest. We could only find its equal amongst the Alps.

From Killarney next morning we journeyed through county Cork, and never was a more painful change made. The roads became atrocious and the scenery poor. So bad was the surface that we had to keep on our low speeds, and even then we were thrown about so much that we fell into the dumps, and felt no interest in the scenery. Everything had been perfect on the previous day; now the world was quite a miserable place. The very cars sulked.

It was late in the evening when we reached the lovely Blackwater district, and even if the light had favoured we were too jaded to appreciate the place as we should. We put up for that night at Lismore, and next day made Waterford, where

we were met by that enthusiastic motorist Mr. Goff. A long journey had still to be done ere Gorey, in co. Wexford, was reached. Thence we left on Friday for Dublin and arrived that night, encountering a thunderstorm when near home. It was rather fortunate that we hurried on the latter portion of the journey, as the weather broke up immediately.

Our total distance comes to over 700 miles, and we have accomplished this in thirteen days of driving. The mishaps were nil, and the total delays amount to less than thirty minutes to adjust the governor spring once and light up burners, which blew out three times accidentally. Since the first day we have almost constantly been hill climbing. Many of the roads we have taken the cars over are utterly unsuited for such traffic by their narrowness and bad surface or gradient. Our average of nearly sixty miles a day has been accomplished without racing or undue hurrying. Indeed, fast pace was impossible on very many of the roads owing to the sharp curves or the severe up-hills. Thus it must be conceded that the cars have been put to a most drastic test. Both the vehicles were quite new, and one of them, Dr. Colohan's, was only ready for the road on the night previous to the trial.

Immense attention has been given to the tour in Ireland, and the satisfactory results have fairly astounded the onlookers. We will be much surprised if the pastime does not rapidly advance as a consequence in the Green Isle.

A CLASS for motor-car drivers has just been started in Charlottenburg by the Grosse Berlin Motorwagen Gesellschaft. Half of each lesson is devoted to technical matters and half to practical driving, the complete course comprising ten lessons.

THE English Motor Club, Limited, has been registered by Mr. G. H. Smith, 64, Holborn Viaduct, E.C., with 200 members, each liable for £1. Object, to promote the use of motor-vehicles for recreation and business purposes. The management is vested in a committee.

"MOTOR PROBLEMS" is the title of a useful little booklet which has just been issued by Mr. C. H. Guest, M.I.M.E., of Draycott, near Derby. It contains a number of useful hints to users of motor-cycles, and also gives particulars of the Guest exhaust valve, valve lifter, two-speed gear, etc.

FIG. 2—REAR VIEW OF FRAME OF RAOVAL CAR. (See opposite page.)

* Concluded from page 360.

THE RAOUVAL MOTOR-CARRIAGE.

IN our last issue we published some particulars of the Raouval motor-carriage, and stated that the vehicle was fitted with a two-cylinder vertical motor of the Pygmée motor, capable of developing from 6 to 8 h.p. A general view of the engine, which works with either petroleum

FIG. 1.—GENERAL VIEW OF MOTOR.

or petroleum-spirit, is given in Fig. 1, while a sectional view is reproduced in Fig. 2. The admission valves are located in the cylinder ends, C C' while passages b b' are formed on the right-hand side communicating with the vaporising chamber. On the left-hand side are passages u communicating with the exhaust valve E E' . The cranks are arranged at

FIG. 2.—PART-SECTIONAL ELEVATION OF MOTOR.

an angle of 180 deg. to each other, an explosion taking place in one of the cylinders only at each revolution of the motor-shaft. Above the crank shaft and driven off it by the spur wheels g g^1 g^2 is the cam shaft F , which at one end is provided with a centrifugal governor H . In the middle of the shaft are two cams, f f' , in continuous contact with which are rollers fixed on the lower ends of the rods e e' . These rods, which pass

through a plate G , serving as a guide, have a slot formed on the face and extending their whole length, small screws passing through the plate G , and projecting into this slot preventing the rods from turning. Just above the plate G , the rods e e' meet and push up and down the exhaust valve spindles d d' . In continual contact with the sleeve of the governor is a pivoted arm h , which at its upper end is rigidly connected to a bar t , extending across the front of the cylinders, and guided by the plate G . On the top of the latter are pivoted two pawls made to work in unison by means of the spring R . Should the speed of the motor become excessive, the governor allows the arm, and consequently the bar t , to move towards the left. This movement brings a stop on the bar t in contact with the pawl i , the end of which is forced into a hole in the end of the rod as soon as the latter reaches the pawl, thus preventing the exhaust valve E from being opened. The two rods e e' do not touch the pawls at the same time, but alternately, so that only one exhaust valve is closed at a time. As soon, however, as the rod e' rises to the pawl i' , the latter slips under the action of the spring r into its hole, thus preventing the exhaust valve E' from opening. When the speed of the motor once more reaches the normal the governor permits the spring R to draw back to the right the bar t ; in doing this the

FIG. 3.—DIAGRAMS OF PROGRESSIVE STEERING DEVICE—RAOUVAL CAR.

stop k' pushes the pawl i' out of the hole in the end of the rod e' , the pawl i at the same time releasing the rod e . Tube or electric ignition is employed as desired; the carburettor adopted is of the well-known Longuemare type, while the cylinders are, of course, water jacketed. The crank and crank shaft work in a dust-proof oil-containing casing A , the ends of which form a bearing—of bronze metal—for the motor shaft. The casing is provided with detachable covers, to render the piston rods and cranks readily accessible. Fig. 3 shows the details of the progressive steering device referred to last week.

THE journey from Biarritz to Madrid has just been accomplished by Count de Cabrillas on a 12-h.p. Peugeot car. The trip occupied three days, and in Spain the route followed lay through a district not previously traversed by a motor-car.

LOOKING in at Messrs. Gamage's dépôt in Holborn, E.C., the other day, we noticed an announcement to the effect that they have a nine-seated Daimler wagonette, which can be hired by the day, week, or for tours by arrangement, and that lessons are also given in motor-driving.

THE Central German Automobile Club has just held a meeting, at which it was decided, in order to celebrate the founding of the club, that a summer festival will be held at Eisenach. A committee has been appointed to make the necessary arrangements for the festival.

THE PROGRESS OF THE AUTOMOBILE.

BY PROFESSOR R. H. THURSTON.

(Continued from page 369.)

THE automobile now finds its way into every part of the civilised, in fact into many portions of the uncivilised, world. Large numbers have been sent to South Africa for use in supply trains, and the transfer of horses to the seat of war in such immense numbers has caused their replacement in London streets by the "autovans," now almost as numerous as were, formerly, the omnibuses, and, it is reported, with a very appreciable economy. Profits on sales of horses and gains by use of the automobile are together adding greatly to the dividends of the companies. In America, electric cabs and other vehicles are coming into use extensively in our large cities, and the Baltimore and Ohio railroad passenger department is about establishing such a cab-service in Washington, with a fifty-cent. fare. A well-proportioned automobile will traverse any respectable road and go wherever the horse can fairly be expected to travel. It should ascend a 10 per cent. grade readily and ride over obstructions that would stall any horse-drawn wagon. Ice may stall it, but snow should obstruct its movements less than those of the horse and its carriage.

Washington insisted on the promotion of national roads and the encouragement of the production of horses for transportation. Hamilton recognised the influence of facilities for transportation in the promotion of the industrial advance of the country, and we all to-day see clearly, as never before, that every new method of improved transportation is a great gain. Motor wagons and carriages have probably now come to stay with us, and the displacement of the horse in commercial work generally, and possibly even in a considerable degree in pleasure travel, seems certain to occur soon. Self-propulsion is itself an enormous advantage and the improvement of the roads by the substitution of effective road-rolling, in the use of the vehicle, for the destructive action of the hoofs of horses is also a larger gain than is commonly realised; while release from the physical defects of the horse used as a motor is, sanitarily and psychologically, hardly less important.

Rated powers of motor-vehicles are often greatly over-stated, and the automobile rated at 2 or 4 or 10 h.p. is often found, under the truth-revealing test of the Prony brake, to be capable of working up to less than two-thirds, sometimes less than one-half, its stated power. On a good pavement, and with a light carriage, $1\frac{1}{2}$ or 2 h.p. proves quite sufficient for any safe speed over any usual city gradients, and a rated 4-h.p. motor may thus not fail in its work under any ordinary conditions, even though far below its rating in actually available power. A correct rating, however, as established by the brake, is essential to a real knowledge of the action of the machine and to its intelligent design and improvement. The correct rating is the power it is capable of exhibiting at any time, and for any length of time, under the brake when at its regular and normal speed, precisely as if in operation in its place in the automobile on the road.

The difference in power required on a level and ascending a hill, or on a smooth and on a rough road, is rarely appreciated by the automobilist-amateur; though familiar, through many trying experiences, to the old hand. Two horse-power, actual and deliverable against the brake, will, on a good road, drive an automobile weighing 750 to 800 lbs. 12 miles an hour easily, but on moderate up-grades the speed will fall to 8 miles or less. In some cases, on a smooth pavement, this expenditure of power may drive the carriage at the rate of 15 and 18 miles an hour on the level. With good speed-changing gear, the engines or motors may be made to deliver their full power at whatever speed of carriage the varying grades may cause the work to be done, and, if one choose, the power available at low speeds, rising a hill, may be made higher than that employed at high speeds on the level. Twelve or fifteen hundred pounds of carriage and passengers may be propelled, on a level, at 20 miles and upward by 4 or 5 h.p.; but a grade rising but 200 feet in the mile will pull down the speed to perhaps 15 miles an hour. Ten h.p. per

ton should give some such figures as the above, if the motor supplies the power for which it is rated, or say a $\frac{1}{2}$ h.p. for each hundred pounds of carriage and load. The actual power required on a very smooth level road, as an asphalted street or a good macadamised suburban road, would be properly not far from 1 h.p. to 500 pounds weight transported, including the automobile itself, for 10 miles an hour, $1\frac{1}{2}$ for 15 miles, 2 for 20 miles, 3 or $3\frac{1}{2}$ for 25, and 4 or 5 for 30 miles an hour. These figures are increased about 25 per cent. for each increase of elevation of one per cent. or of 50 feet to the mile. Four or five per cent. is not an uncommon elevation in even comparatively level countries, and grades of 10 per cent. and upward must be encountered occasionally in hilly districts. An actual 10-h.p. machine, of 1,000 pounds weight, with its load, which may speed up to 30 miles an hour under the most favourable circumstances, may fall to one-third of that speed on a less than 10 per cent. rising gradient.

The wheel resistance alone of a wagon or carriage on the city street may be taken as from 40 pounds per ton on asphalt, to 50 pounds on a smooth cobblestone, and 60 to 75 on macadam pavement, smooth and rough. These figures correspond to about three-quarters of a horse-power at the lower limit, and to one horse and one and a quarter at the higher resistance, at 7 miles an hour, or to from one to one and a-half or three-quarters at 10 miles an hour. One horse-power per ton at 10 miles an hour, for good construction of vehicle and roadbed, may be considered perhaps a fair average figure in city work, and a maximum speed, and three-quarters of a horse power, or a trifle less, at the usual speed of 7 miles, increasing to a full horse-power on rough streets or with very moderate rising gradients. The horse, however, if compelled to work at 7 miles an hour in city work, cannot usually be depended upon to do more than about 20 miles a day, and thus exerts about one rated horse-power for only three hours a day working time.

Automobiles would seem to be less affected, in speed and steadiness of action, by variations of conditions of roadbed than are horses; but precisely why this should be it is difficult to state with confidence. Possibly the inertia of the mass and the steadiness of the former, and the jerky and varying pull of the latter, may account for the difference. But automobile and horse-drawn vehicles are alike greatly affected by variation from a level track, and it is elsewhere shown how both power and pull, as well as speed, are affected, as measured in terms of energy, work, and pull. The automobile, as a rule, maintains a higher average rate of speed than the equine machine and thus utilises a considerably larger amount of power. Where the horse averages 7 or 8 miles, the automobile probably averages 8 or 9, or even 10. The resistance per ton at a given speed, with equally good construction and similar wheel-diameter, should be the same. The weights, however, are not strictly comparable; since the automobile carries its own power and is thus debited with weight in excess by that amount; the weight of the motor in the other case being separately carried on its own feet and, in all usual data, left out of account. Further, the great weight on the wheels of the automobile, where not fully compensated by increased breadth of tire, causes deeper wheel-track and higher resistance per ton than with the horse-drawn apparatus, but the competing automobile will do easily twice as much work per day, in commercial employment, as with the horse, and can, if desired, be kept in action night and day, except that time must be allowed, with electric vehicles, especially, for charging, or, better, exchanging batteries or storage tanks. When the finances of the case are considered, the best automobiles stand far in advance of the best of the older system.

Of the available fuels for the heat-motors, coal and coke are the cheapest, and will presumably be ultimately found the proper fuels for purely commercial use, and the laws against smoke will probably compel the choice between anthracite and coke. The crude oils and the tarry and other by-products of gas-making follow in availability and costs and have advantages in heat-production for the unit weight or volume and also in their convenience. The petroleum is of highest value, and the safest petroleum is most costly and is most troublesome in use in the internal-combustion engine. Heat-contents range from 10,000

to 15,000 *B. T. U.* in the coals, to 20,000 *B. T. U.* per pound, in the oils. Liquid fuel is much superior in stowage, both in condensation into minimum volume and weight and in convenience of handling. Unpleasantness in handling, however, noisome vapours, and their explosive character in the case of the lighter fluids, and, even the noisy combustion, are disadvantages of no small importance. Vaporisers and atomisers are often troublesome, and the heavy petroleum and tarry products do not always work steadily and with certainty.—*The Automobile Magazine.*

bronze, are also very wide and thus assure the motor an operation of long duration without any appreciable wear. Through an ingenious arrangement, a continuous circulation of oil is maintained in the crank casing, and this renders the consumption of the lubricant insignificant and necessitates no surveillance. The ignition is effected either through an electric spark or by an incandescent tube. With the sparking, an extremely simple device, in which but a single cam is employed, permits the speed of the motor to be varied between certain limits. With tube ignition a centrifugal governor acts upon the motor in such a way as to keep the exhaust valves open should the speed become too great. During this period the admission valve allows a small charge of fresh air to enter the cylinder, and the motion of the piston expels the products of combustion, the effect of which is to improve the work of the motor. The water circulation is maintained by a centrifugal pump set in motion by the fly-wheel of the motor. The tension of the pump's friction is regulated automatically through a spring.

M. Bravo is constructing motors of 5 h.p. and 8 h.p. Figs. 1 and 2 represent a six-seated wagonette provided with an 8 h.p. motor with electric ignition. The motor, which is arranged in front, is put in connection with the speed-changing gear through a leather-faced cone-clutch. As may be seen from the illustrations, the gearings are enclosed in a casing, *C*, which receives also a reduction gearing, *r*, that reduces the velocity in the ratio of about 1 to 3. As the angular velocity of the gear is thus relatively low with respect to that of the motor, the changes of speed are effected with great facility, without noise, and in avoiding the

frictions and shocks that are so prejudicial to the duration of the parts. The reverse motion is obtained through the shifting of two bevel gears, *p p'*, mounted upon the differential gear shaft, *M*. For the purpose of avoiding the thrusts due to the changes of level of the frame in violent joltings, the differential shaft is divided into four parts (1, 2, 3, 4), the extreme junctions of which are made by universal joints. The carriage-body is mounted upon the principal frame, *D*, while the motor and the mechanism are fixed upon the separate frame *D'*.

One interesting peculiarity of the Bravo motor-vehicles consists in the dismountable front wheel axle. The head of the tubular axle is formed of a vertical socket, which receives an axis, upon which, through a socket-clutch, is mounted the journal-support, which is held simply by a nut. The weight supported by each journal is distributed over a horizontal row of balls that roll between two tempered steel plates. A large circular nut, which closes the ball-case, permits of the regulation of the play in a perfect manner. A set screw prevents any loosening. In this steering pivot, the pieces having a motion are entirely immersed in the oil with which the box is filled at the time of the first mounting. This process of mounting renders the steering very easy, this being effected through an inclined hand-wheel with a transmission through bevel gearing and rigid levers with a universal joint.

The safety apparatus comprise a hand-brake mounted upon the differential gear and controlled by a pedal; and a hand-brake that acts upon the tires of the rear wheels. An electric interrupter

FIG. 2.—PLAN OF BRAVO CAR.

permits of the instantaneous stoppage of the motor by throwing it out of gear without the driver having to change his position. All the controlling parts are grouped in such a way as to render the driving of the vehicle very easy.

BRIDGEPORT, CONN., is considering an ordinance restricting the speed of motor-vehicles to seven miles an hour within a radius of one mile from the railroad station.

ACCORDING to the *Vélo*, the French Minister of Justice has decided that automobilists arrested for driving at an excessive speed shall in future be prosecuted in virtue of Article 475 and not Article 476, which means that they will be liable to a fine only and not imprisonment.

THE formation of the Compania de Transportes de Matagalpa is reported from Nicaragua to establish services of road trains in districts not provided with railways. The Government is reported to have given its support to the company's projects.

MESSRS. ERNEST HUTTON AND COMPANY, LTD., Ohm Electric Works, Northallerton, inform us that they have taken an order from Major Bower, Chief Constable of the North Riding of Yorkshire, for one of their new 4-h.p. voiturettes. The firm have also been appointed special agents to a well-known fire insurance company for the insurance of automobiles against fire, and they are now able to take these risks at 5s. per cent. for cars fitted with electrical ignition and 7s. 6d. per cent. for those fitted with tube ignition.

FURIOUS DRIVING CASES.

At the Chertsey Petty Sessions last week, Mr. Ernest Russell, of Brixton, was summoned for driving a light locomotive while drawing another at more than six miles an hour, at Weybridge, on July 1st; he was further summoned for not having the owner's name and address on the locomotive.—P.C. Bettison explained that he stopped the defendant for driving at a furious rate, but that subsequently Inspector Marks came up and told the defendant that he ought not to go more than six miles an hour when he had another vehicle attached to the motor-tricycle he was driving. There was another motor with the defendant, but the driver pushed on and escaped. There was a car attached to the tricycle, in which there were two ladies. The defendant was going at the rate of sixteen miles an hour.—The defendant said he had been many times through Chertsey and Weybridge, but had never been stopped before. He was also unaware that he ought to have his name and address on the locomotive.—The Chairman asked Inspector Marks if the other driver had been found.—The Inspector: No; the defendant withholds the name.—The Chairman told the defendant that it was a dangerous practice to drive a motor at such a rate, and he would be fined £5 for the first offence and £1 for the second.

On Saturday, Robert Wilson, cycle dealer, Bedford, was fined £10 and costs for furiously driving a motor-tricycle. It was stated that defendant was going between 25 and 30 miles an hour, and that from fright a horse bolted, the driver was thrown out, and a cart was overturned. The chairman of the Bedford Bench said they were determined to put a stop to the furious driving of motors.

At Gainsborough on Tuesday Mr. Herbert W. Bamber, manager of the Aegir Bicycle and Motor-Car Works, was fined 10s. and costs for driving a motor-car at a furious pace. It was stated that the car travelled at eighteen to twenty miles an hour.

DRIVING TO THE COMMON DANGER.

At Westminster Police Court last week, John Goody, servant to Mr. Edmunds, of Upper Tulse Hill, was, under the Police Act, summoned before Mr. Francis for unlawfully driving a motor-car at Pimlico to the common danger. Mr. Staples Firth defended. The police evidence was that the defendant, turning a corner at the rate of fourteen or fifteen miles an hour, proceeded on the wrong side of a refuge, and that to escape being knocked down seven or eight persons scattered in all directions. After a very long cross-examination as to facts which were in dispute, Mr. Firth contended that there was no actual evidence of common danger or injury. He quoted High Court cases to show that the danger must be actually existent, and argued that the mere supposititious ideas or mere opinions of policemen as to danger were insufficient. Mr. Francis: I should hold that the mere fact of going on the wrong side of the refuge was evidence of common danger. Mr. Firth said he should be very pleased to take a case on this point. He raised a further point decided by the High Court in "Stanley v. Farndale," that a policeman was not a passenger on a highway, and that to support a prosecution there must be the evidence of some bona fide aggrieved passenger. In the end Mr. Francis dismissed the summons on a technicality—one witness not being in accord with another as to the date of the alleged offence. His worship added that on the merits of the case he should have decided for the police, on the ground alone of going the wrong side of the refuge. He refused costs.

At the City Police Summons Court last week Mr. Gust. Mees, of Fulham Palace Road, answered a summons for driving a motor-car to the common danger in Newgate Street by St. Martin-le-Grand. Police-constable 262 said that the defendant came down Newgate Street towards the Post Office at a very sharp rate. He (witness) signalled and shouted to him to pull up. He very nearly knocked down two pedestrians, and but for the skilful driving of William Oman, a man in charge of a pony-cart, a serious accident would have ensued. Leopold Tolch, a friend of the defendant, said that as soon as the officer called to them to stop the defendant complied. There was no danger whatever. They were going at a speed of five miles an hour. Constable 262 behaved to them in anything but a civil and proper way. The Alderman, saying that the case was proved, inflicted a fine of 10s., and 4s. costs.

THE BRITISH MOTOR COMPANY.

At the confirmatory meeting of the British Motor Company, Ltd., held at the Hotel Cecil last week, Colonel Harris presided, and in his opening remarks mentioned that the meeting was held to confirm or reject the resolutions passed at the recent meeting of shareholders in respect of the reconstruction scheme which had been laid before them. He was pleased to be able to inform them that 75 per cent. of the shareholders in the original company had acquiesced in the new scheme, so that the reconstructed company, if the resolutions were confirmed, would enter upon a new life under good auspices. So far as the directors were concerned, every halfpenny of the capital raised under the reconstruction would be applied to the business of the company, for the furtherance of its interests. In answer to questions, the chairman said that every shareholder who had paid £3 for his original share would receive an additional share in the new company with 17s. 6d. paid; but this was really a gratuity, as it were, given to them by Mr. Lawson, who, of

course, was responsible for bringing out the original company. The board had nothing to do with this arrangement, as it was a matter which lay between Mr. Lawson and the shareholders. He moved the confirmation of the resolutions passed at the recent meeting. The motion having been seconded, was duly carried. Mr. Barker, of Chiswell House, and Mr. Osborne, secretary to the company, were appointed liquidators at a fee of one hundred guineas inclusive.

In closing the proceedings the chairman said he wished to thank the shareholders who had entrusted the board with their confidence. He thought he was safe in saying that few reconstruction schemes had been arrived at with such a large percentage of proxies, and this was a satisfactory proof to the board that the directors retained the confidence of the shareholders. His connection with the company ceased from that day, but he wished every success to the new company, and he sincerely believed that their most sanguine expectations would be realised. So far as he was able to judge, the negotiations with the Anglo-American Company would prove eminently satisfactory to this company; and the combination would enhance the value of the shares of this company to a very considerable extent.

A shareholder, in proposing a vote of thanks to the chairman, observed that Colonel Harris had proved himself to be not merely an ornamental chairman but a working chairman, and he deserved the best thanks of the meeting for the way in which he had pioneered the company. He moved that a vote of thanks be accorded to the chairman and the directors.

The motion was seconded and carried, and the chairman, in responding, remarked that he had not missed a single meeting of the board since the formation of the company, and he had all along—a large shareholder himself—regarded the interests of the general body of shareholders as identical with his own.

MOTOR-CARS IN COLLISION.

At Darlington County Court, last week, two actions were brought against Mr. W. Hall for damage caused by a motor-car. Thos. Beach, of the Fleece Hotel Stables, claimed £15 16s. 6d. for damage to a trap and horse, and hire of another horse while the injured animal was getting better, etc. A second action was brought in connection with the same collision by John Routh, who was driving the horse, for injuries to his little girl and himself, alleged to be due to the negligent driving of the motor-car by defendant. The circumstances were, as detailed by the plaintiff, that Routh was approaching Darlington at 10.30 on the evening of June 17th, and when in Freeman's Place he was run into by the car, which was travelling the same way and overtook him. It was alleged on the side of plaintiff that he was travelling on the left side of the road, and that he was about three feet from the channel, leaving plenty of room for defendant to pass. The trap was overturned and all its occupants thrown out, Routh, the driver, being knocked insensible for some time, and his little girl's arm injured. The horse also was knocked over and its knees, plaintiff's witnesses said, were cut, and the ankle swollen. Beach stated that defendant offered £10 afterwards to settle the damage to the horse and conveyance, but he refused it. Defendant, also, it was stated, said that Routh, who was unable to work for a week, should not suffer. Defendant and a number of witnesses for the defence asserted that the fault was due to Routh, the driver, pulling his horse to the right as defendant was passing on the motor. It was denied that defendant had offered £10 to settle the matter. His Honour, in giving judgment, said it was established that the whole of the road was open, and the motor-car had an opportunity of passing at a considerable distance off, even if the horse had swerved to the right. He thought defendant must have turned the wrong lever or lost his presence of mind and so have driven into the horse. He gave a verdict for Beach for the amount claimed. The other case, in which Routh claimed, was not heard, but ultimately Ald. Wilkes, who appeared for plaintiff, accepted £7 offered by Ald. Barron, who represented defendant, in settlement, costs to rule in the first case only.

On the evening of July 19th a motor-car driven by Mr. Henry Sharp, of 77, Masons Hill, Bromley, Kent, came into collision with another motor-car at Masons Hill. It appears that the other motor, whose occupants are unknown, ran into Mr. Sharp's vehicle. The impact caused Mr. Sharp to lose his hold upon the steering handle, and the machine ran on to the pavement and through the shopwindow of Mr. May's jewellery establishment at Masons Hill. A pane of plate glass about three feet square was broken, and a blind-rod caught Mr. Sharp on the bridge of the nose and broke it. The injured gentleman was taken to the Cottage Hospital, where his injuries were attended to by Dr. Chatterton, and he subsequently drove home in his own car. The unknown motorists made off as soon as the accident occurred, and nothing has since been heard of them. Such conduct can hardly be too severely condemned or punished if the culprits are discovered.

MR. ALBERT C. BOSTWICK, the well-known young American *chauffeur*, who came over to Europe with a Winton carriage at the time of the International Cup, has returned to New York with his carriage, and at the same time has taken back with him four French carriages and one tricycle, including the Panhard-Levassor car which he bought from M. de Knyff.

THE Motor-Car Journal.

LONDON, SATURDAY, AUGUST 11, 1900.

[No. 75.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

ALREADY the committee of the Automobile Club is preparing the programme of its winter operations, and evidently it is intended to pursue a very active policy. During the last week in October the quarterly 100-miles trial will take place, and also a dinner on the 31st October at the Trocadero to those who took part in the 1,000 Miles trial. At that event the presentation of prizes will be an interesting item of the proceedings. Then in the first week of November the trial of electrical vehicles will take place, and on the 14th of that month the annual dinner will be held at the Hotel Metropole. A suggestion that there should be a tour to the sea coast on Saturday, 10th November, until Monday, 12th November, has been approved by the Club Committee, and the Touring Committee has decided to recommend that in connection with the anniversary of the passing of the Light Locomotives on Highways Act there should be a tour from London to Southsea on the dates named. It is recommended that the tour should be open to all vehicles, whether they be owned by members of the Automobile Club or not, provided that no advertisement be affixed to them. It is also suggested that in order to discourage high speeds on the run, the Club should offer diplomas in respect of vehicles which may complete the journey, the average speed not to exceed approximately twelve miles an hour, and no stops to be made other than those imposed by traffic requirements and the compulsory stop for luncheon. The speed of the vehicles ascending Hindhead Hill will be taken and recorded on the diplomas referred to.

Autumn Tour.

BEFORE entering on the winter programme, of which the first events are given above, an autumn tour is in contemplation. This will commence on October 5th, and will end on the following Wednesday evening. This year it is intended to go into Wales, and it is probable that Monmouth will be the central feature of the trip. On the Monday Lord and Lady Llangattock will, through their son, the Hon. Charles S. Rolls, invite participants in the tour to luncheon at their Monmouthshire residence, The Hendre.

Kindly Thought.

ON the suggestion of Captain the Hon. Cecil Duncombe the committee of the Automobile Club are inviting members of that body to subscribe to a fund to be apportioned (in the name of the Club) between the cab drivers, the omnibus drivers, and the police benevolent societies respectively. This has been decided upon in view of the trouble and sometimes expense to which omnibus and cab drivers are put by their horses during the period of their becoming accustomed to automobiles.

It is also intended to be a token of recognition of the services of the police during the meets and tours of the Club.

Hotels for Motorists.

WE are glad to see that the Automobile Club is taking into consideration the question of hotels. This is an important matter to automobilists, who have not always been well treated by many hotel proprietors. The committee of the Club has prepared a form which members will do well to bring before the notice of hotel-keepers. The Club will appoint special hotels for the use of its members, the proprietors agreeing to store vehicles, supply water for washing, store petrol, keep lubricating oil, fix a hose-pipe, and be reasonable in their terms for such service, and also in charges for meals and beds. One clause deals with the charge for the temporary storage of vehicles while meals are being taken—an important consideration to motorists on tour. Something practical should result from the suggestion.

The Shah in Paris.

THE Shah and his doings have been the principal subject of conversation in Paris ever since Mouzaffer-ed-Dine arrived in France, and not the least interesting feature of his visit is the part that automobilism has played. It would appear that for some time past the Persian ruler has desired to acquire a self-propelled vehicle, but did not possess great confidence in the safety of petrol, and feared the possibility of explosion with steam. But upon the report of certain members of his suite, the Shah last week sent for M. Serpollet, who duly appeared at the Palace des Souverains, in the Avenue du Bois de Boulogne. The car he drove was one of 8 h.p., and after demonstrating his entire control over the vehicle, M. Serpollet had the honour of driving the Shah for a short distance in the vicinity of the Palace. The trip proved so agreeable that the monarch repeated the experience, and the following morning saw him again the passenger of M. Serpollet. General Nazare-Agha, the Persian Minister at Paris, Hakim-el-Molk, the Minister of the Court, and Mohandis-el-Mamalet, the Minister of Public Works, were also taken a lengthy drive in the Bois, during the course of which the speed of the vehicle was demonstrated to their entire satisfaction. The upshot of these experiences has been the purchase by the Shah of two cars, the second carriage being a large omnibus, so before many weeks have passed the good people of Teheran will see their monarch speeding gaily along on a self-propelled vehicle. But with the personal acquisition of cars the history of automobilism in connection with the Shah's visit to Paris by no means ends. On the 2nd instant, when he went to Versailles, the great majority of the Press representatives travelled out there by motor-car, as also did M. Alfred Picard, Commissaire Général de l'Exposition, and M. Delaunay-Belleville. When visiting Vincennes, too, the automobile was employed by various high functionaries; indeed, it is now quite a common sight to see Ministers and Government officials making use of the motor-car when on official business.

A Motor-Car Service in Mid Wales.

MID WALES has now been provided with a public service car through the enterprise of Mr. Tom Norton, Llandrindod Wells. On Thursday last week a trial trip of a new Daimler wagonette to carry eleven was made from Swansea *via* Llandilo and over the Sugar Loaf to Llanwrtyd. Being some 2,000 ft. above sea level the gradients were a severe test, but the car never flinched, and covered some eighty miles of difficult roads in a satisfactory manner. Amongst the party besides the owner, Mr. Tom Norton, were Mr. J. Williams, director of the Swansea Motor Company, and Mr. W. M. Morris, Pontypridd, the district agent for the Daimler Company.

Development in Ceylon.

CONSIDERABLE interest is being taken in Ceylon in the scheme of the newly formed "Ceylon Rapid Transit Company." This is a syndicate of local residents interested in the development of mechanical locomotion on ordinary roads, and the suggestion is that the Government should abolish the unsatisfactory horse-drawn mail coaches and send postal matters by automobile. An endeavour will be made to get the Government to allow a trial between Negombo and Colombo. This route, it is believed, will fully answer the purposes of the experimental stage. The cars would be put on the road and would daily convey the mails to Negombo, returning the same night, and thus effectually justify the title of the Rapid Transit Company. It has been estimated that the cost of running these cars would range between 35 and 40 cents a mile. If the scheme is brought to fruition the undertaking will open up the prospect of the employment of capital on a large scale, and it is to be hoped that no difficulties will be thrown in the way of the promoters in arriving at a correct opinion of the possibilities of the venture after a full and thorough test. Cars are already on their way out which will be utilised in the interesting experiments shortly. These are being obtained from the Lancashire Steam Motor Company, whose headquarters are at Leyland. Other contracts have been placed, according to a Ceylon journal, with Messrs. Coulthard and Company, of Preston, Lancashire; Messrs. Simpson and Bodman, of Manchester, Bailey's Limited, London, and the Thornycroft Seam Wagon Co., Limited.

For Passengers and Mails.

THE cars it is proposed to adopt are built to carry eight first-class and ten second passengers, as well as mails and luggage at the back. The "cab" for the driver and the machinery is in front, entirely separate and distinct from the rest of the conveyance, whilst special means have been adopted to prevent heat or smell being obnoxious to those travelling. It is intended to run these mail coaches at a speed of about eight miles an hour, and the plans and drawings of the cars exhibited at Colombo have aroused considerable interest. The roads are good and present no great difficulties, and it is clear that, given facilities, a very much larger number of people would travel by coach than do at present. The company, of course, accept all risk on their account, and only ask that the expense they are being put to in providing these cars and the greater comfort and convenience for the travelling public which they provide, as well as the greater speed, should be acknowledged by a substantial subsidy from the Government. Sir West Ridgeway is distinctly a progressive Governor, and confidence is felt that his support to the scheme will be readily secured. We may add that the manager of the company is Mr. W. H. Beamish, who thus attains the distinction of being the first to utilise automobiles for public service in the tropics.

Royal Motor Artillery.

A SUGGESTION made in these columns at the time of the Tugela River reverse and the loss of guns by Colonel Long is revived by Mr. W. S. Shaw in the *Pall Mall Gazette*, who writes as follows:—"It is a lamentable fact that we follow where we ought to lead in military matters. The average price

paid for battery horses is, I believe, £50. This means, leaving aside officers' chargers and the horses of sergeant-majors, trumpeters, etc., that a battery of six guns costs nearly £2,000 for horseflesh. An armour-plated (sufficient to protect from rifle fire) high-speed motor-engine capable of drawing any field gun could be built for, probably, under £200, but, putting the cost at the same as the gun-team of six horses, we will say £300. Now, where are we? There may certainly be places where horses can go that motor-engines cannot, and for that reason we shall want horse artillery as well as motor artillery; but, in many places, motor artillery could "gallop" into action at thirty or even forty miles an hour, which would enable them to almost ignore rifle fire. 'A motor-engine wants an engineer,' says some one. Yes, and a horse wants fodder, also shoeing. To shoe a horse you want a farrier, and the farrier wants a forge. To say nothing of the veterinary surgeon."

A General on a Motor-Car.

WE are not without hope that something will be done in the matter, and that the constant reiteration of the advice to the military authorities to try experiments with motor traction may, at length, lead to some real advance. Major-General Maurice, whose warm espousal of military cycling is creditable to his enterprise, supervised the operations in connection with the experimental cyclist manoeuvres last week end from a De Dion quadricycle supplied by the De Dion-Bouton British and Colonial Syndicate, Ltd.—the first time a British general thus committed himself to such a vehicle when on service. Remembering the story of the oak and the acorn, we look forward to a real military motor field-day in the next century, but whether late or early in the era depends on the persistency of the advocates of motors for military purposes.

The Approval of "The Times."

COMMENTING on the manoeuvres, supervised by Major-General Maurice, *The Times* says:—"During the exercise the value of motors in operations over large areas was shown. When a fight commences the quadruped is undoubtedly the proper conveyance for the commanders, but otherwise the motor is preferable to either horse or cycle, because it enables those whom it conveys to arrive at their destinations as fresh as when they started. It must be owned that the spectacle of the general in a sort of bath-chair with a driver behind him, of the second staff officer in a sort of invalid's chair with a driver in front of him, and of the chief staff officer on the box seat of a wagonette, was not in itself imposing; yet, when, on return from Sunday afternoon's work with the troops, the bath-chair carried off the general to billets sixteen miles away and brought him back to headquarters in an extraordinarily short space of time, military dignity hung its head before real utilitarianism."

Mechanical Traction in War.

WHILE writing on this topic we would make reference to the work on "Mechanical Traction in War" which Messrs. Sampson Low, Marston and Co. have published. This has been translated by Mr. R. B. Marston from the German of Lieut.-Colonel Otfried Layriz, and deals both historically and technically with the subject. The first chapters are devoted to a summary of the well-known early history of mechanical traction, and these are followed by an explanation of the Daimler system and a review of some of the more interesting experiments that have been made with light automobiles. Thence to the end of the volume the automobile as traction engine forms the staple matter, although one chapter is devoted to the Serpollet steam car, which can be used as an automobile and also for traction. The references to the use of traction engines in the South African campaign are necessarily incomplete, but enough evidence has reached us to show how useful they have been. Mr. Marston has added a useful appendix, referring to the 1,000-Mile Trial, and the book fills a vacant niche in automobile

literature. At the present time, when reorganisation of some military departments and the general examination of our ideas on military matters is much talked of, no book could have been more opportune. We hope it will be read by every officer and its lessons recognised by every civilian.

**Motor-cars
for
Australia.**

IN our correspondence columns appears a letter from an Australian reader who is evidently anxious to assist in the development of the automobile movement in the colonies. We would suggest that manufacturers might send copies of their catalogues to the Rev. Garvin Tucker, who is well known to many members of the Queensland Government.

**The Joel Electrical
Voiturette.**

ON page 391 we are able to give an illustration of the Joel electrical voiturette which ran so successfully to Brighton a few days ago. As an account of the trip, together with some particulars of the vehicle, was given in our last issue, it need only be mentioned that it has been constructed under the patents owned by the National Motor-Carriage Syndicate, Limited. The voiturette is equipped with two 2 h.p. Joel electric motors, fixed on a detachable spring frame, driving the two back wheels of the carriage separately by chain gear. The current is supplied by thirty-two Rosenthal storage batteries, made up in two sets of sixteen cells, with an output of 140 ampere-hours. The total weight of the carriage is under 12 cwt.; of this 7½ cwt. is battery, motors 2 cwt., and the carriage itself only 2½ cwt. The wheels are shod with pneumatic tires, the back wheels are 2ft. 9in. diameter, and the front wheels 2ft. 6in. diameter. The controller is very simple in construction and action. The system of electrical changes is such that when the voiturette is ascending hills the motors work at their highest efficiency and at normal speed; they are geared down to run the car up hill at six miles an hour, whilst on the level the speed ranges from eight to twelve miles, or faster if desired. There are also available two slow speeds forward of three and four and a-half miles, and a slow speed backward of three miles per hour.

**A Motor Car
for 7s. 6d.**

IN obliging others Mr. Martin Rucker has again come to grief—or, rather, his car has gone the way of destruction. On Monday he was taking a run from Harrogate to Leeds, when he put the brakes hard on to accommodate the driver of two restive horses. The wheels skidded, and the vehicle rolled into the ditch. Then the petrol caught fire, and in a very few minutes a handsome Daimler, which cost over £600, was reduced to twisted ironwork and charcoal. It is stated that immediately the flames showed themselves, Mr. Rucker, who could foresee the end, asked for a bid for the machine as it stood from a party of trippers from Leeds. A general dealer offered 7s. 6d. The offer was accepted, and Mr. Rucker returned with three half-crowns instead of the powerful machine in which he had set out. The general dealer may be said to have got ample value for his money, for the engine could not be greatly impaired by the fire, and will no doubt eventually be incorporated in some other car.

A Blaze at Lincoln.

AT Lincoln, last week, a motor-car plying for hire in the streets took fire. The car was running at about eight or ten miles an hour, when flames suddenly burst out in front, the oil tank having become ignited. A lady sitting near the front of the car rushed to the back with the object of jumping out, but was prevented doing so by a gentleman passenger. The flames rose to a height of several feet, and played round the driver, who succeeded in pulling up the car. His eyebrows were singed. A bucket of water extinguished the blaze, and the mechanism of the car was not injured. The front seat, the

steering wheel, and other parts of the car were damaged, but no one was injured. Beyond furnishing the local papers with a paragraph no harm was done.

**Commercial
Travellers
and
Motor-Tricycles.**

A COMMERCIAL traveller, of Cardiff, going through South Wales every day, with a fair amount of luggage, writes that he is about to adopt a motor-tricycle for his business journeys. We commend him for his thought, and can assure him that the use of motor-tricycles by business men is becoming more and more common, the saving of time being recognised as a great advantage. Our correspondent adds that he would like a hood over his tricycle to protect himself during wet weather. Having been caught on Mitcham Common in Monday's gale, we can quite sympathise with his wish, but are afraid great gusts of wind would find pleasure in playing about that hood. Anyhow, he can but try.

AN ORIENT EXPRESS CAR NEAR ST. ALBANS.

**A Scottish
Trip.**

A MOTOR-CAR passed through Hawick the other day on its way from Jedburgh to Dumfries, via Langholm, Gretna, and Annan, a distance of eighty miles, the time taken to accomplish the journey being five and a quarter hours. The return journey was made two days later, when the car again passed through the town, its attractive appearance being commented on by several onlookers. Mr. Love, of Kirkcaldy, Scottish agent for the Motor Manufacturing Company, the driver of the car, was accompanied by Mr. Inglis, jun., Jedburgh. In adding a few technical points to his account of the foregoing event, a local reporter says:—"The motor power was engendered by petroleum, the engine being six-horse, and the car capable of carrying five persons."

**Reading
Automobile Club.**

THE Reading Automobile Club is getting along, as the following from the *Berkshire Chronicle* will inform our readers:—"At the invitation of Sir Charles and Mr. Arthur Russell, the first meet of the club took place at Swallowfield Park. The weather was perfect, and members left the club premises in Minster Street shortly after four o'clock, arriving at Swallowfield shortly before five. Many varieties of motor-cars were represented, the petrol car, the steam car, and motor quadricycles, tricycles, and bicycles. The members of the club were met at the Park gates by Sir Charles and Mr. Russell, both

of them being vice-presidents, and after a very welcome tea in one of the beautiful rooms of the hall, where Miss Russell most hospitably performed the arduous duties of hostess, photographs of the cars were taken in group. The hostess and visitors in the house were then driven round the Park in the various motor-cars, and further animation was given to the scene by the fact that a school treat was proceeding in the grounds at the same time, so that practically the whole of the village witnessed the meet, and most thoroughly appreciated the event. Notwithstanding the fact that a great many people and children were present, not a single mishap of any kind occurred. The members returned home about 7.30 p.m., being escorted part of the way by their hosts on their own car. The event proved a brilliant success, which was in great measure due to the welcome and the hospitality offered, and to the beautiful surroundings. Arrangements are being made for a motor gymkhana to be held in the autumn, which will still further popularise the use of motor-cars. The club is in a very active and flourishing condition, ten new members having been elected last week, five of them being medical men. Membership does not necessarily involve ownership, but those who are awaiting 'perfection' have the opportunity of occupying any vacant seats that may be available, and they can thus revolve the question in a practical manner in their own minds."

Touring through the Lake District.

THE celebrated novelist, Ian Maclaren (Rev. Dr. Watson), has ventured on another voyage of discovery, which will in all probability "be productive of much good," as the preachers say. The other morning, at the early hour of five, the Rev. Dr. Watson, accompanied by Professor Hele-Shaw, of Liverpool University College, set out from the house of the former, Croxteth Road, Liverpool, on a motor-car belonging to the professor. They were accompanied by an engineer, and their ultimate destination is Scotland. They were in high spirits, and were in hopes of breakfasting at Preston, whence they make for Windermere, and in easy stages go to Stirling. This is the novelist's first experience of motor-car riding, but under the skilful guidance of Professor Hele-Shaw there is no doubt the trip will be a delightful and enjoyable one.

Necessity of Knowledge.

AND this leads us to another point. In order to thoroughly enjoy motoring the novice must be accompanied by a practical person. Otherwise the delights of the journey may fade as the chances of progress diminish. There are people who have an idea that the propulsion of a motor-car is like working a musical-box or winding a keyless watch. At present the management of a motor-car has not been reduced to kodak-like simplicity, and Ian Maclaren shows much worldly wisdom in the choice of his associates on this—his first—motor-car trip.

Motoring and Sport.

THE connection between sport and automobilism is becoming closer every season. Mr. Mackay, who has taken Dunachton from The Mackintosh of Mackintosh, has also taken Ben Alder, one of the most ancient deer forests in Scotland, which was ratified as such by an Act of the Scottish Parliament in 1685. Mr. Mackay is going to use a motor-car as communication between the two places, which are twenty-five miles apart. In such circumstances the automobile ought to demonstrate its value with ease.

Invading America.

MR. W. K. VANDERBILT, JR.'S, 30 h.p. Daimler racing-car, the first of its kind ever taken to America will have some worthy rivals before long. The purchase by Mr. Albert C. Bostwick of René de Knyff's Panhard racer, which carried the celebrated Frenchman

year, was recorded in these columns some time ago. Now we are able to announce, states the *Horseless Age*, that four other machines will appear in America this autumn. Mr. David Wolfe Bishop, Jr., will take with him from Europe a 12 h.p. Panhard; Mr. Clarence G. Dinsmore a Mors vehicle, of power not stated; and Mr. J. Howard Johnson two Mors machines, one of them being of 40 h.p., and built to carry eight people.

Railway Companies and Motor-Vehicles.

AT length it would seem that the railway companies are inclined to recognise the advantages of the motor-vehicle in conveying passengers and luggage, and generally acting as feeders to their regular lines. At least one is conducting an experiment, and should that succeed the others may be trusted to follow suit. The Midland Railway Company is testing a steam lorry from Mann's Patent Steam Cart and Wagon Company, Limited, of Leeds, in connection with their town cartage at Masborough, and doubtless the managers of other lines will await the result with interest.

Seeing Berlin.

A MOTOR-CAR drive was recently organised by the proprietors of one of the leading hotels in Berlin for the benefit of its many foreign visitors. Arrangements were made with the Berlin Motor-Wagen Gesellschaft to supply a number of vehicles with drivers. No less than thirteen cars were altogether required, these consisting of both petrol and electrically-driven vehicles, ranging in size from a victoria up to a large motor-omnibus. Upwards of seventy persons joined the party, who visited the leading places of interest in the German capital and the Mausoleum in Charlottenburg. The drive occupied three hours and a half, and according to all accounts was much enjoyed.

Why Not in London?

NOW that such experiments have been made in Paris and Berlin the hope may be again expressed that some of the enterprising London hotel managers will recognise the profitable character of the idea, and put it into practice. Motor-vehicles could certainly be reliably employed to enable visitors to see the sights of London in the minimum of time, and, we might add, at a reasonable expense.

A Pleasant Week's Tour.

MR. STOCKDALE, of Lancaster, had an enjoyable run a few days ago on his Marshall car, carrying four passengers. Starting from Lancaster on the 26th ult., he travelled that day to Appleby, a distance of 74 miles; on the second day he went to Moffat (66 miles), and then got to Edinburgh, 52 miles further. He stayed in the Scottish capital on Sunday and Monday, and on the following Tuesday travelled to Alnwick (88 miles). On the Wednesday he went to Ripon (100 miles), and on the following day returned home. This is a capital week's itinerary for other automobilists in that district.

Photographic Competition.

IT will be remembered that Mr. Edmunds offered prizes for the best sets of photographs in connection with the 1,000 Mile Trial. In response to his offer half-a-dozen sets were submitted, and the awards have just been made. The first prize of £5 has been won by Mr. E. M. Iliffe, of Coventry, the second of £2 by Mr. Argent Archer, of Kensington, and the third of £1 by Dr. Cecil Sharpe, of Darley Dale, Derbyshire. In arriving at this decision the committee considered not only the technical excellence of the photographs, but also the general interest of the subjects selected.

AUTOMOBILE TOURING IN THURINGIA.

THE Thuringian city of Eisenach, the home of the Mittel-deutscher (Central German) Automobile Club, has the good fortune to have a rarely beautiful and picturesque environment, offering many delightful tours. The club's first excursion of the season was to the famous old castle of the Wartburg, near at hand. The Wartburg was never a ruin, having by good fortune escaped the devastations of the thirty-years' war, and other periods of strife that destroyed the greater number of the evidences of ancient days in the land. It is the best preserved and the most beautiful old castle in Germany—a perfect example of feudal architecture, rich in history, legend, and tradition, the

are the sides that the attempt to ascend it by automobile looks to the stranger an impossible undertaking. But the tortuous road rises by easy grades, and the excursionists found it a really light task. On arriving the party was hospitably taken in charge by the captain of the Castle, Major von Cranach, a descendant of the world-famous painter of that name and an enthusiastic automobilist. Familiar as the Wartburg may be to a visitor, the enchanting prospects which it commands, beheld from a foreground so romantically picturesque, never pall upon one, and the automobile visitors from the neighbouring city enjoyed the occasion most thoroughly. But what would Luther and the Minnesingers have said to the procession of automobiles invading the historic precincts? Would it not have seemed like a segment of the Apocalypse, more wonderful and dreadful than the seven-

THE JOEL ELECTRICAL VOITURETTE. (See page 389.)

centre for the assembling of the Minnesingers in their contests of song, and consequently the scene of Wagner's "Tannhäuser," and also the residence of Martin Luther during an important period of his life. It was here that Luther worked on his translation of the Bible that created the German language as a literary tongue as well as revolutionised the religious world. The place where Luther flung the devil out of his inkstand against the wall while engaged in this sacred duty is still shown in the "Lutherzimmer," or Luther-chamber, but the huge blot of ink made by his Satanic Majesty on coming in violent contact with the wall has to be renewed occasionally to make good the depredations of tourists. The summit of the hill occupied by the castle is nearly 700 feet above the level of the valley, and so precipitous

headed beasts and other monsters of the apostle's vision?—*The Automobile Magazine.*

THE next 100-mile trial of motor-vehicles, under the auspices of the Automobile Club, will be held on Thursday, November 1st. September 3rd is the last date for entries.

THE City Council of Urbana, O., is discussing an ordinance limiting the speed of motor-vehicles in that town to four miles an hour, and requiring that all such vehicles shall be equipped with a bell or gong, and the same shall be sounded when within fifty feet of a crossing, and kept sounding until after the crossing is passed. The ordinance also requires lamps to be placed on the front end of the machine.

PARIS EXHIBITION NOTES.

(FROM OUR OWN CORRESPONDENT.)

(Continued from page 359.)

I STRONGLY recommend every visitor to the automobile section at Champ de Mars to carefully inspect the exhibits of the Société Industrielle des Téléphones, which are to be found just behind the stand of the Compagnie Internationale de Transports Automobiles. Although but a recent recruit to the ranks of French motor constructors, this company is famed all the world over for the excellency and diversity of its electrical productions and it is evident from the articles exhibited

FIG. 1.—PLAN OF AUDIBERT-LAVIROTTE CAR.

that the new class of work will be fully up to the standard of that constructed for the older branches of the company's business. And then, too, in addition to the beauty of workmanship, the motors shown are of special interest by reason of their being the outcome of the fertile brain of M. Ader, whose many wonderful inventions in connection with the telephone, etc., are so widely known and so extensively employed. At the present moment the motor is constructed in two types, viz., 6 and 3 h.p., the sole difference in design being that the former is water-cooled, whereas the latter is air-cooled. Working upon the "Otto" cycle, the motor has two cylinders set at an angle of 90 degs. The piston-rods are attached to the same point of a short shaft, which carries a couple of flywheels, the whole encased in an aluminium gear box. The explosions are produced by the ordinary system of electric ignition. The system of water-cooling adopted presents some novel features. The water which is contained in the cylinder jackets is, under the action of the heat, changed into steam, and as such passes into a condenser, which is a copper tank cooled by flanges fixed to the motor shaft. In the form of water it falls then into a small reservoir, then passes into another similar receptacle, and finally mounts again by means of pulsometers into the cylinder water-jackets. The pulsometers are indiarubber membranes, to which the differences of pressure in the motor base chamber give an oscillating movement, and thereby cause the water to ascend. The carburettor is built up of aluminium, and is in shape a parallelopiped. In this box there are placed about twenty large rectangular meshes, of which the lower part is bathed in petrol, and which are separated by intervals of some millimètres. The petrol mounts by capillarity in these meshes and impregnates their surface, which is then scoured by the inrush of air. An inspection of the frame of the car at once reveals that it is built up of two parts, the one rectangular, the other triangular. The front axle forms the base of the triangle of which the apex rests on the near side of the rectangular portion of the frame. This latter is sustained by the back axles. Under normal conditions the planes of these two parts blend, but they can incline, the one upon the other, so giving to the car great suppleness, and assuring easy travelling over the most irregular of roads. The motor itself is carried in the fore-part of the frame, while the carburettor, petrol tank, accumulators, and induction coils are all stowed away beneath the driver's seat. An induction coil for each cylinder is used. The motor drives a shaft which carries at its extremity a kind of friction clutch and also a

small pulley, the latter being fitted on its rim with a series of springs, by the intermediary of which the propulsive effort is transmitted to the wheels. With such an arrangement any sudden shock which the car may receive while travelling is only communicated to the cylinders after the springs have deadened the greater part of the blow. It is on this kind of little pulley that the flanges for cooling the condenser are fitted. The friction clutch is provided with a graduated leather face, so arranged that when at all damaged the material can be pressed backwards and the clutch continued to be used for a long time without further repairs. The female end of the cone commands the shaft carrying the speed change gear. There are three forward speeds and a separate reverse motion. The transmission of the propulsive effort is finally completed by means of a differential and ordinary driving chains. The pipe connecting the motor to the exhaust box passes through another and larger tube, so heating the air which is drawn in through the latter to the carburettor. The car is fitted with two brakes. The first, which is a hand-brake, acts upon the rear wheels, while the second, operated by a pedal, is connected to the differential. The application of either produces exactly the same effects: (1) To disconnect the friction clutch; (2) to cut off all but sufficient explosive mixture to keep the motor running, thus minimising vibration and economising petrol; (3) to apply one or other of the brakes. On mounting the car one is at once struck with the easy running of the motor, a result attributable to the perfect balancing of the engine and the combination of the two cylinders with the double flywheel. The exhaust, too, is remarkable for its exceptional freedom from smell, for the carburettor employed furnishes a very homogeneous explosive mixture. The car itself will be found to be of light yet strong construction, and its double frame gives remarkable suppleness. The driver has a great variety of means for the regulation of the force of the motor and the pace of the car, such as the change of speeds, the partial disconnection of the motor by the medium of the friction clutch, the advance of the ignition, the cutting off of the explosive mixture, and the regulation of that mixture. There should be undoubtedly a great

FIG. 2.—DIAGRAM OF STEERING WHEEL AND VARIABLE SPEED CONTROL GEAR—AUDIBERT-LAVIROTTE CAR.

future for this car. Indeed, I understand that already the Société des Téléphones are doing excellent business and booking many orders.

A small voiturette on exhibition is that constructed by M. Léon Buat of Senlis (Oise). This is a four-seated car fitted with a 3½ h.p. water-cooled De Dion motor. Three speeds of 8, 18, and 30 kilomètres per hour are used, and the driving is by means of a friction clutch. The frame is built up of cold drawn steel tubes, and the front part is mounted on a pivot. The consumption of petrol over ordinary routes is 10 litres to the 100 kilomètres. No chains are employed, the transmission being

direct by means of a series of cogwheels. Wheel steering is employed, and the usual hand and pedal brakes are fitted. The price of this little vehicle is £160.

Another provincial firm is MM. Audibert and Lavirotte, of Lyons, who exhibit one of their large cars, a plan of which is given in Fig. 1. The motor built by this firm is horizontal, two cylinders being employed for engines developing up to 16 h.p. and four cylinders for the larger types. Either electric or tube ignition can be fitted, and as the admission of gas to the cylinder can be accurately regulated the makers claim a minimum of vibration for their engine when running light. Inclined wheel steering is employed, and just below this wheel is found a second wheel by means of which the speed changes are effected (see Fig. 2). As this wheel can be manipulated either way the change from the highest to the lowest speed, for example, can be effected without passing the intermediate speeds. The frame is double and built of steel tubes. The carburettor is of a special patented pattern, and the water circulation is effected by means of a thermo-syphon, thus dispensing with a pump. The brake pulley on the differential shaft is hollowed out and carries a quantity of water, which, circulated continually by centrifugal force, ensures the efficient cooling of the brake. The other brakes used are the usual ones acting on the sprocket wheels.

Ranged just beside the charming pavilion which serves as the rendezvous for all motor men wishing to meet in the class 30, is the stand of MM. Renault Frères, upon which are to be seen two remarkably pretty little voiturettes. First of all there is a dainty coupé, driven from the interior, and then a smart two-seated car with a "spider" seat behind for a servant. Efficient as it undoubtedly is, and smart as it certainly looks, I do not like the manner of fixing the water coolers upon the motor casing, and the reason is obvious. Should anything go wrong and it is found necessary to examine the motor, the casing cannot be removed without disconnecting the radiator, and this is always a loss of time, besides being a troublesome job with pipes unpleasantly hot. MM. Renault also expose the first and second medals for the voiturette classes in the Paris-Trouville, Paris-Ostend, and Paris-Rambouillet races, and they will doubtless soon add the trophy so honourably won in the Paris-Toulouse-Paris of a fortnight ago.

Upon the other side of the pavilion there is to be seen the single car exhibited by M. Henriad. This is a 25 h.p. vehicle of this year's type, and, according to its label, the car accomplished no fewer than 3,800 kilomètres during the month of June last. The route followed for this extensive run was from Paris by way of Belfort, Berne, Genève, Bierme, Bâle, Strasburg, etc., returning to the capital after an absence of some days. The car is said to run up to 80 kilomètres per hour, and to work equally well on alcohol, petrol, or acetylene. The motor is carried in front under a long Mors-like bonnet; inclined wheel steering and Michelin tires are fitted.

Another conspicuous exhibit is that of Messrs. Albert Darracq and Co., of Suresnes (Seine), who are the constructors of the new Léon Bollée voiturette, in addition to the justly celebrated Perfecta motor-cycles. The former class of automobile is represented on M. Darracq's stand by three complete vehicles and a "chassis," or motor and frame, the latter exhibit enabling the seeker after knowledge to obtain an excellent insight into the principle of the Bollée system. For my own part I am no admirer of this voiturette, for I consider it to be as complicated in construction as it is unattractive in appearance. A couple of nicely-finished quadricycles, both carrying De Dion motors, are further shown, and the remaining space is occupied by two racing tricycles. Of these, the one is fitted with a 5 h.p. Soncin engine, and the other with a Buchet motor developing 3½ h.p. The lines of these two machines give one a capital idea as to the trend of constructors' opinion on the requirements of racing cycles; and the lowness of the frame, the width between the rear wheels, and the length of the wheel base will at once be remarked. M. Darracq has had a very extended experience with cycles constructed specially for speed purposes, and the successes achieved by his machine in all the big races of the year speak volumes for the excellency of the design employed and the soundness of the materials and workmanship.

La Compagnie Internationale de Transports Automobiles is the society which constructs electric vehicles in France under the patents of Monsieur Jenatzy, and its exhibit consists of three electromobiles. There is first of all a large electric delivery van of the type employed by the "Louvre" and similar establishments, and which are to be seen daily upon the streets of Paris. Then there is a very stylish phaeton with all seats facing forward, the body of which comes from M. Boulogne's workshops. The third car is of Mulbacher build, and is a really handsome "victoria." This year "La Jamais Contente," which attracted so much attention to this company's stand in 1899, is conspicuous by her absence. This is to be regretted, for there are so many thousands of strangers now in Paris who take an interest in automobilism that the fastest car in the world would have proved an enormous attraction.

(To be continued.)

THE "PALACE" DOG-CART.

THE accompanying illustration shows the little dog-cart which we recently inspected at Messrs. Friswell's dépôt on Holborn Viaduct, E.C., and to which we briefly referred in our issue of the 28th ult. The little car, which is arranged to seat two persons sitting *dos-à-dos*, is propelled by a 2¼ h.p. air-

cooled Aster motor, located under a bonnet in the fore part of a tubular frame. Two speeds are available, a single belt conveying the power to a short countershaft behind the rear axle, to which in turn it is transmitted by spur wheels. The steering is controlled by an inclined hand wheel, while the cycle-type wheels are shod with pneumatic tires. The miniature vehicle is said to run extremely well.

THE Rex Patents Limited, of Clapham, S.W., have recently put on the market a new set of eye protectors for automobilists. They are fitted with flexible curled sides, fine gauze shields, and solid nickel frames. The lenses are referred to as being scientifically toned so as to prevent chill to the eyes in cold weather, and to form a cooling for them in hot weather.

CADETS from the U.S. North Western Military Academy started on July 19th from Highland Park on a trip to Washington with the automobile rapid-fire gun, built by the Duryea Company about a year ago, and illustrated in our issue of October 6th last. The party intended to go by way of Toledo, Cleveland, Buffalo, and New York, and to camp out at night along the route. The nominal object of the trip was to carry a message from General Wheeler to General Miles.

CORRESPONDENCE.

IRISH ROADS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Reading in your issue of the 4th inst. the interesting account of the Irish tour in which I took part, it struck me that your readers might be led to suppose that the roads traversed were uniformly bad. Such was not the case. Of the 700 miles covered I would class about 20 miles in the Co. Cork as absolutely vile. Probably we encountered 20 miles of bad road elsewhere, and of the rest the greater portion was good and some excellent, and as good as any road I have come across in England. In Ireland we have "samples" of all sorts of roads, and in some cases the dividing line can be told with absolute precision by the jolt with which the traveller crosses from one county into another. Perfect touring, either for motor-car or cycle, can be enjoyed in this country; but it would be essential that a proper route should be sketched out, for if one were to tour through the country at random one might have a very bad time of it indeed as regards roads.

Dublin,
August 5th, 1900.

Yours truly,
R. J. MECREDY.

QUESTIONS RE MOTOR-CYCLES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I beg to ask if you or any of your readers could give me a little advice in regard to a little matter concerning a Beeston "quad." The exhaust valve spindle is lifted for starting by the brake lever, which by means of an inclined fork raises the exhaust valve off its seating and allows the compression to pass into silencer, thereby considerably easing the work of starting by the pedals. I find that it does not lift the valve sufficiently, and with the brake and this valve lifter being worked from one lever the tendency is for the brake to be applied before you can get sufficient lift to ease the starting. I think that if something independent of the brake lever could be applied it would be much simpler. I have heard that something has already been applied to this purpose by the makers of a special brake—Bowden's, I believe—and would be glad of further particulars.

I notice in a recent issue a case at Chertsey Petty Sessions, which interests me. Is it right that, if you have a tricycle drawing a trailer, you must have your name and address displayed and not go at more than six miles per hour? The case reads so to me. I have the same arrangement as above, but have never heard of the stipulations mentioned in the Chertsey case.

Yours truly,
T. SMITH, JUN.

Stockport, August 4th, 1900.

CHARGING ACCUMULATORS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Being a long way from any source of electricity I have been trying to charge a pair of Benz accumulators from three primary chromic and sulphuric acid cells. The makers told me the three cells connected in series would charge a pair of 2-volt accumulators, also connected in series, in about five hours. The pair of accumulators when new showed fully 5 volts on the meter, and they now show a shade over 4 volts. The three primaries, when freshly made up, showed about 5½ volts, but after being connected with the accumulators for about three hours their combined E.M.F. had dropped to 3 volts, and the accumulators showed exactly the same E.M.F. as before, viz., a shade over 4 volts. I then re-charged the primaries with fresh chromic and sulphuric acids, after which they again showed 5½ volts. I again connected them with the accumulators, and after about three hours found exactly the same condition of things as before, viz., the E.M.F. of the primaries had dropped to three volts, and the E.M.F. of the accumulators was still a shade over 4 volts, nor did the accumulators show the slightest sign of bubbling.

Will some practical electrician among your readers be good

enough to answer this letter, saying why the E.M.F. of the accumulators would not increase to the original voltage; also if it is safe to go on using the pair of accumulators in their present condition; if so, when must I stop using them, i.e., at what voltage? Any hints as to the charging and care of accumulators would, I am sure, be as useful to a large section of your readers as they would be to me.

Yours truly,

FRANCIS S. TIDCOMBE.

Bognor, Sussex, August 6th, 1900.

PNEUMATIC TIRES AND PUNCTURES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In reply to W. Vanderbyl's letter published in your last issue, he would most probably find the use of leather belting placed between the inner tube and outer cover of a pneumatic satisfactory as regards the prevention of punctures; but I should imagine the expense of having such tires constructed would be prohibitive, especially for cars of any appreciable weight, such as a Mors. The difference in weight between such a tire and an ordinary pneumatic would obviously be considerable, and a very perceptible detraction from the speed of the car would result.

I should recommend Mr. Vanderbyl to go in for Collier twin tires, which, briefly, consist of a thick solid rubber strip—secured next to the tread of the outer cover—on the inside of the canvas. Between this and the rim the air tube is situated, so that the whole tire is a combination of the solid and pneumatic varieties. They are made in all sizes, and are specially designed to prevent puncture, and spreading on the ground when in motion.

Yours truly,

W. G. BELL.

7, Loudoun Road, St. John's Wood, N.W.

August 7th, 1900.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—With reference to Mr. Vanderbyl's letter in your issue of last week as to the employment of leather belting between the air chamber and outer cover of pneumatic tires, in this connection it may be of interest to record that a piece of good, stout, leather, 9in. or 10in. long, placed in this position, in order to protect a weak part of a ninety millimetre tire, was found, after thirty miles of travelling, to have quite perished, in consequence of the heat when running—the leather breaking up into small pieces as it was taken out.

G. H. A.

Beaulieu, August 7th, 1900.

MOTOR-CARS FOR AUSTRALIA.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I am deeply interested in motor-cars, and desire any information as to price and capacity.

Tambourine Mountain is about 2,000 feet above sea level. I use a four-wheel dog-cart; two horses draw it up the mountain. There is a grand opening in this colony for a good car. One of our Brisbane merchants would give up his horses at once if a suitable motor-wagon were available for delivery. What is wanted is a very light machine, strong enough to carry one man and light samples for the back country.

What I want is a very light but strong carriage to seat four persons, with power enough to get up the mountain with ease, with powerful brake.

Yours truly,

REV. GARVIN TUCKER.

Yunlong, Tambourine Mountain, Brisbane,
Queensland, June 24th, 1900.

THE grand London pageant in aid of the War Funds will take place on the 20th prox. Mr. J. Mason, the Green Room, Hotel Cecil, Strand, W.C., is acting as honorary secretary.

A MACHINE AND ITS LESSON.

IN a recent issue of *La Locomotion Automobile* Gaston Sencier draws a moral from the design of the racing machine built by the Nesseldorfer Wagenbau-Fabriks-Gesellschaft, which was illustrated in the *Motor-Car Journal* for June 16 last. The builders of this machine, in describing it, laid stress on the fact that they had discarded all endeavour to imitate the form of a carriage, and, frankly recognising the essentially mechanical character of their production, had worked with the single object of adapting it as perfectly as possible to the end in view. "They are perhaps," says the writer above mentioned, "the first in our industry to claim the merit of understanding that an automobile is not a carriage, that there is a total dissimilarity between the two, and that the former has no more excuse for imitating a horse vehicle than there is for a locomotive being built to resemble a horse or a railway car like the old diligences of a bygone age.

"I know very well," M. Sencier continues, "that in saying so I run foul of preconceived ideas. But let those who profess these retrograde views give me one serious argument in their behalf, and I will listen to them. They have no argument at all, but the single one of public prejudice and accepted custom. It follows that the Austrian builders argue like men of good sense. They put before themselves a programme. We desire, say they, a vehicle carrying so many men, able to cover so many kilomètres without replenishment of petrol and water, and able to attain without danger a mean speed of so many kilomètres an hour. That is the whole matter. It is a mechanical problem to be solved. They have attacked it, and now present a first approximate solution. It is for that I congratulate them. The automobile industry has up to the present followed the common law of all new industries; it has been the slave of many prejudices and no less errors. It is by no means singular in this. Look at the old prints of the first railway trains built in England and France. The cars are almost copies of diligences, and the spirit of imitation extends even to the placing of a conductor on a special seat in each car. To-day the railway car is approaching its final form as seen in the modern express trains. *Au diable la diligence!* The cars are no longer made to satisfy the demands of a pretended æstheticism in imitating a bygone style. They have, therefore, found their true excellence of form. As to the locomotives, no one attempts to make them pretty, but solely to design all their parts for the work that they have to do. In spite of that, even they have gained a beauty which they never had before. It is the beauty of the machine built for speed, of the flyers of the Northern and the Eastern Railways, the thoroughbreds of the rail. I hope that some time even our automobiles will reach this point, and the first essential to this end is to make *tabula rasa* of our prejudices, and to understand finally that an automobile is a machine."

Before dealing out condemnation on the courageous author of the above words, it is fair to remember that he is writing of

racing machines only—machines whose sole purpose is "to go at such a speed for such a distance with so many passengers." It is not in the least likely that M. Sencier would elect the Austrian machine referred to for a provincial tour with his family, or would recommend it to others for that use. Nor is it probable that he or any other *chauffeur* would select the obtrusively mechanical mount in preference to a light voiturette for a spin about the parks and under the suspicious eye of the gendarmerie. But the author's real contention is sound. A vehicle, for whatever purpose, should be designed with reference to that purpose and to nothing else. In proportion to its fitness for its purpose does it satisfy the canons of true good taste. In proportion as it forsakes the intent of its use in pursuit of preconceived notions of what it ought to look like, of untutored ideas of prettiness or "shape," just so surely will the advance of enlightenment leave it a laughing-stock. The horse vehicle, in its many forms, is perfectly adapted to its use, and no one would wish to change it. Comfort, safety, and speed are alike required of the modern railway coach, and each is provided for in full measure. And what man, in whose breast the "Song of Steam" ever awoke an

echo, has looked up at the huge iron steeds that hurry the Empire State Express and the Atlantic City Flyer over the rails, at speeds unmatched in railway engineering, without a quicker pulse-beat for the tremendous harnessed force which speaks in every line?

The automobile is peculiar in that it must be locomotive and car in one, and neither function should be slighted or concealed to the enhancement of the other. In this respect it most nearly resembles the tramway car; but the tram-car's retention of the horse car's exterior has been much closer than is possible in the case of the automobile. The point to be aimed at is, not to strike a balance between two conflicting features, but to unite and harmonise them. The tramway car found its body ready to its hand, needing only to be en-

larged and strengthened. The motive power was put below the floor, on the truck; the trolley arm was mounted on the roof, and behind each dashboard—now become a wind-shield and hand rail support—was mounted a controller. The combination fulfilled its purpose perfectly, and no one calls it incongruous.

To attain the same result, the builders of motor-carriages will have to forget the horse carriages altogether, and consider simply the problem of carrying the desired number of passengers with speed, comfort, and safety, and with the minimum of effort in controlling and caring for the vehicle. The motor should be placed where it will be most accessible and will shake the carriage least, which is probably in front. The tanks, passengers, and transmission gear will then give the necessary traction. The wheels should be small or large, according to the nature of the road. The body should be as low as possible, to permit of high speed and sharp turns without upsetting. It should be no disgrace to show the cooling tubes if thereby they can be made more efficient. Machinery should be covered from dust so far as possible, but the suggestion of its presence is not a blemish, and should not be so regarded.—*The Horseless Age.*

FIG. 1.—THE BROUHOT MOTOR-PHAETON. (For description see next page.)

THE BROUHOT MOTOR-CAR.

SINCE we described the Brouhot motor-car in our issue of December 29th last, a number of changes have been made in the transmission gear, etc., and in view of the success of the modified form of vehicle at the Touring Competition in May in connection with the Paris Exhibition, a brief description of the same at the present time may not be without interest. The illustration given on the preceding page shows a four-seated phaeton. The petroleum-spirit motor employed is of the horizontal two-cylinder type, working on the Otto cycle. As will be seen from Figs. 2 and 3, the motor is suspended from and under the centre of the frame of the vehicle, the explosion chambers being at the forward end. The admission and exhaust valves are stated to be so arranged that they may be removed, for cleaning and other purposes, by loosening a single nut. Electric ignition is employed, and the cylinders are, of course, water-jacketed. The water circulation is maintained by a centrifugal pump, the fitting of a radiating coil in the fore part of the frame permitting, it is claimed, of a run of 300 kilometres to be made without it being necessary to renew the water. The motor is provided with

FIGS. 2 AND 3.—ELEVATION AND PLAN OF BROUHOT FRAME.

a centrifugal governor, which acts on the exhaust valves when the speed becomes excessive. An accelerator operated by hand is also available. The carburettor employed is of the constant level type.

A feature of the driving mechanism is that no belting or pitch chains are employed, the power being conveyed from the motor shaft to the rear road wheels entirely through spur gearing. Four speeds forward and a reverse motion are available. On the motor shaft is a hidden pinion *J*, running loose thereon. This gears with a phosphor bronze spur *K* on the end of a countershaft which carries the variable speed and reverse gear motion. This consists of a train of pinions 1, 2, 3, 5, 7, any one of which can be made to mesh with corresponding wheels on a short parallel shaft. On the outer end of the latter is a small spur wheel which transmits the power directly to a large gear wheel *M* on the rear axle. The pinion *J*, which runs loose on the engine shaft, is made solid with one-half of a special progressive friction clutch, which can be thrown in or out of engagement by either a foot pedal or hand

lever. The crank shaft and variable-speed gear work in oil containing cases.

A somewhat novel feature is introduced in connection with the rear road wheels, which are mounted loosely on the axle, no differential gear being employed. At each end of the axle circular discs are mounted, each provided with a double-pawl arrangement, the ends of the pawls being located in a notch in the boss of the discs. The wheels themselves are fitted with a ring, which forms the band brake drum, having internal teeth, this ring fitting close up against the discs in such a way that the pawl may fall in the space between two of the teeth of the ring, or may run clear of the same, according to the position of the end of the pawl in its notch in the disc. By this means, in passing round a curve, the outer wheel, having to cover a greater distance than the inside one, the toothed ring becomes released from the pawl and runs free, the inside wheel only being driven. As soon as the vehicle is again on the straight the pawl once more falls between the teeth in the toothed ring, the two wheels then being rigidly connected up to the axle and receiving impulse from the motor. The makers state that they have given this device an exhaustive trial before adopting it in their vehicles, and claim that it allows of curves being taken at a greater speed than is prudent with vehicles depending on the ordinary differential and chain gear.

Steering is controlled by a vertical hand-wheel. The frame is a combination of steel tubing and wood; the wheels are of the artillery type and are fitted with solid rubber or pneumatic tires as desired. Two brakes are provided, one actuated by a hand lever *I*, and the other by a foot pedal *H*, the application of the latter also disengaging the clutch. All the driving mechanism is suspended below the frame, thus throwing the centre of gravity low down and reducing the possibility of the car turning over, at the same time permitting different types of bodies to be fitted to the frame. Universal joints are introduced between the gear wheel and the rear axle, to allow for any inequalities in the road traversed, the two spur wheels *L M* being kept in gear by means of arms connecting the axle with the frame. Messrs. Brouhot and Co. are making engines of 5, 6, and 8 h.p., the car illustrated being fitted with one of the largest size motors.

THE North-Western Motor Vehicle Company, of Minneapolis, U.S.A., has been incorporated with a capital of £20,000.

COUNT CHARLES SEILERN has been elected a member of the A.C.G.B.I., the membership of which is now 696.

THE New England Auto-King Vehicle Company, of Portland, Me., U.S.A., has been incorporated for the purpose of manufacturing motor vehicles. The capital is £240,000.

THE toll on motor-cars passing over Maidenhead Bridge is to be considered by the Maidenhead Town Council on the expiration of the present lease of the tolls, which will shortly take place.

THE annual autumnal meetings of the Institute of British Carriage Manufacturers will be held in Dover, on September 18th, 19th, and 20th. Arrangements are being made for a party of members to go to the Paris Exhibition after the Dover meeting.

THE Providence *Journal* is making a trial of a steam vehicle built by the New England Motor Vehicle Company, of Waltham, Mass. It is of a light-wagon design, with canopy top and open sides. A sort of fence of wire netting is stretched around the stanchions, to retain the bundles of papers. The vehicle weighs 800 pounds, and will carry a load of 500 pounds besides the operator.

A TEST of a new non-slipping tire was recently made at Bridgeport by the Locomobile Company of America, in which the efficacy of the tire is said to have been demonstrated in a striking manner. An inclined plane, about 35 degrees in slope and 25 feet long, was covered with cakes of ice. A Locomobile, its rear wheels shod with non-slipping tires, and carrying two men, was driven under its own steam to the top of the slope, where it was held by the brake while photographs were taken. The new tire carries small steel spurs, not large enough to interfere with the use of the tire in the ordinary snow, etc., of winter streets, but yet sufficient to pierce the ice and be held.

RECORD-BREAKING IN AMERICA.

THE best thing in the way of an automobile story which has yet come to light in Boston is that afforded by Mr. William K. Vanderbilt, jun.'s flying trip from Newport to Boston and return on Friday, July 20th. It really astonished the natives, and, best of all, states the *Horseless Age*, it was true. His wonderful Daimler carriage, regarded as a marvel from the newspaper accounts of it, was even more wonderful to those who caught a glimpse of it. They could get no more than a glimpse, for it was disappearing like a flash in the distance before any of them could get a second look. Incidentally, Mr. Vanderbilt established a new record over the road between Newport and Boston. General Manager Dwight Neftel, of the Electric Vehicle Company, and George McQuesten, an East Boston lumber dealer, made the trip in one of the company's new runabouts, equipped with a long-distance battery, on a single charge, on Monday, July 2nd, in five hours and eighteen minutes; but that run, though pretty good for an electric carriage, was nothing to the Vanderbilt achievement. Mr. Vanderbilt left his stable at Newport at 6.30 a.m., and arrived in Boston shortly before nine o'clock, making the run of 72 miles in two hours and eighteen minutes, at a rate of speed averaging 31.3 miles an hour, or a mile in less than two minutes.

In Fall River there are three miles of very sandy road, over which the machine could not make its usual speed, but the delay in this place was compensated for in the run into Boston. On Blue Hill Avenue the speed register attached to the machine showed 65 miles an hour. As there is not much road about Boston adapted to such high speed, the run into the city proper was probably at a speed below 20 miles an hour.

Mr. Vanderbilt's run to Boston was merely a pleasure trip, and he stopped there not more than an hour. While in the city he remained at the headquarters of the New England Electric Vehicle Company on Tremont Street, and as soon as the petrol tanks were refilled and the tires inflated, he started on the return trip, with the expectation of reaching Newport in time for luncheon, if he did not conclude to continue over the road to New York. With Mr. Vanderbilt was his *mécanicien*, whom he brought with the machine from France. When mounted upon the machine prepared for a run, the two men looked as if they expected to meet a rain or dust storm, but in reality they were taking only the usual precautions adopted for fast automobile driving. Both men wore visored caps, something after the style of a yachting cap; heavy coats buttoned up to the throat, gauntlet gloves, and goggles over the eyes. From the sloping dasher a white rubber boot was buttoned up under the arms of the men. This boot, with the dasher, serves to cut through the air and throw it above the heads of the passengers. After running slowly down the incline, from the automobile company's station to Tremont Street, the machine was headed south and was off in a flash, disappearing almost before one could realise that it had started.

This machine of Mr. Vanderbilt's is, perhaps, the most interesting racing carriage in America. There is said to be only one other that equals it in speed in the world, and that is owned by a French count. Mr. Vanderbilt bought his in France at an original cost, it is said, of between 5,000 dols. and 6,000 dols.; and, up to date, the total cost is probably not far from 10,000 dols., for the owner has no regard for expense, and if he wants to stop quickly he does not hesitate to strip off a pair of tires.

Furthermore, if the police of Newport enforce the speed law, Mr. Vanderbilt will probably have an additional expense of 10 dols. to 20 dols. a day for fines, and he has told the police that they have the privilege of arresting him as often as they wish. The carriage has engines of between 30 and 35 h.p. The wheels have French inner-tube tires, 3in. in diameter on front and 5in. on the rear wheels. Extra tires are always carried on the box behind. When running at top speed the machine can be stopped within 100 yards without injury. It has five different brakes, and by reversing the engine the wheels can be locked. When this is done, however, it is necessary to have a new set of tires all

ready to put on. The fly-wheel of the engine acts as a fan, and draws air from the front of the carriage through ducts. This air passing through at great speed cools the water radiator. When the machine was imported it was painted white. Now Mr. Vanderbilt has had it painted crimson and black.

SOME NEW MOTOR-BICYCLES.

A MOTOR-BICYCLE of Bohemian construction is shown in Fig. 1. It is known as the "Republic," and is made by Messrs. Laurin and Klement, of Jungbunzlau. As will be seen, the frame is of special construction. The motor is mounted within, and in the fore part of the frame immediately over the carburettor (3). The petrol tank is built in the rear half of the frame (2). The power of the engine is transmitted to the drum (5) attached to the rear wheel by a leather strap; so that the strap shall not interfere with the pedals an idle pulley is mounted on the main down tube of the frame. The engine is

FIG. 1.—THE "REPUBLIC" MOTOR-BICYCLE.

air-cooled, and is fitted with electrical ignition; it is made in two sizes, either 1½ h.p. or 1¾ h.p., being fitted as desired. A powerful hand brake on the front hub is provided, while the rims are fitted with 2in. pneumatic tires. The machine can, it is stated, attain a speed of 35 miles per hour on level roads.

Still another motor-bicycle has been put on the French market. This is the "Centenari," of which an illustration is given in Fig. 2. As will be seen, the motor is attached to the head of the machine, as in the case of the Werner, but the power is transmitted to the rear wheel. This is effected by belt and

FIG. 2.—THE "CENTENARI" MOTOR-BICYCLE.

chain gearing. The back-frame is of special construction, to allow of a pulley and chain wheel being mounted just below the saddle. A small belt connects the motor with the pulley, a chain transmitting the power from the latter to the rear axle. The motor, which weighs 8 kilog., or about 17½ lb., is said to develop 1½ h.p. when running at 1,600 revolutions per minute. The rider has, it is stated, only one tap or handle to manipulate—that controlling the variable electrical ignition. The machine can, it is stated, attain a speed of 60 kilomètres per hour on the level, and mount gradients of 12 per cent.

MOTOR-CAR TRIP.

FROM EASTBOURNE TO PEVENSEY.

CHARTER one of the Pioneer motor-cars and go on Pevensey Castle. Keep your eyes and your ears open, and when you get back write a column or so on what you have seen." So spake my Editor on Friday afternoon. Before he had time to countermand the order I was through the office door and on the car "Duchess," which starts its journeys from just outside the office; and in a couple of minutes I was well out of sight, careering down Seaside Road.

The Eastbournian who has not had a trip on one of these motor-cars has lived in vain. The man who has been will go again. To describe the delightful sensation of rushing through the air almost noiselessly is impossible. The nearest approach to it is the feeling one has on a railway engine or up in a balloon. I have tried all three. I have travelled over sixty miles an hour on an express engine in the night, and I have been a mile high in the air. Both experiences were fascinating, but my preference lies with the motor-car. Perhaps I am a bit of a coward at heart, and prefer the safer mode of travelling. So be it. As against that charge, however, let me set forth one or two points. I have descended pit shafts over two or three hundred yards deep; I have gone out in the lifeboat in a gale; and I have ventured into matrimony!

But there, let me describe my run. Well, it seemed to me that we were in Pevensey in no time. Yet we had driven along pleasant lanes and amid a pleasant landscape, with the sea close at hand upon our right, and Hastings' high hill frowning upon us from across the bay. The car seemed a living thing, for as it sped along it quivered like a thoroughbred, and sent forth a humming sound like the buzz of a swarm of bees—not at all an unpleasant music. And of the smell that some people complain of in connection with the motor-car, I did not detect a trace.

Presently we reached the pretty village, lying in the shadow of its two massive churches and of the mouldering walls and round towers of the ancient fortress. Here Julius Cæsar landed fifty-five years before the Christian Era, and here another invader, William of Normandy, first set his mailed foot on British soil in 1066, and burned his boats. Owls and bats are now the only living denizens of the castle whose floors once rang with the martial clang of the tread of armed warriors. On the journey back I chatted with the driver as to why the Eastbourne Corporation prevented the motor-cars going along the front. He could only think it was done in the interest of certain interested parties, who shall be nameless.—From *Eastbourne Society*.

THE Committee on Chemical Hazards of the New England Insurance Exchange in America has adopted a permit for the storage of petrol motor-cars. The permit, which has still to be submitted to a general meeting, will, if approved, carry with it a small additional insurance charge.

MESSRS. CRAMPTON AND CO., electrical engineers, of Great Yarmouth, Cambridge, and Bury St. Edmunds, have opened offices at 77A, Queen Victoria Street, London, E.C., which will be used chiefly as the estimating department for complete electric lighting plants and power installations.

THE Metropolitan Motor Manufacturing Company, Limited, has been registered, with a capital of £10,000, to acquire certain inventions from Messrs. A. E. Creese, F. Jackson, and T. Underwood, and to carry on the business of electrical and general engineers, motor-car manufacturers, etc.

MR. A. MARMADUKE HART, of Woolwich, is preparing to place on the market a new sparking plug, the feature of which is that the parts are so made that any of them can be readily renewed, even on the road, the joints being made without the use of solder or cement.

SUIT has been brought by the Electric Vehicle Company and Mr. George B. Selden against the Winton Motor Carriage Company, of Cleveland, O., for alleged infringement of the now famous Selden patent. The case will be tried in the United States Circuit Court of the Southern District of New York, probably some time during the autumn.

THE "STELLA" VOITURETTE.

ONE of the latest voiturettes to appeal for public favour is the "Stella," of which an illustration is given herewith. The body is entirely independent of the frame, which is of tubular construction, it being suspended fore and aft on C springs. It can be adapted for two or three persons as desired, the choice of the motor being also permitted to the purchaser between a 2½ h.p. air-cooled Aster, a 3 h.p. water-cooled Aster, or a 3 h.p. water-cooled De Dion. The engine is geared to the rear axle through a special two-speed gear and clutch, illustrated in Fig. 1 and described below.

The new gear, which has been devised by M. H. Gerard, is a progressive apparatus of simple construction, in which are grouped several ratios of speed, each of which is obtained through an epicycloidal train, of which the gearings are always in engagement. It comprises two trains, each of which consists of: (1) A central pinion, *P P'*, keyed upon the driving shaft; (2) three spur-wheels, *S S' S''*; and (3) an internal gear, *B B'*, the periphery of which is provided with a groove for the reception

FIG. 1.—SECTIONAL VIEW OF VARIABLE-SPEED GEAR "STELLA" VOITURETTE.

and guiding of the brake straps. The axles, *I*, of the spur-wheels are secured to the external plates, *F F'*, one of which, *F*, carries at the extremity of a socket a pinion, *A*, that meshes with the toothed wheel of the differential and transmits motion to the driving wheels. The gear wheels of each train are supported and held at an immutable distance by revolving discs, *R*, fixed laterally. When the motor is in operation, the tightening of one of the brakes renders one of the internal gears immovable, and the central pinion keyed upon the driving shaft revolves the spur-wheels, which, taking a purchase upon the stationary internal gear, carry along the axles, external plates and pinion *A* at a differential speed that depends upon the ratio of the gearings. The other train will remain idle; and one speed will be obtained. When the second train is rendered immovable, the first will be freed; and, as the ratio of the gearings is different, we shall have a second speed. When the two brakes are free, the pinion *A*, the plates *F F'*, and the axles will remain stationary as a consequence of the resistance of the carriage, and the spur-wheels will revolve, along with the internal gear, in a direction reverse to that of the running of the motor. The driving mechanism will thus be thrown out of gear. With this apparatus the makers claim it to be possible to throw the mechanism into gear progressively and with the greatest ease, without any fear of stopping the motor (even on a

declivity); to change from one speed to another, and to throw the mechanism out of gear without the least shock and as gently as may be desired, since the braking of the speeds is dependent upon the will of the driver. There is no danger of a breakage of the cogs, since the gearings are always in engagement. Moreover, the discs that support the gearings prevent the cogs from meshing too deeply and becoming wedged, and constitute rollers that have the same effect as a ball-bearing mounting, in rendering the revolution of the wheels easy, and in suppressing noise and wear.

Steering is controlled by an inclined hand-wheel, on which is mounted a small electric current interrupter; the handles or taps for varying the carburation and ignition are mounted on the steering column. An arrangement is also provided which enables the engine to be started from the driver's seat. The car, which is provided with cycle-type wheels and pneumatic tires, weighs a little over 3 cwt., and can, it is stated, attain a speed of 35 kilometres per hour on the level, and mount any ordinary hill at a speed ranging from 8 to 16 kilometres. It is made by La Société de Constructions Mécaniques "Stella," of Levallois-Perret, France.

TUBE VERSUS ELECTRIC IGNITION.

THE incandescent tube occupies an earlier place in the evolution of the gas engine than the electric spark. It is so ideally simple, as regards both construction and care, and so uniformly reliable under any ordinary conditions, that the preference given it has been obvious and natural. Being surrounded by flame, it does not, like the electric sparker, need to be protected from the heat within the cylinder. It can be fouled only by an inordinate excess of oil. Its timing is practically invariable. It has no hidden or mysterious weaknesses, and if made of platinum or nickel alloy it is almost indestructible.

The user of electric ignition, on the other hand, must be something both of an electrician and of a mechanic to care for it intelligently. Battery exhaustion, corroded wires, short circuits anywhere from battery to contact points, "grounds" and fouled or worn contacts, are a few of the infirmities common to the class; and each type has its own pet ailments besides. The "jump spark" igniter will get out of order most often from the difficulty of confining the high potential secondary current. The "wipe" sparker is not readily fouled, but its timing is apt to be affected by wear, and the tips need frequent renewal. The "lift" sparker, if the contact is broken by the piston or by the rise of a cam, is sluggish, and at moderate speeds requires a heavy current. It has the fatal defect of giving its poorest spark when a strong one is most needed, namely, when starting the engine; and it should never be used where portability and battery economy are important. The quick-acting lift sparker, with contact broken by the snap cam or trigger release, is the most complex type of sparker. It gives a uniformly good spark at all speeds, however; it is very economical of current, and if it gets out of order it is usually outside the cylinder and not inside. It does not lose its correct timing by wear, as the piston lifted and wipe sparkers nearly always must, and, when once adjusted, it may be left indefinitely.

Nevertheless, even the most perfect electric igniter has many more ways of getting out of order than an incandescent tube; and if the only drawbacks to the latter were the cost of keeping it hot by an external flame and the perhaps rather imaginary danger from fire, it is doubtful if such persistent attempts would be made by the builders of motor-carriages to improve the electric igniter, to the neglect of the tube. But the real obstacle to the employment of the latter on vehicle-motors is that the high-speed gas engine demands a considerable lead in its ignition, and by preference one that is automatically variable for different speeds; and this the incandescent tube cannot give. Less than could be wished is known concerning what actually takes place in the tube at each point of the cycle; but it is now believed that the fresh mixture reaches the heated portion of the tube and is ignited considerably before the end of compression stroke. The flame is then prevented from striking back into the cylinder by the continued inflow of fresh mixture, and the flame only reaches the mouth of the tube when the inflow becomes slower than the rate of flame propagation—i.e., when the compression stroke is near its end. It is known that the external flame can, without pre-ignition, be applied to the tube at a point which calculation shows must comparatively soon be reached by fresh mixture; and this fact is taken advantage of to relieve the compression somewhat when starting the engine.

This action within the tube has the effect of causing inflammation of the mixture to begin shortly before the crank reaches the centre, with almost any moderate speed of rotation. Unfortunately, the inflammation tends to lag as the speed increases; and at high speeds it is nearly impossible with tubes of the usual proportions to get it started soon enough to insure complete combustion before the mixture has expanded too far. Naturally, these phenomena are most marked with long tubes, and by making the tubes sufficiently

FIG. 2.—THE "STELLA" VOITURETTE. (See opposite page.)

short the velocity of inflow may be reduced to any desired extent, and inflammation begun at a point correspondingly early. This is the method adopted by a prominent firm of launch builders which employs tube ignition and high speed, but in practice it is extremely unsatisfactory. In proportion as the tube is shortened, the time when inflammation begins becomes less and less self-regulating, and at length depends solely on the degree of compression and the richness of the mixture. Consequently, anything which affects the compression, such as a dry piston, clogged inlet pipe, change in spring on inlet valve, or even a change in speed when the piston is drawing air rapidly through a constricted opening, or any change in the mixture, such as half a dozen things may cause, will result in an ignition either too early or too late, or in no ignition at all. Moreover, the operation of starting becomes a very delicate one. This defect of kicking back could be corrected by a timing valve to open and close the mouth of the tube, and in England these are much used on stationary engines. They have found little favour in America, however, and for vehicle service, at least, it is doubtful if any form could be devised whose advantages would overcome the defects of its added complexity.

It is often thought that the incandescent tube gives a more certain ignition than the spark, and it is unquestionably easy to find cases in which the inflammation propagates more rapidly from

the tube than from the spark. This is probably attributable to the relatively large igniting surface presented by the former, as compared with the minute dimensions of the spark; but the energy of the spark has much more to do with the rapidity of combustion than is sometimes supposed. It is well known that a poor mixture requires a strong spark, but it is not so commonly understood that a spark which is quite sufficient at slow speed will fail to burn the charge fast enough when the engine's speed is considerably increased. Within limits this can be compensated for by increasing the lead; but the lead, while necessary, should, for the best efficiency, be no greater than needful; and it may be set down as a rule that all high-speed engines should have a strong spark.

We see, therefore, that, despite its simplicity and dependability, there are other reasons for the incandescent tube's disbarment from vehicles than the fear of our *chauffeurs* lest they be "blown up" in the midst of their sport. For the reasons given, only the most efficient types of sparkers can be justified in its place; but the logic of the situation points to the development of the electric igniter, in spite of the problem it presents, rather than to the retention of the simpler but less adapted incandescent tube.—By Herbert L. Towle, in the *Horseless Age*.

AN EARLY ELECTRICAL VEHICLE.

ELECTRICITY has come so much to the front in recent times that there are but few who stop to think of the great changes it has wrought during the past twenty years. Turning over some old papers the other day we came across the accompanying illustration of an electric tricycle said to be the first ever propelled and lighted by means of accumulators. The following account of the vehicle is taken from the *Graphic* of December 23rd, 1882:—"The latest development in the use of accumulators is the electric tricycle of Professors Ayrton and Perry. No work is done by the rider; the little black boxes, *S*, carried on the base board, contain the stored electric energy pretty much in the same way as a horse's body contains its breakfast of oats and hay—with this difference, that in the accumulator it is the receptacle alone which has weight, so that neither on receiving its feed in the morning nor in discharging its power during the day does the accumulator gain or lose in weight. The rider sits on the seat (shown in section in the illustration) with the steering handle *G* in his right hand, and with his left on the electric supply tap *C*. If he wishes to go faster or uphill he turns on the tap a little, lets the electricity run out of the boxes faster, and thus causes the motor *M* to work more powerfully; while, on the contrary, if he is going along the level, or down hill, he can shut off the supply tap more or less. Indeed, in some cases, we understand that the inventors have arranged that, in going down hill, the electro-motor which generally uses up electric power is converted temporarily into a generator and furnishes electric power, thus charging up the accumulators and acting as a brake. The economy arising from this double function of the motor is analogous with what would occur if, when an ordinary carriage went down hill, putting on the brake not only hooked the nosebag on to the horse, but generated the oats necessary to fill it up for each feed.

"The motor seen under the seat in our illustration, although small enough to be used in a tricycle, is exactly of the same size as that used to drive a twelve-foot metal lathe, and hence an idea can be formed of the power it can exert. The present electric tricycle is a converted one, that is, the ordinary foot treadles and chain gearing have been replaced by the electric arrangements; but we understand that the inventors, encouraged by the success of this first machine, have designed a strong light tricycle, especially adapted for being worked with their patent electric motor, fed by accumulators. With the present converted tricycle, when weighted with a rider of average weight, and with sufficient accumulators to propel it for two hours, the measured mile can be run in eight and three-quarter minutes, corresponding with a speed of nearly seven miles an hour. The actual horse-power which is being expended at any moment is seen from the readings on the ammeter *A* and voltmeter *V*.

"Another peculiarity of the electric tricycle is that when going at the highest speed, although the consumption of the power is greater than when going slowly on the same road, the waste of electricity is much less, that is, the faster it goes the more efficient is the whole arrangement. On the other hand, when the electric supply tap is turned off, and the tricycle is at rest, the waste in the accumulators is very small, the tricycle stands for days ready for immediate use, and there is no waste analogous with that of an unused horse eating his head off.

"But although an electric tricycle ceases using up its last meal of electricity directly it stops, and requires no feeding while motionless, still it must be fed periodically if used regularly. Until the time when the tricyclist can dismount at his inn with the certainty that in the morning he will find his accumulator

fully charged up with the electric machine of the inn, also used for lighting and agricultural purposes, electric tricycle tours must be limited. But when that time (not probably so very far in the future) arrives, the tricyclist will find the charge in his bill for the electric feed one of the smallest of the items entered."

A BUTTON which may be worn on their coats by members only (and not by their servants) has been adopted by the Automobile Club. The regulations as to wearing the button are the same as those which apply to the wearing of the Club badge. The button is black with a small monogram of the club in gold.

THE Rev. Dr. Minot J. Savage, in company with Mr. Roland R. Conklin and family, of New York, have just returned from an automobile tour through Normandy, Brittany, and Touraine. Mr. Conklin brought his automobile with him from America, where it was built. The car, which is especially adapted for long touring trips, holds six persons, as well as baggage. Mr. Conklin and family will remain in France until the middle of September, and are contemplating a tour in the Pyrenees before their departure.

THE British Consul at Munich, Bavaria, in his recently-issued report remarks that, "Until May last only twenty-five duly licensed automobiles, whose drivers had given satisfactory proof of their skill to the police authorities, were allowed to circulate in Munich, but the restriction as to the number has now been withdrawn. A maximum of 12 kilometres per hour (about 7½ miles) is proposed to be adopted in the town, but certain streets are prohibited, and when passing through archways, automobiles must travel at a foot's pace. Visitors should buy a plan of the town with the prohibited streets marked in red."

MOTOR-CARS ON THE CONTINENT.

(From Our Own Correspondent.)

An American Automobilist.

It will doubtless be remembered that in May last a certain Mr. Albert C. Bostwick purchased M. René de Knyff's "Tour de France" car, the price paid being quoted as £2,400. Later on in the year, or, to be exact, during the first week of June, Mr. Bostwick covered himself with glory in the Bordeaux-Perigueux-Bordeaux, when he steered the Panhard into third place, the men in front of him being M. Levegh on his this year's Mors, and M. Giraud on the new Panhard. After a few months' experience of French automobilism, Mr. Bostwick has now returned to New York, taking with him not only his own Winton car, which he brought to Europe, but also the "Tour de France" winner and three other Panhard vehicles, as well as a motor-tricycle.

A Costly Car.

APROPOS of high prices paid for racing cars, I learned the other day that Lord Carnarvon had purchased M. Charron's winner of the Gordon-Bennett cup and the same car that M. Voigt drove into second place of the Paris-Toulouse course. The price paid, I am told, was 75,000 francs, or £3,000.

The Voiturette Competition.

It is on Monday next, the 13th instant, that the Voiturette competition organised by the Automobile Club of France, under the direction of the Exhibition authorities, will commence at Vincennes, and during five days the gallant little vehicles will be put through their paces. As in previous contests of this class, the jury will base their report and adjudge the awards upon the following points:—1, The consumption of fuel or of energy; 2, the working of the motor; 3, the facility of steering; 4, the brakes; 5, the comfort of the vehicle. A couple of categories are provided for by the governing regulations, the one reserved for vehicles not exceeding 250 kilogrammes in weight unloaded and provided with two seats side by side, the other for two-seated cars weighing unloaded 400 kilogrammes or less. The latter class is required to be fitted with a reverse gear. Two routes have been selected by the organisers, and the competitors will be required to cover each itinerary two or three times and in the order directed by the jury. Each route is of about 160 kilomètres in length, and the cars will make some 63 kilomètres in the morning and complete the journey during the afternoon. The speed will not be permitted to exceed 30 kilomètres per hour, but over certain portions of the route the vehicles will be timed. However interesting these competitions may be to those interested in the automobile industry, the general public takes but little interest in them, and nothing but a race attracts a crowd of anything like respectable dimensions.

Certificates of Capacity in Paris.

ONE effect of the activity displayed by the Parisian police ever since April last is the enormous increase of applications for driving licences, as shown by the official figures recently published by *Le Vélo*. Formerly two-thirds of the men who motored simply chanced matters and went to no trouble whatever to obtain the legal authorisation, but all this is changed, and automobilists are now applying in their hundreds for permission to conduct their oily steeds. And, after all, what is it? A certain amount of trouble in gathering together the various papers and a tiresome wait of some weeks until it graciously pleases the examiner to call upon one to demonstrate his skill, or lack of it. That is all. But, apart from these drawbacks, the affair is a mere trifle and the examination only a short run with an agreeable companion. Personally, I am entirely in favour of the examination system, and the sooner that it is adopted in England the better will it be for all connected with

the industry and the sport. Its enforcement in England should certainly do something to prevent the occurrence of those accidents arising from the impetuosity of the embryo *chauffeur*, whose delight at driving a car for the first time outruns his skill and discretion. How often does one see that Mr. So-and-So, having just bought a car, was making in it his first run when the accident occurred? Why, frequently; and all this might be avoided by the enforcement of an examination. Here in France the demands this year as compared with the like period in 1899 are as follows:—

	1899.	1900.
April	114	318
May	206	780
June	135	312
	455	1,410

or an increase of nearly 1,000 *chauffeurs* duly licensed to promenade *en automobile*.

THE "CYCLOPE" VERTICAL PETROLEUM-SPIRIT MOTOR.

IN our issue of July 21st last we published an illustrated description of the Augé petrol car, which is fitted with a two-cylinder horizontal motor of 5 h.p. This engine, which comprises several special features, is now being made in the vertical form, as shown in the accompanying illustration. The

cylinders are, of course, water-jacketed, while electrical ignition is adopted. The normal speed of the motor is 600 revolutions per minute, but by means of the variable ignition this can be regulated as desired between 300 and 1,200 revolutions. Messrs. Daniel Augé and Co., of Levallois-Perret (Seine), France, are the makers.

MR. T. BURT, of Commercial Road, Totton, whose dépôt is on the main road from London to Bournemouth, is now carrying a stock of motor-car spirit.

THE Touring Club of Belgium is organising a touring congress, to be held at the Belgian Pavilion of the Paris Exhibition on the 13th inst. One of the objects of the congress will be to overcome the difficulties which official formalities now put in the way of automobilists in foreign countries.

AN electric omnibus, the necessary current for which is taken from an overhead conductor on the same lines as that adopted for electric tramways, was put in operation at the Vincennes annex of the Paris Exhibition last week. The system is due to Messrs. Lombard and Gerin.

MOTOR CARS IN AUSTRALIA.

(From Our Own Correspondent.)

MELBOURNE, JULY 3RD.

MATTERS are now beginning to liven up a bit in the way of motor-vehicles, there being quite a number running, including a French voiturette and a locomobile. The latter, however, received a scorching the other day from the burner flooding, causing the gasoline tank to go. As this is the third motor car fire we have had it is hardly to be wondered that the public are a little doubtful as to their safety. From the little I saw of this car I am of the opinion that it is too much of a toy for the roads in this colony, which from their unmade condition require strongly-built cars in order to give satisfaction. Gasoline at from 2s. 9d. to 5s. 6d per gallon is rather too much to preserve economy, more especially as it is only to be procured in the capitals. This, no doubt, accounts for so few of the motor-tricycles being used, although there are a dozen or more in Melbourne.

The Thomson car has now been registered as "The Thomson Motor Car, Limited," and I hear that two light cars to seat two or three are being built. These cars are to have double compound engines, developing up to 10 h.p., and will use kerosene oil fuel. Bulk receivers are now being erected in Melbourne for the importation of kerosene in tank steamers, which must have a cheapening effect on the oil market, and add to the value of a motor-car using liquid fuel.

A Sydney house has imported a voiturette, which they are listing at £262 10s. (250 guineas). As I understand there is no duty on these in New South Wales, it seems that too much profit is trying to be made. This is rather a pity, for it gives the general public the impression that motor-cars are an expensive luxury and creates a depressing effect on likely supporters.

FAILING TO STOP.

AT Ke-steven Petty Sessions, held at Lincoln last week, Reginald G. Williams, of Lincoln, employed by Mr. K. M. Wright, was summoned for not pulling up a motor-car of which he was the driver, when requested to do so. The case was proved by Superintendent Clarke, who said that he put up his hand, but the defendant did not pull up, and the result was that his horse would have bolted had not Superintendent Dain held its head. Defendant contended that he did not see the uplifted hand until he was forty yards away. The magistrates described the case as a serious one, and fined the defendant £2.

FURIOUS DRIVING CASES.

BEFORE the Kidderminster Borough Bench, last week, Rupert Turner, motor-car driver to Mr. Howard Jobson, of Summer Hill, was charged with having driven furiously down Bewdley Hill on July 25th. Mr. Spencer Thursfield defended. P.C. Wilson said the car was driven at a rate, in his opinion, of eighteen or twenty miles an hour. Witness shouted, and after some little time defendant stopped, but went on again. He subsequently saw defendant, who admitted that probably he was going beyond the regular pace. Mr. Thursfield said Mr. Jobson's instructions were to drive slowly, and on that particular day, as the governess and children were in the car, Mr. Jobson told Turner to be careful. Mr. Jobson was sorry that the proper pace should be exceeded. He asked the Bench if they could take the course of allowing the case to be withdrawn on payment of costs. The Mayor said there was no desire to check the development of the motor-car industry, and they were ready to assent to the course suggested, but drivers of motor-cars must be careful in the town. He suggested that in addition to the payment of costs a contribution should be made to the poor box. Mr. Thursfield paid the costs, 9s., incurred, and gave half a guinea for the police poor box.

At the Bournemouth Police-court, last week, William Henry Butler, a motor-car driver, was summoned for driving a motor-car at speed greater than was reasonable and proper in Old Christchurch Road on 21st July, having regard to the traffic on the said highway. Defendant, who was represented by Mr. E. H. Bone, pleaded not guilty. Police-constable Baugh said that at twenty past two o'clock on the day in question he was standing near the cabstand opposite Firs Glen, when he saw two motor-cars coming down Old Christchurch Road from the direction of Holy Trinity Church. The front car was driven by a man named McArdle, and defendant was in charge of the other. They ran at the rather brisk pace of eight to ten miles an hour until they arrived opposite the cab stand, when suddenly Butler pulled out behind McArdle's car and dashed by at the rate of twelve to fifteen miles an hour, and before he had gone far he obtained a lead of

two or three hundred yards. When spoken to on a later day defendant said he did not know that he was going particularly fast, and explained that his car was geared higher than the other. Having regard to the traffic in the road at the time and the fact that defendant was very much to the right of the road, witness considered the pace dangerous. Sergeant Thomas said he noticed defendant laugh at McArdle as he "swung" by him. He considered the pace dangerous. He put the pace at twelve to fifteen miles an hour. Cross-examined: Defendant's car belonged to the Canford Cliffs Company. He did not think any driver employed by that company had ever before been prosecuted. William John Masters, a cabman, gave corroborative evidence. Mr. Bone: Motor-cars do drive quickly, don't they? Witness: Quicker than we are allowed to drive. Mr. Bone: And that is the grievance? Witness: It does not grieve me. Mr. Bone urged that defendant did not cause the least interference with the traffic on the highway. The car could not travel at a greater speed than twelve miles an hour, and defendant in the alleged offence was passing a car the utmost speed of which was ten miles. The statute allowed these motor cars to run at a maximum speed of twelve miles an hour. He urged that the evidence showed that the witnesses had an aversion to motor cars generally. Defendant, who said he was formerly employed by the Electrical Cab Company, London, gave evidence on his own behalf, and said he passed McArdle's car in the ordinary way, and could not possibly have gone at a greater speed than nine miles an hour at the spot in question on account of the rise of the road. The road was clear when he passed McArdle. Going at the rate of twelve miles an hour he could stop the car within a space of nine feet, the length of the vehicle. He denied any intention of racing with McArdle. Frank Holloway, secretary of the Canford Cliffs Motor Omnibus Company, said when defendant's car was in perfect condition it could not possibly run more than twelve miles an hour. Superintendent Foster objected to this evidence, and the Mayor agreed that what the Bench had to decide was whether the car was driven at a speed which was unsafe. The Bench convicted, but taking into consideration that defendant had never before been summoned, he was only fined 5s., and 14s. 6d. costs. The Mayor said there was no doubt that motor-cars were driven at too great a rate through the town. It had been spoken of in the Council, and by different people. He hoped the drivers would drive more steadily in the future, or there would certainly be a bad accident.

Charles Laner, who had driven a motor-car from Hull, bringing a friend with him, was summoned to the Bridlington Petty Sessions on Saturday for furious driving on Sunday evening, the 29th ult. It was proved by P.C.'s Robson and Lownsbrough, as well as by several residents, that on the evening in question, when the streets were crowded, the defendant went round a large lamp two or three times at a rate of ten or twelve miles an hour. John Coward, a cabman, saw the strange pirouetting of "the man with the motor-car." Mr. T. Hart, of Hull, said that the defendant ran the machine round the lamp to get an ignition. He was pedalling, as one of the working parts was broken, and consequently he could not get up a speed of more than four or five miles an hour. Colonel Hudson, the presiding magistrate, said there was no need for the defendant to ride round the lamp-post, causing people to run to get out of the way, and he would be fined £1 and costs.

SIR HENRY ROBINSON, Chairman of the Irish Local Government Board, has entered the ranks of automobilists.

THE Montreal Automobile Company, of Montréal, Canada, with a capital of £50,000, has applied for a charter of incorporation.

A LEGAL work, "The Law and Practice relating to Letters Patent for Inventions," by Mr. Roger W. Wallace, Q.C., and Mr. J. B. Williamson, was published last week.

WORTHING has licensed a number of motor-cars for sixpenny trips into the country, and many visitors are availing themselves of the vehicles.

INCLUDED among the papers to be read at the International Congress on Hygiene and Demography, at present being held in Paris, is one by Dr. Briand on "Hygiene and the Automobilist."

IN answer to "T. S." and other enquirers the address of the maker of the Centaure bicycle, illustrated in our last issue, is M. Flinois, 205, Rue de Flandre, Paris.

La Locomotion Automobile announces that the Darracq Company, of Suresnes, Paris, have just completed the construction of a 50 h.p. racing car.

A NEW cycle track is to be opened at Navan, Ireland, on the 15th inst., when a race meeting will be held. Included in the programme is a five-mile motor-cycle race—the first to be held in Ireland. The new track is a cinder-surfaced one.

APPLICATION is to be made for a charter for the Canadian Motor-Vehicle and Battery Company, with a capital of £40,000. Hamilton, Ont., will be the headquarters of the company, which proposes to manufacture motors and storage batteries, and build electric and petrol automobiles.

THE Motor-Car Journal.

Vol. II.]

LONDON, SATURDAY, AUGUST 18, 1900.

[No. 76.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

IT was only early in June last that H.R.H. the Prince of Wales received delivery of his 6 h.p. Daimler phaeton. Since then he has had several trips on his car, and is apparently more than ever impressed with the advantages of automobiles, not only from the point of view of sport, but also as regards their advantages on the practical side, for we learn that the Daimler Motor Company are at present engaged on the construction of two additional cars to the order of the Royal *chauffeur*. One of the vehicles will take the form of a 12 h.p. wagonette with seating accommodation for eight persons, while the other will be a fourteen-seated car of special

design, the front seat—for three persons—being located directly over the engine. The latter vehicle, the body of which will be of wagonette form, is intended for the use of gun loaders and servants, and is to be used in connection with the Royal shooting parties.

A Whitsun Tour in Ireland.

THE interesting description of the recent motor-car tour through Ireland has caused in the mind of many motorists a keen desire to visit the sister isle, and several friends have spoken to us on the subject, urging the importance of endeavouring to arrange a trip next Whitsuntide, to last for say a fortnight. Such a trip, we are convinced, would be most popular, and of its success there could be no doubt, but we are afraid the organisation of such an excursion would be outside the province of the proprietors of this journal. Personally, the writer, while confessedly knowing nothing of the roads, and little of the geography of Ireland, would be delighted to assist any organisers in such a scheme; but he is of opinion that these matters of organisation are best left in the capable hands of the Automobile Club. As a matter of fact, the subject of an Irish tour has often been discussed in the smoke room of the club by members, and favourable opinions have been expressed of the beauties of such a tour. That it would be successful there is not the slightest doubt, and that it would prove the most popular and pleasant of all the enjoyable trips organised by the Club we most certainly believe.

The Behaviour of Motorists.

OFTEN have automobilists been urged to be considerate with regard to nervous horses and equally nervous drivers, and in ninety-eight cases out of a hundred courtesy and thoughtfulness are the rule. Unfortunately, there are some motorists who are as heedless of the rights of the road as are some drivers and riders of horses, and the result is to bring discredit upon all interested in the new pastime. Such action is rarely to be

laid to the charge of automobilists, and that is well. For whenever devotees of the motor-car are guilty of anything savouring of incivility it is blazoned abroad, and even made the subject of discussion by local authorities.

Morpeth and Motors.

SUCH a case has just happened at Morpeth, where the Highway Committee of the local Rural District Council have secured the unanimous adoption of a resolution to urge the County Council to "protect the public against the increasing motor-car traffic." It appears there have lately been two regrettable accidents in that locality, and in each case the motorist concerned went on his way never heeding the dangerous condition of those he had overtaken. The chairman of the district council urged that motor-cars should be conspicuously numbered, so that the identification of the delinquents could be made possible. There is no doubt that great harm is being done by thoughtless drivers, and the sooner they carry out the Automobile Club's injunction to reasonableness and gentlemanly behaviour the better for the future of the industry.

Touring in the West.

TOURING by motor-car is well to the fore this year, and it is certainly astonishing in what out-of-the-way places automobiles are seen. In the West Country—on the moors—several have been met during the last fortnight. The horses we find, as a rule, are somewhat troublesome, and the narrow lanes render the question of "hacking" a matter of courtesy on one side or the other. The West countryman, as a rule, however, does not lose his temper, but rather seems to enjoy the antics of his horses. Possibly he knows them. We may mention that many of the main roads of Cornwall are in very fine condition just now, although they will be found rather hilly. The lanes and cross-country roads are usually loose, and frequently very steep and narrow. Devon roads and lanes are well known. They are narrow, with steep inclines, winding declines, and tortuous to a degree in their windings.

Collision at Torquay.

THE Singers of Paignton are well known to the motor world, and, as a rule, the family largely use one or other of their several cars in their journeyings about the neighbourhood. On Monday last one of their cars was driven to Torquay, where some purchases were made. The car contained Mrs. Paris Singer, her mother, and another lady, while it was driven by one of the family's drivers. On returning along the Paignton road a heavy brewer's dray ran into the car and ripped out a number of the spokes of one of the wheels, so that it was impossible to proceed. The ladies were only slightly shaken, and were able to proceed home by train.

That 7s. 6d. Motor-Car.

THE story of Mr. Martin Rucker having sold his burnt motor-car for three half-crowns proves to be one of the many comicalities emanating at the cyclists' camp at Harrogate. It is quite true that Mr. Rucker did hold a mock auction over the remains of his car, and although a magnificent offer of 7s. 6d. was made, the reserve price was not reached, and the car has, we learn, since been sent to Coventry to see if a repair can be effected.

A Tricycle Somersault.

QUITE a crop of motor accidents are reported from Ireland; but fortunately none of them have ended with serious consequences, to the riders at least. The Hon. Leopold Canning, who claims to have the fastest motor trike in Ireland, had a nasty upset on the road near Coleraine, his tricycle turning right over and pinning him underneath. He had to be rescued from his position by some wayfarer, and luckily was found to be uninjured beyond a few bruises and a severe shaking. It is surmised that he took a corner at too big a pace, and, expert motorist as he is, was unable to save himself.

Novice Accidents.

THE other accidents are in the novice class, and we think may be attributed to the dangerous custom of attempting to motor without sufficient practical knowledge. A clergyman in one case undertook to drive his De Dion voiturette after a few hours' coaching. He was spinning along at a rapid pace when a cyclist suddenly cut across the road. It was the first emergency in which the reverend gentleman had been involved, and consequently he had not that instantaneousness of action which is essential to the motorist. The car crashed into the cyclist broadside, and then the whole mix up went into the ditch. Marvellous to relate, the passengers were not seriously hurt; but the motor-car had its axles broken, whilst the bicycle was completely wrecked. Mr. T. Ireland, of Belfast, had another nasty experience near Bangor. A shying horse caused him to swerve his car so indiscreetly that it turned right over, shedding the occupants precipitately. Once again good fortune prevented any serious bodily mishap.

The Old Order Changeth.

It is indeed pleasant to hear that folks this year, instead of, as hitherto, scampering off to the Continent intend spending their holidays within our own country, for it is only just recently that the beauties of Great Britain are beginning to be appreciated. In the past the tourist has had good reason and cause to put up with the inconveniences of a journey across the Channel rather than the inferior accommodation grudgingly found and bestowed in this country. Now much has been changed. Branch lines of railways and palatial hotels have been opened up not only all round the coast but in many inland places. The best and most modern Continental hotels have not only been copied in this country but improved upon, and the management of many of these modern caravansaries has been placed in the hands of men with names which attract the traveller. In touring we have usually found it best to stay at the latest and most up-to-date hotels. The old-fashioned hotels, as a rule, we have found often rely upon a past reputation, when the proprietor could charge according to what he considered the length of a customer's purse. They had, perhaps, their advantages, for some people like to be known by their name, and object to be just a number, and nothing more, in an hotel. But, still, entering one of these old-fashioned hotels, a guest is naturally a trifle upset by observing the following notice conspicuously displayed in the hall (copied verbatim):—

"Visitors to the Hotel are expected to conform to such regulations as the manager may find it necessary from time to time to make for the general comfort of those staying in the House."

'Any person who interferes with the comforts of other guests, or with the proper management of the Hotel, may be required to leave.'

'Visitors moving at night about the Hotel are reminded that others, possibly invalids, may have already retired, and that every care should be taken not to disturb them.'

'Visitors are requested not to smoke in any part of the Hotel other than the billiard and smoking rooms. The attendants are instructed to see that this regulation is observed.'

Such a notice chills a traveller, especially when he may have just left a modern up-to-date hotel, where the best portion of the ground floor was devoted to the lounge, where electric light was available in all the rooms, and where, in the hotel such a notice is displayed, he finds lamps in the public rooms and candles in the bedrooms, where the smoking-room is capable of holding half-a-dozen smokers, who, by the way, if they sat long would stand a good chance of being "kippered."

An Enthusiastic Chauffeur.

THE well-known Mr. Staplee Firth appears to be just as much at home—to quote an oft-used idiom—with petrol as with steam cars, for the other Sunday he successfully drove a Daimler phaeton with a large party aboard a distance of close upon 60 miles. In the morning he went out with the *mécanicien*, and after a few hints drove the car from Upper Tulse Hill round Dulwich and Herne Hill, altogether about ten miles, by way of experience. After lunch, with five aboard, Mr. Firth drove the car, via Mitcham and Sutton, to Kingston, where two additional passengers were picked up. The journey was afterwards continued via Esher and the Claygate Woods to Leatherhead, where tea was partaken of. Fortunately the weather held out for the greater part of the day, but about two miles from home a very severe storm was encountered. This notwithstanding, Mr. Firth landed his party safely about 9 p.m., and he is to be congratulated on the result of his first attempt at driving a Daimler car.

A Good Run on a Werner Motor-Bicycle.

A GOOD run on a Werner motor-bicycle was made on Monday last by Mr. T. Frederick Hunt, when he journeyed from Ealing to Edgehill in Warwickshire. Leaving Ealing at 8.55 a.m., a route via Amersham, Aylesbury, Buckingham, and Banbury was followed, the destination being reached at 3.20 p.m. Deducting stoppages the net running time for the 77 miles came out at 4 hours 44 min. As Mr. Hunt only purchased the machine from the Motor Manufacturing Company, Limited, about a month ago, it is evident, in view of the successful run, that the bicycle and its rider already fully understand each other.

The 16 h.p. Napier Car.

MR. EDGE'S 16 h.p. Napier car is getting about. The other week it was in France participating in the Paris-Toulouse race, while on Monday evening last it was started on a journey to the north of England. Mr. Edge had as passengers Mr. G. H. Smith and another gentleman, and leaving town about 8 p.m. Dunstable was made for, the only stop on the journey being when darkness came on to light up the lamps. An early start was made on Tuesday morning, and Birmingham safely reached shortly after 9 a.m., the trip having been made without it being necessary for the driver or any of the passengers to dismount. We have not heard so far of the car's behaviour since Tuesday, but as it was then going strong we have no doubt its arrival in the North has created considerable interest.

Motor-Cars at Bournemouth.

FROM personal observation we find that no less than fifteen motor-cars are at present being used in the public service at Bournemouth, and are meeting with their due reward in the shape of the patronage of visitors. For some reason or other the motor-vehicles have not yet won the goodwill of all the local residents, as the police have evidently received instructions

to pay them special attention for a time. These instructions or suggestions are the outcome of a letter which the Mayor said had been received on the subject of the speed of motor-cars through Bournemouth; and, in asking Superintendent Foster to let police officers give the matter attention for a while, his Worship said that if any of the drivers of motor-cars were brought there again on a charge of furious driving they would be severely dealt with. Asked what the limit of speed was, the Mayor replied that he did not think there was any, but added that the drivers must have due regard to the traffic of the street or road along which they happened to be passing, and must regulate their speed with due regard to the safety of the public.

Motor-cars in the Eastern Counties.

To say that motor-cars are not on the increase in popularity in the eastern counties would not be in accordance with the truth. Mr. Frank Morriss, of King's Lynn, is running cars at several seaside resorts on the east coast, beside which, we noticed that two of his cars were in evidence at the Otter Hunt of the Norfolk Otter Hounds at Holme on the 1st inst.; and again the same week, at the Annual Puppy Show of the Norfolk Hounds at Barwick, near Fakenham, two cars might have been observed in the accumulation of landaus, traps, etc. Much interest and appreciation was displayed by the gentry present at the utility of the motor-vehicles, and the easy manner in which they were manipulated amongst the congregation of conveyances in the courtyard. Especial interest seems to have been evinced in the cars by the Master of the Hounds, Mr. Seymour, who as a result of his appreciation, expressed his intention of shortly joining the ranks of motorists.

Public Services in Scotland.

MR. SIMPSON, a retired farmer, who was for many years resident in the Skene and Echt district, has made arrangements to give improved facilities of communication between that district and Aberdeen, by starting a motor-car service. A preliminary run took place on Saturday last, when the car went on a trial trip from Aberdeen. The vehicle, built by Stirlings Motor-carriages, Limited, Hamilton, is designed to carry ten passengers, including the driver. The party on Saturday consisted of friends of Mr. Simpson and a representative of Messrs. Stirling. The car started from the city at 10.45 a.m. and reached the scene of the cattle show at Cluny at 12.15. In the afternoon the party proceeded over the hills to Torphins, which was reached after a run of an hour and fifteen minutes, though some of the gradients were as steep as 1 in 18. After being entertained at lunch by Mr. Simpson the party journeyed to Banchory, and the run from that town into the city occupied exactly an hour and a quarter at an easy coaching pace. The motor went very smoothly over the fifty or sixty miles to which the trip extended, and not a single hitch or stoppage was experienced along the entire route.

Opposition at Cardiff.

THE question of licensing motor-cars for public service at Cardiff, recently referred to in these columns, came up again at the meeting of the town council last week, when, on the motion that the matter should be referred back to the Cabs Committee, Mr. T. Andrews said that the chief factor that influenced the committee in deciding to refuse the licences was that before long the corporation would be running electric cars on the route right to the borough boundaries, and they did not care to allow the multiplication of competing services. Mr. Fox said that the motor-cars would be run for the benefit of a large number of people who opposed the extension of the borough boundaries, besides which they would be, if they granted the licences, creating another factor of opposition in case of further extensions and operations proposed by the corporation. Mr. A. M. Ingledew urged that the principle of the necessity of a service on the route was admitted by the existence of an inferior service, and also by the fact

that the corporation proposed to extend the tramways in the Whitechurch direction. If they persisted in refusing to grant the licences they might find the company applying for a mandamus. He was convinced that there was a necessity for a proper, regular, and clean service on the route. Mr. R. Hughes appealed to the council to grant the licences in the interests of the people of the districts affected, but after further discussion the council rejected the amendment. There seems to be some inconsistency about the position, for, at the recent meeting of the Cabs Committee, the refusal to grant the licences was based on the grounds that the road was not in a fit state for such traffic; while now the reason advanced is that ere long the corporation will be running its own electric tramway along the projected route, and are not anxious for competition on the part of motor-cars.

A Lady Automobilist.

IN our issue of July 28th last we published an illustration of Mr. F. H. Butler's 6 h.p. Panhard car, with Miss Vera Butler at the helm. Since then Miss Butler has earned the distinction of being the first English lady to drive a motor-car from London to Paris and back. Mr. and Miss Butler went over to France to see the finish of the Paris-Toulouse race, the return to England taking place last week. The journey between Paris and Havre, 140 miles, was accomplished easily in

TWO JUVENILE AUTOMOBILISTS—THE TWO SONS OF DR. FARROW, OF CLECKHEATON, ON A MARSHALL CAR.

the day, and also the journey between Southampton and London in the same time. The certificate for driving an automobile, which is compulsory in France, was obtained at Havre, after passing the necessary examination before the Comptroller des Mines.

The Roads in Surrey.

SURREY is such a popular county with automobilists that it is satisfactory to find that in its surveyor they have an official who is fully alive to the maintenance of the roads in good condition. From his annual report for the year ending with March last we learn that those roads which lie in the north-eastern part of the county are in a less satisfactory condition than formerly, but this, the surveyor states, is owing to the increase of traffic and the consequent necessity of substituting a tougher material for the flints hitherto used. He considers that "while the surface of a flint road, if properly looked after, continues to improve for some time after metalling, the surface of a granite road becomes uneven, and deteriorates steadily from the day the steam roller leaves it. Unfortunately it was impossible to keep the roads near London repaired with flints, as the material

broke up under continuous and heavy traffic, and the tougher metal, notwithstanding its attendant disadvantages, must be used." He hopes, however, to be able to improve somewhat the surface of those roads in future by using granite of a smaller gauge, which, although not suitable at first in the conversion of a flint road, may be used for recoating when the large granite has formed a crust of sufficient thickness. Another point touched upon in the report is the prejudicial effect of heavy watering upon roads. He has called the attention of district surveyors to the fact that sprinkling a macadamised road slightly with water lays the dust as effectually as flooding, and does not damage the road nor make the surface dangerously slippery.

An Unprovoked Assault.

THAT the punishment hardly fits the crime will, we feel sure, be the comment of all automobilists who read the assault case reported on another page. Mr. R. Tweedy Smith had put his car up at a stable at Putney, and on returning for it he was attacked by two drunken stablemen, and subjected to various fistic indignities, with a running commentary of highly-coloured language on the iniquities of motor-cars and their owners, and the advice to "get a respectable horse and cart." Mr. Smith got off with a black eye, a cut cheek, and many bruises. The two men were brought up at the South-Western police-court, and although the magistrate described the case as an "absolutely unprovoked assault," they were let off with a fine of twenty shillings and two shillings costs each. As one of the dailies remarked, this is cheap enough to make the baiting of automobilists a popular amusement.

An Endurance Test in America.

A £200 cup has been offered for an automobile contest to be held in connection with the tests of the Automobile Club of America in November next. The contest is one of endurance, the cup going to the car which makes the fewest stops in a run of 600 miles. There is no time limit, and the competing machines may run at any speed desired. The course will be from New York to Hudson and return, a distance of 200 miles, and will be covered three times. Only machines of American manufacture will be eligible for the contest. The donor of the cup does not desire to have his name published. If the winner of the contest so desires, £200 in money will be substituted for the cup. The tests, of which this contest will be one of the principal events, are, says the *Horseless Age*, to be held in the open air; if permission can be obtained from the city authorities, on one of the avenues or drives in the upper part of the city, possibly Riverside Drive, at Grant's Tomb. The trials embrace contests displaying the control of the driver over his machine. For this purpose lay figures of horses and men are to be set up in the street, and the machines manœuvred up and down among them, the skill of the driver in avoiding the various obstructions being shown. Backing the vehicles up and down steep grades, and stopping them suddenly when going at full speed, are other tests developing the mobility and control of the machines. The trials will be held either the week previous to or immediately following the eight-day exhibition, to be held in Madison Square Garden, New York, commencing on November 30th.

A West London Prosecution.

AUTOMOBILISTS will notice with regret the result of the furious driving case brought before Mr. Lane, Q.C., at the West London Police Court last week, especially having regard to the fact that the attempted prosecution of the Hon. C. S. Rolls and Mr. E. Hutton, J.P., were unsuccessful in this court, as was the recent prosecution against Captain Langrishe. It seems to us from the evidence in this case that there ought not to have been a conviction. The police-constable swore that the rate was seventeen miles per hour, while the driver of the car, who was certainly more capable of judging the speed of his

vehicle than the policeman, put it down as seven miles. Why the police-constable's mere guess-work as to speed should be taken for gospel we cannot understand; it looks as if this supposititious statement as to speed was accepted without being carefully challenged. For our own part we should be delighted to come across a policeman who can ride a bicycle at a speed anywhere near seventeen miles per hour on the highway.

The British Association.

FOR the second time, after a lapse of twenty-seven years, the British Association will meet in Bradford in the beginning of September. In connection with the meeting there are two papers to be read in section G. (Mechanical Science) of interest to automobilists. One is by Mr. J. G. W. Aldridge, entitled "The Automobile for Electric Street Trac-tion." It is hoped that the cinematograph will be used—for the first time, it is believed, at a British Association meeting—to illustrate this paper. The second is by Professor Hele-Shaw, of Liverpool, on "Resistance on Roads." In this paper the Professor proposes to collect together all the known data on frictional resistance on common roads, and will, it is believed, strongly advocate the appointment of a committee of the Association to carry on some further experiments on rolling friction on common roads.

Trips at Eastbourne.

ELSEWHERE along the south coast something in this direction is being done, and notably at Eastbourne the provision of trips by motor-car to places of interest is being done with enterprise and spirit by Messrs. Jury and Son, whose fleet of char-a-bancs is in frequent and daily request, taking large parties to popular resorts in the vicinity. During the day there are four trips to Meads at a return fare of 6d.; four to Pevensey Bay, return fare 2s.; one to Meads and Upperton, fare 1s.; five to Pevensey Castle, return fare 1s. 6d.; one to Polegate and Stones Cross, fare 2s.; one to Hurstmonceux Castle, fare 2s. 6d.; and on three days a week a car runs to Hailsham at a fare of 2s. 6d. Short trips around Eastbourne are arranged every evening, and even this does not exhaust the efforts of Messrs. Jury and Son to popularise the motor-car, for they let cars out on hire for the day at £2 10s.; for one hour, 8s.; for two hours, 15s.; for three hours, 21s.; and 5s. per hour afterwards.

Motor-Cars and Market Gardens.

THE idea of utilising a motor haulage in connection with the market gardens near the metropolis has been freely vented in the general and automobile press of late, and it is satisfactory to see so horticultural a journal as the *Gardeners' Magazine* giving the notion its approval. It recognises that motor vehicles would obviate some of the difficulties that market gardeners have now to encounter in getting their produce to market, and considers that it would certainly pay some enterprising carrier in Kent to make the venture. He would be certain of the traffic, and might safely rely upon his vehicle if obtained from one of the standard English makers of such vehicles for heavy traffic.

The Popularisation of the Motor-Car.

DURING the recent hot weather when horses had to take to sun-bonnets, and many fell to the pavement faint or dead, the idea of the adoption of motor-vehicles for City traffic received a great impetus. No less so did the heavy rains of the past few days influence public opinion, for the way in which horses slipped and fell was most distressing. Possibly these facts have something to do with the more general appearance of motor-vehicles in the streets. One can hardly ever go out without seeing a motor-vehicle, and such London thoroughfares as Holborn, Shaftesbury Avenue, etc., are veritable automobile promenades. These are signs that show the future popularity of motor as compared with horse traction.

The English Motor Club.

ALTHOUGH but relatively a few took part in the run of the members of the English Motor Club on Saturday last, it was none the less an enjoyable outing. There was no organised procession, the members making each their own way to the White Lion Hotel, Cobham, where, according to the programme, tea was to be served at 4.30 p.m. Mr. G. H. Smith on a De Dion trike was the first to arrive, followed quickly by Mr. C. Jarrott and Mrs. Edge on a De Dion voiturette. The next to run into the hotel yard was Mr. Roger Fuller on his De Dion voiturette, and almost on his heels appeared

From Cobham to Frensham.

It was not till about 6.30 p.m. that a restart was made, when the number continuing the run to Frensham was somewhat curtailed. Those who set out for the latter place included Messrs. Edge and Napier on the 16 h.p. Napier; Mr. Jarrott and Mrs. Edge on the De Dion voiturette, Mr. Baily on his trike, two gentlemen on the quad, and Mr. Fuller on his De Dion voiturette. The latter gentleman, however, only went part of the way, having, like ourselves and several others, to return home the same evening. Mr. Jarrott has since informed us that Frensham was duly reached, the little party staying

MESSRS. ADAMS AND BILLINGS ARRIVE ON THE CANELLO-DURKOPP CAR.

DR. HARDWICKE, OF MOLESEY, ARRIVES ON HIS BENZ CAR.

IN THE YARD AT THE WHITE LION HOTEL, COBHAM.

MESSRS. EDGE AND NAPIER DEPART FOR FRENSHAM ON THE 16 H.P. NAPIER.

THE ENGLISH MOTOR CLUB'S RUN—SNAPSHOTS AT COBHAM.

the 16 h.p. Napier with Messrs. Edge, Napier, and Dangerfield aboard. Two gentlemen on a quadricycle, and Mr. F. W. Baily on a tricycle, next arrived, and after a short interval Messrs. Adams and Billings turned up on one of the new 8 h.p. Canello-Durkopp cars, which came in for a close inspection. Dr. Hardwicke and Mr. Fletcher (both of Molesey), the former on his Benz and the latter on a Mors car, also ran over to Cobham, just to pass the time of day, as it were. After a pleasant ramble through the grounds of the old hostelry the little party of thirteen sat down to tea, and although the number is supposed to be an unlucky one a very pleasant hour was spent.

there until Sunday afternoon, when the cars' noses were once more turned townwards, the White Lion at Cobham being again the stopping place for tea. Elsewhere in this issue we reproduce a few snapshots taken at Cobham.

MESSRS. A. DAVIS AND CO., cycle makers and engineers, whose premises adjoin Tooting Junction Station, inform us they undertake repairs of all kinds. They also keep a supply of motor-car spirit in stock.

PRACTICAL HINTS ON MOTORING.*

MY experience up to date with automobiling is that the greatest trouble confronting the makers and sellers of automobiles is to convince people that the motor-vehicle of to-day is a carriage with an engine or motor in it, and that it is a piece of machinery that needs oiling and attention. An engineer oils his engine every morning and noon and frequently between times, knowing full well that without lubrication the engine will not run correctly. When we get operators of automobiles to thoroughly understand that a motor-car is an engine or motor placed in a carriage, and that it must be lubricated and attended to as such, then we will hear few complaints about the thing, as they call it, being out of order.

A successful operator of automobiles knows full well that by tightening up a nut, when it becomes loose, he is saving time and trouble in the future. If the owner or operator cannot master the lubricator or adjustment of his carriage he should take it regularly twice a month to an experienced and competent person, who does understand the mechanism and have this attended to by him. To do this means a great saving in the expense of repairs.

Many people say to me, why must I do this, why don't you build a machine which does not require any attention? I tell them frankly that such a thing is impossible. You eat, but you soon get hungry again, because the laws of nature demand that the subsistence on which we exist shall be replenished very often; it is just so with the automobile, it must be lubricated and attended to every day, and when run all day should be lubricated twice a day. I have found on long runs of 75 or 100 miles that it pays to stop every 20 or 25 miles to look over the motive power and see that all is working correctly. Sometimes a nut would work loose or some part of the machine was not oiling properly. These defects when looked after always saved me from breakdowns and serious and unpleasant delays.

In repairing automobiles of all makes, styles, and sizes a thoroughly practical knowledge of steam and petrol engines is absolutely necessary, without which you will find that you have a much greater problem on your hands than you bargained for. Very frequently the owner of an automobile will get a good machinist to take his engine apart, and when it comes to putting it together again and starting it up, it refuses to go. This is due to the fact that some part is not put back exactly in the right position. This trouble occurs more in hydro-carbon or petrol engines than in steam engines, but very frequently we find it in steam engines, too. The proper method is to get your car overhauled by persons who have made a special study of automobile mechanisms, and who have had experience in that line.

In hydro-carbon engines, the most serious troubles are due to the sparking points becoming coated or corroded so that the engine will miss explosions. These should be dressed slightly about once a month or at least every six weeks, taking care that oil does not get on the wires so as to form a short circuit outside of the cylinder and thereby prevent the charge from igniting. Considerable trouble has been encountered from piston packing rings being cut aslant. As soon as the rings are worn just a little the compression is allowed to escape around the pin and through the slot and the engine in consequence loses a great deal of its power. I consider a better plan for petrol engine packing rings is to make the ends overlap one another. In a half-inch wide ring have the ends dressed to $\frac{1}{4}$ inch right and left and overlap, then as the rings wear you do not lose compression as in other forms.

In transmitting power from the engine to the running gear of the carriage I fully believe that the use of a friction clutch is advisable, although some are using a positive or gear clutch, in which gears are made to shift from one wheel to another, frequently, however, breaking off the teeth and doing a great deal of damage to the working mechanism. By using a friction clutch, the breaking of gear teeth is avoided and a more even transmission is secured. The clutches need setting up frequently to prevent slipping of parts and consequent grinding.

* By W. F. R., in the *Chicago Automobile Review*.

That which appears most strange is that one operator may take a certain carriage and run it for hundreds of miles without the slightest mishap and another operator takes the same car and runs it only a few miles and smashes something on it. As an illustration I may take as a case in point the following: A certain carriage was run one week by a customer and pronounced worthless because something broke on it nearly every day. The same carriage was given to another customer, who has operated it two months without the slightest mishap to the carriage. Why is this? Is it the machine or is it the operator? An operator should become as familiar with his machine as possible, so that he may know by the sound whether everything is working right or not. He should always remember that he is operating a machine, which, when properly cared for, will afford him more pleasure than anything I know of, but in order to secure the satisfaction of successful running, the little wants of the mechanism must be attended to and everything maintained in first-class condition.

THE LEPAPE PETROL CAR.

M. H. LEPAPE, of Puteaux (Seine), France, whose connection with automobiles extends over the last ten years, has kindly sent us the accompanying illustration, together with some particulars of his latest type of car. In doing so he remarks that his main object has been to simplify and to diminish as much as possible the number of organs which

FIG. 1.—SECTION OF LEPAPE CARBURETTOR.

go to form a modern motor-car, and adds that the vehicle which we are about to describe is the result of protracted experiments both with the various parts and with complete vehicles. As will be seen from the illustration, the lines of the car are quite new. The frame is built up of steel tubing joined together by forged lugs. The axles, which run on ball bearings, are connected to the frame by special springs, which are claimed to prevent the transmission of jolts, due to uneven roads, to the motor and transmission gear. As will be observed, the body is entirely independent of the frame, on which it is suspended fore and aft by C-springs. It is described as being exceedingly comfortable and free from vibration.

The engine is located under a bonnet in the fore part of the frame. It is of the vertical single-cylinder type, and at 750 revolutions per minute is said to develop 5 h.p., the diameter of the cylinder being 100 mm. and the stroke 120 mm. Electrical ignition is adopted, the feature of the motor lying in the fact that it is air-cooled, and this without the use of radial fins to the cylinder walls. Unfortunately M. Lepape has not thought well to send us full particulars of the special means he adopts to cool the

cylinder, but from another source we learn that the cylinder and combustion chamber are cast in one piece, and are of such a thickness that the heat generated cannot, it is claimed, heat the great mass of metal to above a temperature of 200 deg. C. The hot air in the bonnet is also dissipated by means of a small fan driven off the motor shaft. The valves may be quickly taken out by the removal of a single plug; the exhaust valve is made of ferro-nickel. The sparking plug is of large size; it also can quickly be withdrawn and all its parts are detachable, none of the joints being made by cement or solder. Special attention has been paid to the lubrication of the working parts of the engine, the flow of oil increasing with the speed and only taking place when the engine is running. The carburettor adopted is of the type which has already been described in these columns (see Vol. I., p. 570). Fig. 1 gives a sectional view of the device, which is claimed to be unaffected by vibration or by any difference of level of the petrol in the storage tank.

The power of the motor is transmitted by belts to the intermediary shaft, and by one set only of sprocket wheels and chain from the latter to the rear axle. No differential gear of the usual type is employed, M. Lepape having adopted a special device by means of which, while not overcoming side-skidding, he claims to obviate all chance of a right-about-turn skid. Three speeds forward and a reverse motion are provided, the belts working on fast and loose pulleys, the belt-shipping forks being controlled by a system of cams. The forks are mounted on bars terminating in a roller, the bars being made to bear by a spring on circular cams of a special form. The four bars run in slides, which divert them on to their respective cams, the latter being mounted on the end of a vertical shaft, on the upper end of which is the controlling hand wheel. The device is so arranged that none of the belts can be put on the fast pulleys except the others are on the loose ones. The three speeds forward—8, 16, and 30 kilometres per hour—and reverse motion are all obtained by the rotation of the hand-wheel through one revolution, that is to say, it is only necessary to move the wheel through a quarter of a revolution to change from one speed to the other. A bronze gearcase protects the cams from water and dirt. Inside the variable-gear control standard is mounted the steering column, on the upper end of which is a horizontal hand-wheel. The steering is of the irreversible type. On the outside of this standard are mounted three taps or handles, one connected with the variable ignition, one regulating the quantity of air allowed to pass into the carburettor, and one controlling the volume of carburetted air allowed to pass to the explosion chamber of the motor.

The wheels are of the cycle type, shod with pneumatic tires. A hand-lever operates shoe brakes on the latter, while a band brake operated by a foot pedal is also provided. This pedal is so arranged that on being pressed by the foot the belts are first shipped on to the loose pulleys, continued pressure applying the brakes. The car has accommodation for two or three persons, a folding seat being provided at the front.

THE LATE M. E. LENOIR.

THE death is announced of M. Etienne Lenoir, the pioneer of automobilism, who passed away last week in his seventy-eighth year. As far back as 1860 M. Lenoir took out his patent for a gas engine, and two years later his first car was built, and for some time was to be seen in the neighbourhood of Paris. He, however, left the automobile at this stage, and confined his attention to automobile boats. Since then very little was heard of M. Lenoir until quite recently, when, at the instance of the Automobile Club de France, a commission was appointed to discover the real inventor of the petrol automobile. As the result of diligent inquiries, the palm went to M. Lenoir, and in recognition of his services the A.C.F. presented him with a gold medal.

THE Motor Manufacturing Company, Limited, write us with reference to the question as to whether an advertiser who states he can supply 4 h.p. De Dion voiturettes has not made an error. They consider that no error has been made, as they are manufacturing a 4½ h.p. De Dion water-cooled motor.

A PARAGRAPH has lately gone the rounds of the Press to the effect that the Potteries Electric Tramways Company is about to introduce automobile cars to connect as near as possible their different terminuses. We are in a position to state that no decision has as yet been arrived at in the matter.

The men employed at the Ivel Motor-car Works, Biggleswade, Beds., were given a dinner last Saturday by Mr. Bateman Brown, of Huntingdon, who some few months back had an Ivel car made to special requirements. The car has turned out so satisfactory that Mr. Brown entertained the men at

the Ivel Hotel, taking the chair himself. Mr. Bateman Brown, who is seventy-nine years of age, is quite a motor enthusiast.

THE Sports Motor-Car Company, of South Kensington, S.W., have sent us a copy of the new price list they have just issued. In addition to particulars and clear illustrations of the Mayfair voiturette recently illustrated in these columns a number of pages are devoted to a new series of 6 and 8 h.p. cars—dogcarts, brakes, wagonettes, phaetons, etc.—which are being introduced into this country under the name "Sports."

COUNT CHARLES SEILERN, who was recently elected a member of the Automobile Club, has just received delivery of a 12 h.p. Panhard car. The vehicle, which takes the form of a four-seated wagonette, has an attractive appearance, it being painted a French grey. The motor is provided with double ignition—both tube and electric. The car was safely brought to town from Folkestone on Tuesday, and has since been taken down to Crawley.

THE Speedwell Motor Company, of Reading, inform us that they are now fixed up in their more central premises at 134, Broad Street, Reading, and are recovering from the effects of their late disastrous fire, mention of which was made in these columns a few weeks back.

FIG. 2.—GENERAL VIEW OF LEPAPE CAR.

MOTOR-WAGONS FOR MUNICIPAL PURPOSES.

IN a recent issue the *Municipal Journal* criticised at length the results of the trial with a steam-motor dust van by the Chiswick District Council. In the article in question attention was drawn to the excessive cost of collection by means of this vehicle, as compared with horse-drawn vans and carts. Mr. Reuben J. Cook, a member of the Chiswick District Council, now writes to our contemporary with reference to the criticisms, as follows:

"I have read with interest the article on motor-vans for dust collection, and think that, as a member of the Chiswick

FIG. 1. GENERAL VIEW OF AMÉDÉE BOLLÉE AMBULANCE CAR.

Council, the following remarks upon this subject may be of interest to your readers:—Owing to certain reports, the Council resolved to obtain a return in full of the work done by steam dust carts and by horse-vans during a fixed period of twelve months, and this return was duly presented.

"From a perusal of this, it is seen that the respective costs per ton of refuse collected are: By steam carts, 5.62 shillings; by horse vans, 3.96 shillings; and by horse carts, 4.18 shillings. This result, apparently, discounts the steam vehicles, but it is necessary to point out that our parish is of considerable length, and that the steam vehicles have been regularly employed in those parts of our district most remote from the tip. The time available for actual refuse collection has thus been considerably reduced on account of the length of time occupied in going to, and returning from, the tip. It is somewhat noteworthy that the cost of actually collecting each ton is exactly the same as that in the districts close to, or even adjoining, the tip, showing clearly that there must be a considerable gain to the parish when the vehicles provided for this work can make a journey to and from the tip and collect refuse at no greater cost. This point was fully recognised at a recent discussion, and it was further resolved that, in order to a better estimate of cost, the steam carts should during a period of six months serve the areas nearer the tip, the horse-vans taking the more remote portions of the district. At the expiration of this period, it will be interesting to note the cost-figures obtained.

"In the matter of repairs, it is equally misleading to have any opinion, favourable or otherwise, to the steam vehicles, for the reason that the price quoted by the builders in their tender was £350, whereas actual experience has shown that their price is just double this amount. Taking, however, the initial cost at

£350 each, and £95 odd for repairs, this is not at all excessive, for it must be stated in fairness to the builders that their guarantee was for a load of three tons, whereas it is an open secret that on many occasions these vehicles have been employed in removing slush from the high road. This is extremely heavy stuff, and the carts have in this way often carried a load of six tons at a time without any difficulty.

"Again, the site and surroundings of the tip must be understood in order to arrive at a true opinion on the value of these steam cars. There is an area of some three or four acres, and as the refuse is deposited, a rough timber road is laid thereon, and it has been no unusual thing to see the steam waggons buried up to their axles, though they are able always to easily free themselves. In my opinion, if only for this purpose, the steam vehicles have served their object admirably, as, had it been attempted to fill this tip from horse-drawn vans or carts, a spare horse and man would have necessarily been in attendance constantly, and, allowing the cost of this item at 7s. daily, would have resulted in a marked saving being shown in favour of the steam cars. In conclusion, I would point out that the steam vehicles have proved a very great acquisition to the parish, as, until they were obtained, the contractors were absolutely masters of the situation. Further, the steam cars were of great service in settling the maximum load that should be drawn by horses, and the information thus gained was utilised in the design of the two-horse vans."

MOTOR-CARS IN THE FRENCH ARMY.

ON many occasions reference has been made in these columns to the great service which motor-cars and wagons are likely to render in future military operations. It has been our object to, as far as possible, put on record everything that is being done abroad in this

FIGS. 2. AND 3.—SECTIONAL ELEVATION AND PLAN OF AMÉDÉE BOLLÉE AMBULANCE CAR.

direction, with the view of drawing the attention of our own military authorities to the possibilities of motor-vehicles. On

the present occasion we propose to deal with some of the automobiles displayed by the French Government in the Palais des Armées at the Paris Exhibition. The ten cars exhibited form quite an interesting collection, including as they do a Scotte steam tractor, a De Dion steam tractor, a Panhard omnibus, a Decauville voiturette for the use of the état-majors, a postal and telegraphic car by the Mors Company, a fast Mors car for the use of état-majors, a travelling office car for the use of the General Commandant by the Peugeot Company, a postal car by the Georges Richard Company, an ambulance van by the De Dietrich Company, and a telegraph service wagon by the Koch Company.

FIG. 4. THE GEORGES-RICHARD MILITARY POSTAL VAN.

Of the three last-named vehicles we are herewith enabled by the courtesy of our French contemporary *Le Chauffeur* to give illustrations. As the motor and mechanical portions of all these vehicles are of the standard type and have already been described in these columns it is unnecessary to refer to them on the present occasion. Fig. 1 gives a view of the ambulance van; this is on the well-known Amédée Bollée system, the frame having been built by Messrs. De Dietrich and Co., of Luneville, and the carriage work by Messrs. Kellner and Fils, of Paris. Figs. 2 and 3 give sectional views of the car, which has been adapted to receive the standard fittings of the

FIG. 5. SECTIONAL ELEVATION OF GEORGES-RICHARD MILITARY POSTAL VAN.

Service de Santé. In front is a seat with accommodation for the driver and two other persons. This seat forms a tank, divided into three compartments, *I*, *G*, *J*. The compartment at the right, *I*, contains the water for cooling the engine, that in the middle is reserved for lubricating and lamp oil, while *J* is the petrol compartment. Formed in the dash-board are three other small compartments; those at the sides, *L*, *M*, are reserved for

the driver's tools, while in the central one is located a small stove. Below these compartments space is left to store a lifting-jack. The partition *AA'*, which forms the back to the driver's seat, is movable, and gives access to a compartment *N*, in which is stored an operating table and several collapsible buckets. Behind the compartment *N* is built a framework adapted to receive twelve paniers, six on each side, each containing the regulation equipment of surgical appliances, etc. Sliding doors on each side give ready access to these compartments. Additional storage capacity is provided in the compartment *F*, which is divided into two portions. At the rear seating accommodation for two surgeons is provided. The entrance is at the back of the car. The compartment is provided with a folding table, a lamp, and four hooks for supporting clothing, swords, etc. The seats in this compartment also form water tanks, *E*, each having a capacity of 25 litres. To the outside of the rear of the van is attached a sterilising apparatus *D*, while there is also carried at the back a special collapsible tent. An iron ladder gives access to the roof of the van, on which further stores in the way of litters, etc., can be carried. The car, which is mounted on solid tired wheels, is fitted with a 9 h.p. motor; four speeds, 4, 8, 12, and 16 kilomètres per hour are available. The body is painted the regulation grey colour; the car, without stores and supplies, weighs, it is stated, 1 ton 5½ cwt.

Figs. 4 and 5 show the military postal van built by the Georges Richard Company. The mechanism of this vehicle is

FIG. 6. THE KOCH TELEGRAPH SERVICE WAGON.

similar to the Richard cars which took part in the recent 1,000-Mile Trial in this country. The engine is of 7 h.p. and four speeds—7, 14, 21, and 28 kilomètres per hour—are available. The body, which is painted the regulation green colour, takes the form of a large chest, to receive letters and parcels, and access is afforded to the chest by the lid *A* and by the small door, *B*. A compartment *C* is formed in the body by means of which the driver has access to the transmission gear. The volume of the chest is 980 litres—much greater than is possible with the horse-drawn postal vans.

In Fig. 6 we see the telegraph service wagon built by the Koch Company, and Messrs. Sautter, Harlé, and Co., of Paris. It is equipped with an 8 h.p. heavy-oil motor, and has two speeds—5 and 16 kilomètres per hour. The car is an exact reproduction of the horse-drawn vehicle used for the same purpose except at the front, where the motor is located. A special steering gear was necessary in order to control the car from the perched-up seat, which is a relic of the horse-drawn wagon. Empty the motor-vehicle weighs 1 ton 9½ cwt. The body is painted grey, while the wooden wheels are shod with iron tires.

The Mors travelling telegraphic office referred to above is fitted with an 8 h.p. motor, and has four speeds, ranging from 8 to 32 kilomètres per hour. The front seat has accommodation for two persons; inside is carried all the necessary apparatus for carrying on telegraphic communication, while at the rear is a compartment for two additional persons.

PARIS EXHIBITION NOTES.

(FROM OUR OWN CORRESPONDENT.)

(Continued from page 393.)

AMONG the provincial constructors of automobiles who are exhibiting one of the best known is M. Ripert, of Marseilles. This maker shows a single car, a four-seated phaeton, provided with a two-cylinder horizontal motor, developing 12 h.p. This engine is placed in the fore part of the vehicle, and is readily accessible in case of need. Tube has been given the preference over electric ignition, but from their position I should not be surprised to learn that the burners occasionally give trouble. The circulation of the cooling water is effected by a friction pump. A single leather belt serves to transmit the propulsive effort, while cog gearing is used for the different speeds. There are four of these latter, varying from four to thirty-five miles per hour, and they are actuated by means of a lever which is placed upon an upright in front of the driver, which also serves as a support for the inclined wheel steering. This upright also carries an accelerator which operates upon the centrifugal governor.

A lever at the right of the conductor actuates the forward and reverse gear. A couple of pedals serve to partially or wholly disconnect the motor by releasing the tension of the driving belt, and to brake the car. A hand brake acting upon a band attached to the sprocket wheels is also fitted, and a ratchet and cogwheel upon the cross shaft are used to prevent the danger of the car running back. A large awning carried by a single support provides protection for the passengers from the sun. M. Ripert also constructs vehicles of 7 and of 9 h.p.

The productions of MM. Bouquet, Garcin, and Schivre have long been considered by competent judges as the best electrical cars constructed in France, and this year they have come prominently before the notice of the public by reason of the wonderful record made on May 12th last. Upon that day a B.G.S. vehicle, as they are commonly called, was driven 262 kilometres, or some 164 miles, without recharging, so beating by 110 kilometres the previous best performance on record. Naturally the ordinary B.G.S. car is not capable of doing a like feat, for the record holder is a specially constructed vehicle and carries 1,260 kilos of batteries, its total weight being 2,300 kilos. But then the ordinary electromobile is never called upon to attempt voyages of this kind, and the current type of B.G.S. is proportionately quite as good and capable a vehicle as the racer. The firm exhibit at Champ de Mars a pretty two-seated car and a motor and frame, the former being fitted with "Kelly" and the latter with "Compound" tires. An inspection of the chassis at once reveals its extreme simplicity. The mechanical organs of the car really resolve themselves into an intermediary shaft carrying a set of driving gears, and all the parts can be readily and quickly taken down should occasion demand. One motor only is carried, for when one diminishes the size of an electric engine the yield decreases very rapidly, and

the constructors of the B.G.S. are strong advocates of the employment of a single motor of high production. This motor is carried in the fore part of the frame and is hermetically encased in a steel box. At the right of the driver and let into a well below the level of the seat is a small wheel by means of which the vehicle is entirely controlled. No less than six forward and two reverse speeds are provided, while a couple of electric brakes for the forward and a similar number for the backward motion are fitted. The steering is effected by means of an inclined wheel, and an additional pedal brake on the Renault double-action system is attached. In order to charge the batteries a current of at least 100 volts is necessary, and as the accumulators can be instantly detached from the car, the operation can be carried out with equal readiness whether the batteries are in place or not. Moreover if the batteries be fully charged the vehicle may remain unused two or three weeks without an appreciable loss of current. Other objects of interest on the B.G.S. stand are photographs of the big racing car and of the wagon in use by the fire brigade of Paris. This latter vehicle was built in the works of the fire brigade, but engine and accumulators are of B.G.S. construction. It weighs 2,600 kilo-

grammes and carries 520 kilogrammes of batteries. On ordinary roads it has a range of sixty kilometres, and since April last has been in daily use by the brigade.

M. Dupressoir, of Maubeuge (Nord), shows an excellently designed and constructed voiturette frame, carrying a 3 h.p. water-cooled De Dion motor. This voiturette is known as the "Rolling." It is fitted with three speeds and reverse motion, the intermediary speeds being secured by means of a friction clutch. Upon the pillar carrying the steering wheel are to be found the small levers necessary for the regulation of the air and

GENERAL VIEW OF THE BRULÉ-PONSARD MOTOR-CAR. (See opposite page.)

ignition, and above these is placed the speed change gear. A couple of pedals for the manipulation of the friction clutch and brakes complete the list of controlling parts. A very nicely turned out quadricycle frame and a number of differential shafts, gears, wheels, etc., go up to make a thoroughly interesting exhibition. All the parts are beautifully finished, and quite worthy of the reputation which M. Dupressoir holds.

A taking voiturette is exhibited by MM. Hanzer Frères, Petit-Ivry (Seine), the motive power being supplied by a 3 h.p. water-cooled De Dion motor. It is mounted on wheels of equal size (700 by 80) and weighs 340 kilogrammes. Three forward and one reverse speeds are fitted, and the steering is effected by an inclined wheel. This firm also show a tricycle furnished with a De Dion motor, and of neat and workmanlike construction.

A taking little vehicle is shown by M. Deschamps, of Rue St. Augustin, Paris, whose stand will be found next to that occupied by the Scotte trains. The car is known as the "Excelsior," and it is fitted with a two-cylinder petrol motor, developing 4 h.p. This engine is carried in front of the car; it is air-cooled, and its two cylinders are set at an angle of 90deg. A small lever actuates the speeds, of which there are three, and the steering pillar itself is utilised to throw the motor in or out of gear, as may be desired. When placed forward this pillar connects

motor and gear; when drawn back it disconnects. Running at all fast over bumpy ground, I fancy that to maintain the desired position of the pillar would be no easy matter, and that one would be continually cutting off the power. The usual levers for the regulation of carburation and ignition are provided. The total weight of the voiturette is 180 kilogrammes.

Another small car is that exhibited by M. Louis Guerraz, of Paris, the feature of which is the suspension of the body by means of C springs in such a manner as to render it remarkably free from the vibration conveyed to the frame by the motor. The "Aster" 5 h.p. water-cooled motor is employed, and is carried in front of the car. Three changes of speed permit the car to run at from five to thirty-five kilometres per hour. The vehicle weighs 250 kilogrammes.

The display made by MM. E. Delahaye & Co. is as excellent as it is varied. The disposition of the motor and frame as constructed by this firm lends itself particularly readily to the carriage-builder's art, and the result is shown by the stylish appearance of the cars exhibited. I have often wondered why MM. Delahaye place that box of lubricators at the back of so many, if not all, of their cars. To my idea the driver should have everything before his eyes, and should be able to tell at a glance whether his engine is receiving all the necessary attention in the matter of water, lubrication, etc. There should be no necessity to descend from his seat and inspect lubricators, etc., placed at the back of the vehicle. Let everything be visible from the driver's seat. To begin with the smallest of Delahayes' exhibits, there is the voiturette carrying a $4\frac{1}{2}$ h.p. single-cylinder horizontal engine. Except its habit of showing steam very quickly this little car is really excellent, for not only is it smart in appearance, but it is well and strongly made, and its mechanism is reduced to simplicity itself. All the other cars shown are fitted with either 7, or $9\frac{1}{2}$ h.p. motors, and they are: First, a four-seated wagonette or "tonneau," tastefully painted with yellow as the predominating colour. Then a big six-seated car fitted with a canopy. Access to the middle seat is by the side, while a door at the rear permits of entry to the back seats. Another "tonneau" and a covered-in wagonette complete the list, and the carriage-builder in particular should make a point of inspecting MM. Delahaye's collection.

An imitation of the Renault car is shown by M. Baudier, of Neuilly, Paris. The type exhibited is the "Spider"—that is to say, it has two seats in front and a light detachable seat behind. The frame is built up of steel tubes and carries in front a 3 h.p. water-cooled De Dion, the water circulation being secured by means of a friction pump. A radiator is fitted underneath the fore part of the car. The De Dion carburettor is used, and wheel-steering is usually fitted. The transmission is direct by means of a friction clutch, and three forward and one reverse speeds are obtained by a special gear, the wheels of which are always engaged. A contact button placed on the steering gear enables the electric current to be cut off when desired, and the car is certainly one of the neatest of its class that I have ever seen. The price is £168 and the weight about 200 kilogrammes. M. Baudier also constructs a smaller and cheaper car fitted with the $2\frac{1}{2}$ h.p. De Dion. Weighing only 150 kilogrammes, the two speeds with which it is provided are entirely sufficient for this little car, and enable it to successfully negotiate all ordinary hills.

(To be continued.)

A PETITION by Mr. C. E. Foster and other contributories of the London Electrical Cab Company, Ltd., asking for the compulsory winding-up of the company, was before Mr. Justice Wright, sitting as an additional Judge of the Chancery Division, on the 8th inst. It was arranged that the petition should stand over.

At the Lambersart Track, Lille, on the 5th inst., an hour motor race was run off. There were eight starters, viz., Béconnais, Fossier, Demester, Vasseur, Loste, Cabailot, Bathiat, and Louis. The winner was Béconnais, with $57\frac{1}{2}$ kiloms. to his credit, his intermediate times being; 10 kiloms., 10m. 30s.; 20 kiloms., 20m. 30s.; 30 kiloms., 31m. 4s.; 40 kiloms., 41m. 45s.; and 50 kiloms. 52m. 36s. The distances of the others were: Loste, 54 kiloms. 600m.; Demester, 53 kiloms. 800m.; Cabailot, 53 kiloms. 320m.; Fossier, 53 kiloms. 200m.

THE BRULÉ-PONSARD MOTOR-CAB.

A NOVEL form of motor-cab has recently been introduced in France by Messrs. H. Brulé and Co., of Paris, the feature of the vehicle being that the whole of the motor and the power-transmitting mechanism is carried on a turn-table on the fore carriage, the front wheels thus serving for the driving and steering of the vehicle. As will be seen from the illustration the arrangement adopted forms a kind of *avant train*,

FIG. 2.—PART-SECTIONAL ELEVATION.

or what may be termed a self-propelling bogie, so contrived that it can be substituted in a very short time for the ordinary fore carriage of a horse-drawn vehicle. As shown in the sectional elevation, Fig. 2, the bogie comprises a platform *E E'* built up of angle iron, supported on the divided rotating axle *A*, driven through balance gearing from the

FIG. 3.—TRANSVERSE SECTION.

motor, which is mounted on the platform. The latter carries a ring *B*, grooved to form a ball race. To the fore part of the vehicle body is also attached with intervening supporting springs, *F*, a similar ring *C*. These two rings bear one on the other through the medium of the balls *H*. Means are of course provided for keeping the balls in their places, and preventing the rings from separating. The platform *E E'* and the lower ring *B*, which carry the motor and all the driving mechanism, are connected with the front road wheels, and move

with the same under the action of the steering gear. The motor, which is of $4\frac{1}{2}$ h.p., is also of a special character. It is known as the Rozer-Mazurier, and is a combined petroleum-spirit and hot-air engine, the exhaust gases from two of the cylinders being used to actuate the third or hot-air cylinder.

From the crank shaft *M* the power is transmitted through gear wheels to the intermediary *T* (Fig. 2). The latter carries the speed-varying gear, two forward speeds—7 and 16 kilometres per hour—and one backward motion being provided. From the intermediary to the front wheel axle the power is transmitted through the gear wheels shown in Fig. 3. A jack-in-the-box gear *D* is also provided on the front axle.

Dealing now with the steering mechanism, the platform *E E'* and the ring *B* are connected by the arched pieces *K* to the vertical tube *L* (Figs. 2 and 3). This tube, which is fixed centrally, carries on its exterior a toothed sector *N* (Fig. 2), steering being effected through the pinions *O* and *P* connecting the handle *Q* with the sector. The tube *L* also serves as a passage for all the levers controlling the motor and the transmission mechanism, brakes, etc., these levers being all grouped on a standard behind the steering handle. We learn that since this vehicle was constructed certain modifications have been decided upon. The most notable of these is that the steering pillar and the lever-supporting standard are to be combined, thus giving a more compact appearance to the controlling mechanism in front of the driver.

WE hear that steps are being taken in Newcastle-on-Tyne to form a motor-car club in the northern city.

THE Shah of Persia last week visited the most recently-equipped fire station in Paris, where he examined the automobile fire engine with interest.

THE Motor Manufacturing Company's 6 h.p. Panhard car which went through the 1,000-Mile Trial is now in Bournemouth, it having been purchased by Mr. H. Passmore.

THE Rev. A. B. Whatton, who is well-known in motor circles, has, we learn, ordered one of the new Canello-Durkopp cars from the British and Colonial Motor-Car Company, of Baker Street, W.

A COLCHESTER correspondent writes that every day heavy motor-wagons carrying all kinds of merchandise are to be seen in the streets of the town, to say nothing of automobiles speeding on their way from London to the east coast.

THE motor-car now plays an important part in the programme of country games in Aberdeenshire. At the Haddo House games last week two cars running on a circular tour were very largely in demand during the greater part of the day.

THE Star Motor Company, of Wolverhampton, ask us to mention that in the tabular statement given in their recent advertisements of the performances of the various cars in the 1,000 Mile Trial the full records of the Roots and Venables heavy-oil car were, by an oversight, omitted.

WE learn that the Sports Motor-Car Company, of 103, Fulham Road, South Kensington, S.W., are about to put on the market in this country a new car fitted with a double-cylinder engine of 6 h.p. The vehicle is fitted with three speeds forward and one reverse. The car has no belt nor chains and will it is claimed, climb up any gradient of 1 in 6 with a full load of four persons and on ordinary road average thirty-five miles per hour.

ONE of our visitors the other day was Mr. F. Sadler, of 15, Grays Inn Road, W.C., who is about to bring out a new anti-vibratory handle bar for motor-cycles. In the new arrangement the bar proper is made separate from the stem, to which it is connected by special connecting links, the vibration being taken up by two springs in a sort of small cage on the top of the stem. The arrangement adds but little weight to the bar, is not unsightly, and is claimed to greatly reduce the amount of vibration transmitted to the rider's hands. We are promised a trial of a machine fitted with the new bar.

CORRESPONDENCE.

A BLAZE AT LINCOLN.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—With reference to the paragraph referring to a slight flare-up on one of my company's cars, it may interest you to know that the incident was so trivial that, after examination at the dépôt, the car was directly after again running on the route as though nothing had happened. With pressure feed there will always remain a similar risk. A pipe fracture or a loose connection and the thing is done. The oil tank never became ignited, nor did the flames rise "to a height of several feet"! Possibly the driver's eyebrows were singed. Truly a terrible catastrophe!

Yours truly,

ALFRED W. GOODALL,
Manager the Lincoln Motor Bus and Parcel Delivery
Company, Limited.

Lincoln, August 12th, 1900.

PNEUMATIC TIRES AND PUNCTURES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR—The suggestion made by your correspondent Mr. Vanderhyl to place a piece of leather belting on the inside of a pneumatic tire is a very old idea, and has been tried by, I might almost say, many hundreds of inventors, but he will find if he tries it that there are no means of making the leather belting part and parcel of the outer cover, and if it is left loose there is an enormous amount of internal chafing set up. The simplest way to avoid the punctures your correspondent refers to is by having large diameter tyres so that the weight per square inch of surface is much reduced, and it requires very sharp puncturing instruments to go through the cover. With large pneumatic tires punctures are extremely rare.

Yours truly,

14, Regent Street, London, S.W.
August 13th, 1900.

S. F. EDGE.

QUESTIONS RE MOTOR-CYCLES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Have any of your readers devised any satisfactory method of regulating the throttle or quantity valve of motor-cycles direct from the handle grip, by revolving it or otherwise, instead of by means of the usual lever which is placed on the top tube? In driving my quadricycle there are many occasions upon which I cannot spare a hand from the handles long enough to regulate the lever with that nicety which I desire, such as when rounding corners of winding lanes, when the road slants to one side, and so on, and when the road is very rough the jolting in any case makes it difficult to place the lever in the correct position for the speed desired. In consequence I have to do a good deal of regulating under such circumstances by switching the current off and on, with resulting unpleasant jerky progression for passenger and self, the lever being placed haphazard so far open as would give me much more speed than desired if the current were kept on without intermission. I do not know what other readers think, but I am of the opinion that the ability to regulate the throttle direct from the handle grip would be one of the greatest conveniences possible in connection with driving a motor-cycle.

I should also be glad to know whether anyone has devised a satisfactory and easily worked exhaust valve opener for the Ariel motor-cycle, which does not in any way damage or overstrain any existing part of the machine. I arranged and fitted up an opener some time since, but I found it was damaging the compression tip, from whose lever the device was worked, and also wearing the exhaust valve lifting rod, so I had reluctantly to take it off. I found it a great boon, when stopping for restive horses, to do away with the "piffing" noise, or to stop the same noise if horses were about, when running down hill cooling the engine, or when starting, etc.

Yours truly,

Bolton, 11th August, 1900.

"NOVICE."

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—With reference to Mr. T. Smith's letter in your last issue regarding the exhaust valve lifter as fitted to his Beeston quad, I have ridden a Beeston trike some months, and found exactly the same trouble as described by Mr. Smith. I have got over my troubles by having a Wilkins and Boon Bowden exhaust valve lifter fitted, which I find works excellently, and I am sure if any motor-trike rider once gives this device a trial he would never ride a trike or quad without one. It consists of a lever and spring to open valve, and is actuated by a Bowden wire and lever fitted to the handle bar. It was devised and is made by Mr. A. Boon, of Messrs. Wilkins, Boon, and Co., at their Barnes depot. As far as I can remember, I believe they charge 21s. for fitting this to any make of trike or quad at their works, or can send sets of parts, if not convenient to take the machine to them.

Yours truly,

STUART W. PHILLPOTT.

Glencairn, Holmethorpe, Redhill,
August 13th, 1900.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In reply to the inquiry of your correspondent, T. Smith, jun., I can recommend him to have his exhaust valve opener altered so that it will be actuated by a separate lever working a Bowden brake wire. The only people I know of who fit this arrangement are Messrs. Wilkins and Boon, of Barnes, S.W., who could doubtless send the requisite parts to Stockport with instructions for fitting. The advantage of separating the exhaust valve lift from the brake lever will be not only to overcome the difficulty your correspondent has experienced, but also to enable him to leave the exhaust valve closed when it becomes necessary to apply the brake fully; the machine will stop more quickly with the compression at work than with it released by the opening of the exhaust valve.

The question of whether a trailer attached to a tricycle is subject to the provisions of the Light Locomotives Order of the Local Government Board relating to a separate vehicle drawing another is a rather important one of some nicety, which has never been authoritatively determined. It may be contended that the tricycle and trailer combined form one machine, in which case the painting of the name and the restriction of pace will not apply. But if your correspondent wishes to be in a position to claim that his tricycle and trailer constitute one machine he should take the precaution of paying the two guineas tax for a licence for a carriage having four or more wheels, the production of which licence would be evidence of bona fide belief that the combination constituted one machine.

Yours truly,

A. J. WILSON.

168, Clerkenwell Road, London, E.C.,
August 11th, 1900.

EPICYCLIC GEAR FOR VOITURETTES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Could any of your readers tell me why some English voiturettes are not constructed with epicyclic gears, thus dispensing with belts and clutches? Let us take the common type of voiturette—3 h.p. water-cooled motor geared through a pair of spur wheels to the rear axle by chains (or it may have a live axle). Now, could not a vehicle of this type be constructed with three epicyclic gears mounted on the countershaft to give two speeds and a reverse? The motor would transmit its power to these gears by bevel gear so that one of the gears when held by its brake would give a reverse. It seems to me that this system of transmission possesses all the advantages of spur gear, (i.) with the wheels not in mesh; (ii.) with the wheels in mesh, because there is no danger of teeth-stripping, as in (i.), and no need of clutches (or any similar mechanism), as in (ii.).

Yours truly,

R. A. COBB.

29, Dalby Square, Margate,

COMMERCIAL TRAVELLERS AND MOTOR-CARS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Referring to our par last week concerning a Cardiff commercial traveller adopting a motor-tricycle, it may be of interest to mention that we lately supplied a Swansea commercial traveller with a Star car of the phaeton type, which has been fitted with a hood and other special attachments to meet the peculiar requirements of Welsh roads. This car was severely tested during the rough weather experienced both before and after the last Bank Holiday. It is sufficiently commodious to take in a few extra parcels or a couple of customers if needs be, which could not be entertained on a tricycle.

Pontypridd,

August 13th, 1900.

Yours truly,

MORRIS BROS.

MOTOR-CARS AND THE FOURTH VOLUNTEER INFANTRY BRIGADE CAMP.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—When I was making arrangements for the four weeks emergency camp of my brigade I proposed the employment of a motor-car for communication with post and station. Some of my staff had misgivings, but the venture was made. The result was a decided success, although our experiences also convey a warning.

For the period of the camp the car made several journeys a day, bringing and taking down three mails and carrying a large number of officers and their friends. On many occasions a single mail consisted of about three hundredweight of letters and parcels, there being sometimes upwards of 3,000 men in camp at one time. But for the car we could only have had one delivery and despatch a day. Besides this work the car was several times used in connection with manœuvres, and on some days ran from 35 to 40 miles. It is admitted by all the staff that it would have been impossible to get the same work done by any horse conveyance without two teams and two drivers, and instead of the journey being done in fifteen minutes the one way and thirty-five the other—the road having a heavy rise in one direction—the time would have been half an hour the one way and an hour the other. It is also a great advantage in a camp to have a vehicle which is ready to start at any moment.

There is another side to the picture. During the first fortnight we had a good car, and only on two occasions was there any delay, and then only for about ten minutes. The car was, however, once off from a part having to be replaced, which could not be done on the spot. This car was under engagement elsewhere, and we had to be content with another, which was not nearly so satisfactory. To do the company justice from whom we got the cars, they did not profess to have a sound car available for the second fortnight, and only sent the one we used on being pressed, as we could not do without a conveyance of some kind. But, undoubtedly, although it did a great deal of work, the mishaps of the last fortnight were not a good advertisement for the new locomotion. I would strongly urge three things—(1) that companies should rather decline an order than bring discredit on a rising business by sending out an untrustworthy carriage; (2) that they should have the courage to supply themselves with a good stock of vehicles for hire, so as not to be sending out worn-out or shaky machines; and (3) that they should send no carriage to the country except in the hands of a man who can replace parts, and without sending with the car a box containing all spare parts necessary to replace those which have the most tendency to give way.

Yours truly,

J. H. A. MACDONALD.

Edinburgh, August 13th, 1900.

IRISH ROADS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I am afraid Mr. Mecredy's letter re Irish roads will do harm. The road authorities in Ireland are apathetic enough, goodness knows, and most of them have no conception of what a good road is, for they have never been on one. If these men get hold of Mr. Mecredy's letter they will "sit tight" and do

nothing, accepting his remark that "perfect touring, either for motor-car or cycle, can be enjoyed in this country" as a certificate that the roads in Ireland cannot be "bet." When Mr. Meccredy took his tour the roads in Ireland were at their best, and they will continue so for about another month. Then the process of spreading loose stones will commence, and continue for two or three months. And these stones will be left for the traffic to roll in, or drive to the side of the road—an operation which takes some months—consequently, not till May are the roads fairly fit to go on, but never are they absolutely free from loose stones. For six months at least out of the twelve it is perfect torture to ride a bicycle on most of the roads, and, I should say that pneumatic tires of motor-cars would have but a short life on them.

Yours truly,
Bann-aboo, near Wexford, J. R. MAGRATH, Colonel.
13th August, 1900.

THE RENAULT VOITURETTE.

To THE EDITOR OF *The Motor-Car Journal*.

SIR,—We are surprised to read in the July 14th issue of your journal a note to the effect that Mr. C. Friswell had secured the sole agency for the sale of our automobile voituresses in England. We think it right to inform you that we have given no invitation whatever to Mr. Friswell, and that we have never granted to him the agency of our firm. We should add that we have given no licence for construction in England. All our voituresses are made in France, and should bear the mark "Renault Frères, Constructeurs, Billancourt, Seine," on the differential case, upon the rear axle, and on the speed-changing gear case, as well as a metal plate on the body of the car.

We should be glad if you will kindly publish this letter in order to avoid confusion.

Yours truly,
RENAULT FRERES.

Billancourt, France, August 9th, 1900.

CHARGING ACCUMULATORS.

To THE EDITOR OF *The Motor-Car Journal*.

SIR,—Re the letter in your last issue, it is with pleasure I herewith endeavour to give Mr. Francis Tidcombe the benefit of a little experience gained by myself regarding the charging of small portable accumulators. I have found that bichromate elements do not charge storage batteries efficiently unless they give a voltage largely in excess of the output of the cells when charged. For example, two accumulators, i.e., 4 volts, would require a "charging voltage" of 8 to 12, varying with the type of accumulator. Under these conditions only are you certain of getting the cells reasonably charged. Even if the three "primaries" purchased were of one quart capacity each, and were connected up to the accumulators (the last-named preferably in parallel, i.e., + to + and — to —), it is a question whether good charging would be obtained.

No! the best thing to be done under the circumstances, although the initial expense comes rather heavy, is, in my opinion, to purchase a small shunt-wound dynamo, giving a current of 5 ampères at 10 volts (price about £3). To drive this I would suggest a water motor; that known as "Chicago's Top" is to be specially recommended, being small, light, powerful (with correct water pressure), and comparatively cheap (about £2).

I think Mr. Tidcombe would be "at rest for evermore" as regards charging troubles if he invests in the above outfit, which can be obtained from Messrs. John J. Griffin and Sons, Sardinia Street, Lincoln's Inn Fields, W.C.

In regard to the period at which re-charging becomes necessary, this point is usually indicated by a rapid fall of the potential or voltage. Until this occurs the cells may be relied upon for the purposes of ignition. From the information given in Mr. Tidcombe's letter I should say the accumulators can be kept in use until the voltage drops to about 2.5 or 3; they should then be re-charged. Under no circumstances should the cells be

completely discharged, otherwise the deterioration of the plates will ensue.

Yours truly,
W. G. BELL.

7, Loudoun Road, St. John's Wood, N.W.
August 13th, 1900.

THE BONNEVILLE VARIABLE-SPEED GEAR.

A NEW variable-speed gear suitable for motor cycles and voituresses has lately been introduced by M. L. Bonneville, of Toulouse, France, and of which illustrations are given herewith in Figs. 1 and 2. It consists of a train of reducing gears enclosed in a steel case *E*, concentric to the axis of the motor, and gives two speeds, and what is termed a "free wheel," that is to say, the motor can be so disconnected from the driving gear that it can be kept in operation even when the machine is at a standstill. When this is the case all the gear in the box *E* is at rest, and to start the cycle or car it is only

FIGS. 1 AND 2.

necessary to tighten the hand brake *F* round the drum *E*. The motor then transmits its power through the speed reducing wheel train in the ratio of 6 to 1, giving the slow speed; the fast speed is obtained by making a rigid connection between the motor shaft *A* and the gear box *E* by means of the clutch *L*. At the high speed none of the reducing gear wheels are working, so that no additional noise or wear is caused.

The gear is controlled by the intermediary of the small levers *O P* carried on a shaft *R* supported above the tricycle axle. Presuming the motor is at rest it can be started by means of the free-wheel sprocket *F*, actuated by pedal or hand-driven chain-

gearing. The lever is then pushed over from the centre of a quadrant, this giving the slow speed, the high speed being obtained by pulling the lever over in the opposite direction. In the case of a tricycle the gear is attached to, and entirely supported by, the motor, so that any jolting or vibration due to uneven roads is transmitted equally to the motor and gear, thus relieving the gear wheels of strain. When adopted in a voiturette the gear can be fitted to one of the intermediary shafts.

MOTOR-CARS ON THE CONTINENT.

(From Our Own Correspondent.)

The Spa and Ostend Automobile Meets.

WITH the possible exceptions of the hill-climbing competitions to be held in the autumn no further automobile races are likely to be decided in France this year, and consequently the greatest interest is being evinced in the Spa and Ostend meets, which will take place at the end of the current month. At both places the most capable drivers and the fastest cars in France should be seen, for men and vehicles alike are simply spoiling for a race. Why, it was only with Paris-Toulouse that the majority of *chauffeurs* commenced to race with their new cars, and now, having had their appetites whetted, they must forego the pleasure of again racing upon French soil, for the remainder of this year at any rate. Spa and Ostend, however, afford them a couple of opportunities of indulging in the sport, and that they will avail themselves of these opportunities cannot be doubted. The Spa meet is already well known, for this is the third year that it has been held, and as it precedes the Ostend fixture I will give its programme first. The categories into which the competing vehicles will be divided are as follows:—1. Voiturettes weighing less than 400 kilos and fitted with motor of less than 4 h.p. 2. Voiturettes weighing less than 400 kilos and fitted with motor of 4 or more h.p. 3. Cars weighing more than 400 kilos and fitted with motor of less than 8 h.p. 4. Cars weighing more than 400 kilos and fitted with motor of from 8 to 12 h.p. 5. Cars weighing more than 400 kilos and fitted with motor of from 12 to 15 h.p. 6. Cars weighing more than 400 kilos and fitted with motor of from 15 h.p. upwards. 7. Motor tricycles. Proceedings will commence on Sunday, the 26th instant, when the cars exceeding 400 kilos in weight will race over the same 185 kilometres as utilised last year. This route is from Spa by way of Bastogne, Marche, and Aywaille, back to Spa. Upon the following day the small fry will race from Spa via Vielsahn, Fraiture, Borna, and Aywaille, back to the starting-point, a total distance of 105 kilometres. Tuesday, the 28th instant, will see the tricyclists competing over the Bastogne-Marche route of 185 kilometres, and the two following days will be devoted to a congress and festivities. The prizes offered are considerable, and range in value from £28 for the first in the big car class to 33s. for the fourth among the cycles. A big party is expected to travel through to Spa from Brussels on the previous Saturday, the journey being broken at Huy and Aywaille. This party is being organised by the Automobile Club of Belgium, and it is also to the Club that entries for the races should be made. The fees for the courses are 50 francs for the cars, 30 francs for the voiturettes, and 20 francs for the cycles. It is very certain that the majority of motor men will not remain in Spa until the finish of the meet, for it is on Thursday, the 30th instant, that, for the first time in the annals of automobilism, a series of races will take place upon a track. It is to Ostend that the honour of first organising such races belongs, and the Wellington Hippodrome will be utilised for the holding of the events. Special precautions are being taken to render the surface thoroughly firm, so that the big cars can be let go for all they are worth. The programme is as follows: 1, Voiturette and motor-cycle gymkhana; prizes, six *objets d'art*. 2, Motor-cycle race, distance 50 kilometres; prizes, £40, £16, £10, and £6; entrance fee, 10 francs. 3, Voiturette race, distance 50 kilometres; prizes, £60, £24, £12, and £8; entrance fee, 25 francs.

4, Car race, distance 100 kilometres; prizes, £120, £80, £40, and £24; entrance fee, 50 francs. Entries should be made to the Wellington Hippodrome at Ostend, or to the office of the "Vélo" at Paris. The track measures 2,700 metres, or upwards of $1\frac{1}{2}$ mile. Among the entries already received are the names of Levegh and Jenatzy, and doubtless many other leading racing men of the day will also participate. In the event of the practicability of racing under these circumstances being clearly demonstrated, there can be but little doubt that other moto-dromes will be exploited, for a means of satisfying the racing fever must be found. No wonder, then, that the experiment at Ostend is being watched with the greatest interest, and that a large number of Frenchmen interested in automobile matters have already signified their intention of being present. From a social point of view the meet will also be of interest, for it is more than probable that the Shah of Persia will be a spectator of the races. He will be in Belgium at the end of the month, and is reported to have expressed the intention of going to Ostend and witnessing the automobile sports. Should this prove to be the case it will certainly do much to ensure the success of the meet, and if by chance he put in an appearance on his new Serpollet, what a reception he would have, to be sure!

The "Simplest" Voiturette.

"LA Plus Simple," or the "Simplest," is the name given to a little two-seated voiturette lately turned out from the works of M. René Legros, of Fécamp (Seine-Inférieure). It is driven by a 4 h.p. single-cylinder air-cooled motor, fitted in the fore part of the frame as shown in the accompanying illustration. The car is gear driven, the pinions working in an

oil bath. The ignition is electrical, a feature being the employment of a small pedal to cut off the electrical current when necessary. Steering is controlled by an inclined hand-wheel; a pedal actuates a band brake on the differential gear, while there are band brakes operated by a hand lever on drums attached to the hubs of each of the rear wheels. The car, which weighs about $4\frac{1}{2}$ cwt., can, it is claimed, attain a speed of 35 kilometres per hour and mount gradients of 12 per cent.

The Flotte-Lemaître Case Again.

THE Flotte-Lemaître case has advanced another step, and the Versailles Court has, acting upon the report of the medical men deputed to examine Flotte, assessed at £800 the amount of damages payable by M. Lemaître to the injured mechanic. I say "advanced another step," for if reports be true the affair is not yet finished, M. Lemaître having the intention to again appeal, this time against the amount awarded by the Court to the plaintiff. And this amount is in reality but a third of that claimed, for Flotte considered himself entitled to £2,400. M. Lemaître must be pretty firmly convinced of the justice of his cause, for he is contesting every inch of the ground with the same determination

that he has so often shown in automobile races. When will it end?

Belgian Roads.

ONE of the greatest tribulations of the automobilist touring in Belgium is the terrible condition of many of the roads; indeed, some of them are quite impossible for self-propelled traffic. But what can be expected when the State, instead of setting an example by keeping the roads under its direct control in irreproachable order, neglects many of them to such an extent that the motor man who has the slightest regard for his car and for his personal comfort is compelled to studiously avoid them. The route from Brussels to Antwerp may be cited as an example, and again that leading from Brussels to Malines, via Vilvorde and Sempst. Why, but quite recently the members of the newly-formed Moto Club of Belgium, who were engaged upon their opening run, were compelled to make the journey between Brussels and Malines by way of Perck and Elerdyt, finding the local routes infinitely preferable to the main road. There is considerable talk in automobile circles of organising a campaign on this question, but unless energetically pressed home nothing is likely to result, for the Government has a careful eye to its finances, and road-making is no inexpensive item.

FURIOUS DRIVING CASES.

AT the West London police-court last week, Mr. Harry Lee, residing at 149, Lupus Street, Pimlico, was summoned, before Mr. Lane, Q.C., by the police for unlawfully driving a motor-car at a speed greater than was reasonable and proper having regard to the traffic. Mr. Arthur Newton defended. Police-constable 517 T said the defendant drove at the rate of seventeen miles an hour along the Chiswick High Road. He judged the rate of speed as he himself rode a bicycle and had some difficulty in keeping up to the car. Mr. Newton pointed out that motor-cars, owing to the noise they made, gave the impression that they travelled much faster than they really did. The defendant said that he was not travelling faster than seven miles an hour. The car was purchased in Paris for £1,000, and could be brought to a standstill immediately. Mr. Newton asked his worship for an expression of opinion as to what constituted a dangerous rate of speed. Mr. Lane, Q.C., did not think the police would interfere if a car was driven at a fast rate in a road where there was little or no traffic. Under certain conditions twenty miles an hour might be, he said, a perfectly safe and proper speed, but in the case of a car managed with less skill and without the same delicate adjustment twelve miles an hour would be a dangerous and an improper speed. In the interests of the public he fined the defendant 5s., with 2s. cost.

AT the Worthing Petty Sessions last week Albert Edward Knight, a motor-car instructor, pleaded not guilty to a summons charging him with driving a motor-car furiously in the Broadwater Road on April 23rd. Police-constable Pennicott deposed that on the evening in question he was on duty in plain clothes when he saw the defendant and another man come over the railway bridge in a motor-car. The car was going at about eighteen miles an hour, and several children, who were playing in the road, had to run out of the way. The car was certainly driven to the common danger of the public. Defendant said it was impossible for the motor to go eighteen miles an hour. Superintendent Bridger deposed that on the evening in question he was driving through Broadwater Village when he met the defendant, who was driving a motor-car in the direction of Worthing. The car was going at a most dangerous pace, and witness had great difficulty in holding his horse, which shied at the car. Defendant stated he had driven motor-cars for five years, and had never had a complaint made against him before. He should say they were not going at more than seven or eight miles an hour. George Wills, of Chapel Road, Worthing, deposed that on the evening of the 22nd April the defendant brought the motor-car to his yard to be examined, and he found that the engine was defective. It had lost compression entirely, and it was impossible for the machine to have gone at more than nine miles an hour when he saw it. By the Clerk: He could not remember at what time of the day it was the defendant came to him. The Bench held that the case was proved, and imposed a fine of £2 and £2 3s. 3d. costs, the chairman observing that it was quite time the reckless driving of motor-cars was put a stop to.

AT the Steyning Petty Sessions last week George Thomas Langridge, of Epsom, was summoned for driving a motor-car at a greater speed than twelve miles an hour on the highway at Storrington on July 29th. The offence was denied. Police-constable T. Bristow said about 4.45 on the afternoon of the day named he timed the motor-car which the defendant was driving for a quarter of a mile, which it covered in fifty seconds. As defendant got near him he shouted, "One minute, sir, please," and defendant slowed down a little, but did not stop. Witness tried to take hold of the handle, but defendant pushed him aside.

Witness then caught hold of the back of the motor and defendant's coat. Witness hung on till the defendant stopped. He took defendant's name and address. Harry Eade, Ashington, judged the pace to be not less than seventeen miles an hour when he first saw defendant. Defendant was sworn, and said he had been a cyclist since 1874, and during the last eighteen months had driven a motor 150,000 miles, and had never been stopped. He had never passed a horse at a rate of more than six miles an hour. He denied that he was going at the rate alleged, and said if he had known the policeman was there he should have done just the same. He was not going more than twelve miles an hour. Ordered to pay 19s. 6d. costs, no conviction being recorded.

LA SOCIÉTÉ DES ANCIENS ÉTABLISSEMENTS PANHARD ET LEVASSOR v. THE PANHARD AND LEVASSOR MOTOR CAR CO.

IN the Chancery Division, a few days ago, Mr. Vernon Smith, Q.C., mentioned a motion in this action to Mr. Justice Cozens-Hardy. The plaintiffs seek an injunction to restrain the defendants from trading under the names Panhard and Levassor. Counsel stated that the defendants had put in affidavits which raised a number of defences, and the affidavits would have to be submitted to the French directors of the plaintiff company. He did not think the motion would be effective during the present sittings, and asked that the matter might be ordered to stand over until after the Long Vacation. Mr. Justice Cozens-Hardy acquiesced.

AN UNPROVOKED ASSAULT.

THE motor-car does not find favour in the sight of two stablemen down Putney way. On Bank Holiday Mr. Robert Tweedy Smith, solicitor, of Carey Street, W.C., put his car up at Mr. Beach's stables there, as it was raining. Henry Sexton and Alfred Sexton, stablemen in the employ of Mr. Beach, seemed to resent the presence of the car, and displayed a bias against motor-cars in general. Some hours later, when Mr. Smith and his friend were about to drive off, the stablemen, who were under the influence of drink, suddenly attacked him. They pinned him to the wall, and hit him savagely about the head and body. Mr. Rawlings corroborated the complainant's evidence, adding that he never had witnessed such a savage assault, and that the men acted as though they were disappointed at not receiving a "tip." These facts came out at the South Western Court on Saturday last, when the two men were summoned for the assault. Mr. Rose, in addressing the defendants, said: A Bank Holiday, some beer, and an objection to motor-cars—these were the moving elements in this absolutely unprovoked assault. You must each of you pay 20s. and 2s. costs, or go to prison for fourteen days. The money was paid.

MOTOR-CAR ACCIDENT NEAR ALCESTER.

A MOTOR-CAR accident happened on Tuesday, last week, on the road between Alcester and Stratford-on-Avon. Messrs. Eadie, Smith, and Edmunds, all of Redditch, were returning on the way from Stratford, on a De Dion voiturette, and on descending Red Hill the car overturned, and the occupants were thrown out with considerable force. Mr. Smith's left arm was broken, and his face badly injured. A slight injury was sustained by Mr. Edmunds to his left arm, but Mr. Eadie escaped unhurt. From particulars we have received, it appears the steering wheel (left side) dropped off through the axle breaking.

THE Bedford Motor-Car Syndicate, Limited, is being voluntarily wound-up.

APPLICATION has been made to the U.S. Post Office Department for an automobile mail carrier for Washington County, Pa., to carry mail on the old National pike between Washington and Brownsville.

THE Worshipful Company of Coach Makers and Coach Harness Makers of London offer a scholarship of £25, tenable for one year at the Higher Technical Day Class for Road Carriage Building at the Polytechnic, Regent Street, London, W.

RECENT additions to the list of members of the Automobile Club include the following gentlemen: H. M. Beddington, A. R. Bower, Clement Braby, Rev. H. C. Coote, W. G. Crombie, W. K. D'Arcy, Maurice Egerton, H. P. Fernald, L. F. Giers, G. H. Healey, John D. Hill, W. R. Holmes, Sidney T. Hone, W. M. Leon, O. E. Lord, Wm. Hy. Schneider, F. S. St. Quintin, John St. L. Strachey, Hon. H. N. Sturt, Edgar Thornton, Charles Threlfall, Arthur Thwaites, T. U. Thynne, Edgar Webster, Arthur Gerald Weguelin, and G. St. Maur Willoughby.

THE Motor-Car Journal.

Vol. II.]

LONDON, SATURDAY, AUGUST 25, 1900.

[No. 77.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

AN excellent illustration of H.R.H. the Prince of Wales and the Hon. J. Scott-Montagu, M.P., on the latter's 12 h.p. Daimler, appears in the last issue of the *Sphere*. The picture is reproduced from a photo taken at Highcliff Castle, Hants, on the 14th July. Unfortunately the writer of the notice accompanying the illustration is not very happy in his statements with reference to the Prince of Wales's connection with motor-cars, for in one place it is stated that this was "the first occasion when the Heir Apparent boarded a motor," and in another, "so far the Prince has

not gone in for a motor-car of his own, but he may yet possess himself of a machine." It will apparently be news to the writer of the article in question, although not to readers of the *Motor-Car Journal*, to learn that it must be nearly three years since the Prince of Wales made his first trip on a motor-car, and that not only has H.R.H. had a motor-phaeton of his own for over two months, but that he has, as stated in our last issue, two more vehicles on order. Royalty is certainly becoming a very appreciative patron of automobilism, and on his way to receive the Prince of Wales at Wilhelmshohe, on Thursday, the German Emperor made use of a motor-car which had been sent there by the German War Office.

Motor-Racing in Ireland.

THE first motor race on an Irish track took place last week at Navan sports, and was very well received by the public. Four competitors competed, all being mounted on Ariel motor-tricycles. The preliminary heats were over a distance of two miles, and in the first J. Macdonald won easily from H. Kenny; whilst in the second J. C. Cooney came in well ahead of R. W. Stevens. In the final, Cooney also proved the winner, doing the distance in 11min. 0½sec., which is very good for a gravel track. Great interest was centred in the event, and already some other fixtures of a like nature have been billed.

Motor-Cars at Bournemouth.

THE dead-set which is being made in certain quarters against the motor-cars at Bournemouth has already been referred to in these columns. The Bournemouth *Observer*, in commenting on the matter, considers that this "motor-phobia" "principally attacks those who have never entrusted their susceptible personages to the exhilarating motion of the motor-cars, and whose requirements in the matter of rapid transit have not enabled them to appreciate the great advantages of this means of conveyance over the leisurely cab and creeping omnibus. More especially does the disease take possession of the official mind, and it seems likely to create a perversion of public authority as typified in the constabulary executive."

Blocking their Way.

OUR contemporary points out that several ways have been officially tried to check the adoption of the motor-car system in the town. It was sought to impose harassing conditions by making the cars run where they were not wanted, and could not possibly make a remunerative route. Such an attempt was found to be *ultra vires*. The Horse Committee of the Town Council then agreed to recommend the Council to withhold the licences of the drivers. At the last moment they were bound to admit that this proposed action was legally unwarrantable, and they had to withdraw their recommendation. Now the symptoms indicate that the question of speed is to be the one crucial point to which they are to direct their attention, with the view of blocking the progress of the cars.

Judging the Speed.

THE question is very wisely asked, how many people are capable of gauging the speed of a motor-car? How many constables can be regarded as trustworthy on such a point? No doubt there will be cases of reckless driving of motor-cars, just as there are with horse-drawn vehicles, which should be dealt with by a firm judicial hand. Up to the present, such cases have been relatively few throughout the country, and in Bournemouth it has been pleasant to note the carefulness and dexterity of the drivers. The *Observer* adds that it is satisfactory to note that magistrates of experience in giving their decisions in such cases are very slow in accepting the uncorroborated testimony of the police.

Advice to Provincial Magistrates.

AUTOMOBILISM is a comparatively new thing. With its advent has come the possibility of a new public offence, and an additional opportunity of police vigilance. Hence, metropolitan and stipendiary magistrates, who are experts in reading the promptings of official testimony, are very chary in convicting on a charge of over-driving a motor-car. It will probably be some time before a like-mindedness is displayed on the provincial bench. It will require a more prolonged familiarity with automobilism, and possibly a few appeal cases with judgments reversed on appeal, possibly even a special statute, to protect motor-cars from the influences of prejudice and feverish alarm, before they can be freely run without risk of undue interference.

Excessive Speed in Norfolk.

AT the Norwich Shire Hall last week Colonel Dawson drew attention to the speed at which motor-cars were driven along the road. He stated that an evening or so previously he was standing in his garden at Old Catton, and saw a car pass at the rate of twenty miles an hour, which he considered was absolutely improper. He asked if any steps could be taken to prevent such a speed. Mr. R. B. Longe suggested that the member of the County Council for the division should be requested to ask the Council what regulations were made,

and to make suggestions as to speed. The Chairman said he was the member for the division, and would carry out the suggestion. He thought, however, that if the gentleman who had been referred to was cautioned by the police it would be sufficient, as he might be unaware of the speed allowed by the County Council.

Porlock Hill Mounted by a Motor-Car.

It was only in our last issue that we chronicled the fact that the 16-h.p. Napier car was in the north of England. Now we learn that last week end it was creating new records in the west of England, achieving the distinction of being the first motor-car to ascend the well-known steep Porlock Hill, near Minehead. Of this hill, the "Contour" Road-book states that it is "a sheer descent with two twists near the bottom; there is scarcely any surface to this part of the road—it is more like a river bed." The three miles climb is equal to a lift of over 1,300 ft., and comprises gradients as steep as one in six. The attempt to mount the hill was, we understand, the result of a wager between Mr. S. F. Edge and a local hunting sportsman. A large party gathered to witness the failure of the attempt, but the 16-h.p. Napier upset all their calculations. With three persons up it took the worst slopes at a steady seven miles per hour, and covered the distance from the village to the road junction on the hill top in 17m. 35sec.

Business in a Motor-Car.

WHAT a convenience it would be were business men able to take their holiday in a motor-car. A member of our staff who has lately been vacating has been endeavouring to keep up his connection with the office work, but finds it rather irksome having to do things in strange surroundings and away from all the usual references. This, too, is a difficulty experienced by all busy people who are unable to entirely tear themselves away from business and professional worries. Mr. Fiske, an American millionaire, has, it is said, got over the worry by the utilisation of a motor-car. He lives in a suburb an hour's ride from New York and spends the two hours a day, which would otherwise most probably be wasted, in a motor-car, which has been fitted up as an office, and in which he works to and from his business place. There is a type-writing outfit in addition to the usual office fittings, so that he is able to fully appreciate the proverb, "Money is time." Whether such movable offices will ever be available for business men in this country when on their holiday is a matter of problematical conjecture.

Motor-Car Accidents.

FREQUENTLY have we referred to the habit of newspaper scribes giving the motor-car the discredit of every accident to horses or horse-drawn vehicles. An instance occurs in connection with the terrible accident to Miss Page, which has occurred in Hyde Park this week. After describing the way in which she was thrown and dreadfully injured, the reporter goes on to say: "It is thought that the animal shied at a motor-car." This seems a kind of concluding line to every report of the kind, and we would again protest against what is evidently a prevailing custom. To say "it is thought" a motor-car caused the accident is a very unfair way of putting the case, especially when the evidence as to a motor-car being near is absolutely *nil*.

Near Bonnie Dundee.

AFTER a trial for a number of weeks the two motor-cars which were substituted for the ordinary horse 'bus on the run between the village of Downfield and the Dundee steam car terminus at Fairmuir have been stopped. Several reasons have been advanced by village gossips for the stoppage of the vehicles, but what appears to be the most accepted by the travelling public of the district is that both of the vehicles put on the route were altogether unequal to the traffic. One fact certainly must

have led to a change, and that was the unpunctuality of the running. No route can be expected to meet with the wished-for traffic if the public have to wait about for a length of time in which they can almost walk the distance. Then on rainy days nothing could have been more miserable than being seated in the open car.

A Quick-going Family.

MR. W. K. VANDERBILT, JR., whose fast Daimler machine has so disturbed Newport, inherits the love of speed that has been in the Vanderbilt blood from the first. With the old Commodore, with his brother, Captain Jacob, and the former's son, William H., it was fast horses. William H.'s day of triumph was when, with Maud S. and Aldine, he lowered the record for a double team in harness. With Cornelius and William K. it was fast railroad trains, and the Empire State Express is the monument to the love of speed in that generation of the family. Now come Cornelius, Jr., and William K., Jr., the latter with his Daimler, and both with yachts. The performances of the 70-footers, Yankee, Rainbow and Virginia, sister boats to the Mineola, are of present day fame. There must be something fascinating about motoring for it to appeal so strongly to such a quick-going and sporting family.

Wiltshire on the Watch.

THE Standing Joint Committee of the Wiltshire County Council has been considering the question of the speed of motor-cars. Two or three different views as to the responsibility for watching the drivers were presented, and ultimately those who wanted to thwart automobilists seem to have got very little satisfaction. The clerk suggested that it was the duty of the police to check an excessive rate of progress. The chief constable, however, contended that the duty also rested with the public, who by complaining to the police could effectively set the law in motion. The drivers of motor-cars, it was said, possess something of the elusive tactics of a Boer general. They are unknown in the district through which they whirl, and by the time the nearest constable had been apprized of an unseemly rush the driver would be miles away, unless something happened to his apparatus. When complaints become sufficiently general in the county of Wiltshire the chief constable has offered to put a policeman on the look-out on certain roads.

Motorists and Hotels.

BICYCLISTS have been a boon to many innkeepers on the main roads, but motorists promise to be an even more profitable class of patrons. They feel the want of liquid refreshment both to wash the dust down their throat and, as is often the case, to revive the circulation after being chilled by the rapid motion through the air. Moreover, they belong, as a rule, to a class having greater spending powers than the average cyclist, and go in more for the luxuries of life in the shape of wines and cigars. It would pay innkeepers up and down the country to keep supplies of petrol, as the fact of their doing so would attract motorists to them and so be a new source of profit.

Over the Alps.

MRS. PENNELL's pen and Mr. Joseph Pennell's pencil make a combination that secures for the little volume published by Mr. T. Fisher Unwin a favourable reception. This is entitled "Over the Alps on a Bicycle," and with the three previous books of the series completes the record of a journey from London to Rome in the years 1884 to 1897. Mrs. Pennell records many chatty reminiscences, and although the ascents she made would not always be acceptable to the motorist, many knights of the steering wheel will appreciate the description of the route from Dijon to Lucerne. At the end of the book is given a summary of the route, with some notes on the character of the roads which were traversed.

Accidents in France.

ACCORDING to the "Velo's" statistical table, the four great means of transport were last month responsible for 1,073 accidents in France, giving rise to 114 deaths and the injury of 959 persons. No deaths are attributable to the automobile, and the sum total of its offences is the injury of 34 persons, some of the victims being automobilists themselves, others members of the general public. The bicycle's black list shows a total of 98 accidents, which brought death to seven and injuries to 91 of the victims. The railway figures to the extent of 29 fatalities, and is also responsible for the injuries sustained by 36 people. Only one other class is included in the "Velo's" list—the "fiery steed"—but, as is invariably the case, more accidents have occurred during the month by the use of the horse than by the employment of all these mechanical means of transport. To his charge must be laid 876 mishaps, resulting in injuries to 798 and death to 78 victims. It is truly an appalling list! Were the horse compelled to pass an expert with regard both to his construction and his behaviour, as is the motor in France, we should probably hear less of his dangerous eccentricities.

A Warning to Manufacturers.

THERE is a practical tone about an article in the *Coach Builders' Journal*, in which attention is drawn to the danger of the motor-car drifting into its wrong sphere, "for the reason that motor-vehicle makers have been devoting their entire efforts to making it a thing of pleasure and an expensive luxury for the aristocrat." After pointing out other matters, our contemporary adds: "It is the commercial world which is waiting for a motor to take the place of the horse. The motor is essentially a thing of work, its mission is to abolish distance by means of more rapid transit than is possible under the circumstances which now obtain; to carry loads, whether of passengers or goods, at, if possible, a cheaper rate, though this is not so much an object so far as passengers are concerned as the saving of time, and fortunes can be made out of the passenger traffic of London and the large cities of this kingdom alone. One or two motors might be made and lent to either or both of the great bus companies in London, who would gladly put them to practical tests. If they were found more economical than the horses now in use, the certainty of increased dividends for their shareholders would ensure their speedy adoption. We presume that the primary object of the motor engineers when going into business, like that of every one else, is to make money. We think, however, that until they bring themselves to look upon the motor as a substitute only for the horse, capable of doing more work more economically and more expeditiously, as is the case with the railway locomotive, and to understand that the general public and not the aristocracy, or any other single class, will be their best customers, motors will be used only to a very limited extent."

On Swiss Mountains.

MR. CHARLES P. SISLEY has done well in taking a motor-car into Switzerland and giving additional proof of its value amid the mountainous passes of that favourite country of the tourist. That it was a French car—a voiturette with a 6 h.p. engine—need not arouse any jealous feeling in the minds of patriotic Britishers, for an English vehicle can be obtained which would have been equally reliable and given quite as satisfactory results. The adventure was as much a trial for the motorist and his companion as for the car, for while ascending gradients they had to be ready to jump off at a moment's notice. Any slight error of judgment might have hurled them down a precipice. Perhaps the most exciting moments on these mountain roads occurred when passing vehicles. In Switzerland the horses are not yet as accustomed to the motor-car as they are in France, and it was often hard to say whether the motorists or the occupants of the other vehicles were most in danger of instant precipitation into space. Once, when passing through a village near Interlaken, a horse attached to a farm cart was standing outside an inn. The motor-car coming swiftly along did not seem to disturb the animal until

arriving almost abreast of it. Then without warning it broke loose, overturned a water trough, scattered all the poultry in the yard, and made a wild dash after the car. For half a mile or so it was a desperate contest—the mad animal close behind the occupants of the motor-car, who were piling on all the speed in their power; then gradually the horse tired, but it did not actually cease running for several miles.

Tramways v. Motor-Cars.

THE merits of tramways and motor-cars have often been discussed during recent weeks, to the advantage in almost every instance of the motor-car. Certainly the greater mobility of the latter, and the fact that it requires no great preparation of road surface, and does not monopolise half the roadway, are factors to be considered and regarded in these days. Probably in the future we shall have long lines of electric trams supplemented by motor-omnibuses in the crowded areas as well as the less thickly populated ones, for tramways would never be appreciated in the central parts of great cities, and in many

A MERRY PARTY ON THE WAY TO GUILDFORD.

localities would never be profitable. In such circumstances the motor-vehicle will be undeniably useful and profitable.

A Business Visitation.

"THE head of a firm who wishes to see his agents throughout the country, would like to arrange with a gentleman having a motor-car to tour with him on mutual terms, one to three months.—Address, c.o. — Advertising Offices." Such is an advertisement which has appeared in a business paper, and we reproduce it as suggesting a development of the usefulness of the motor-car, which should be of interest to our readers. To anyone with large business connections in out-of-the-way towns, as well as in the great commercial centres, the motor-car offers a means of conveyance that is comfortable in use and economical in time; for it certainly will save much wasted time and the confusion usually associated with railway travelling in a hurry.

Views of a Buxton Motorist.

MR. AUGUSTUS BEATSON, of Buxton, and a friend went by motor car from Buxton to Sheffield the other day, greatly enjoying the run, *via* Castleton and Fox House. When they were going back the "trembler" went wrong near Fox House, and, owing to the screw-driver having been left behind, they had the greatest difficulty in adjusting it, and it caused considerable delay; in fact, they did not reach the bottom of Taddington Hill (they returned *via* Baslow, Hassop, and Ash-

ford) until about midnight. Here they had another delay from the same cause, and it looked at one time as though they would never get the engine going, but would have to spend a night with the glow-worms! However, they managed to get back to Buxton all right. There are three brakes on the car, so there is absolute control over it, and as an experiment Mr. Beatson has run into the coach-house at about twelve miles an hour, and pulled it up dead! The brakes on his new car are still more powerful. A motor-car, like a horse, requires a drink occasionally—and so of course does the driver!—and when Mr. Beatson was driving to Derby last week he stopped at an inn for this purpose, and got into conversation with a "bobby," and he admitted that it was impossible for him to tell whether a car was going at six or nine miles an hour. No one can tell to a mile or two what the speed is, unless on a measured road and with the aid of stop watches. The convictions for furious driving are perfectly ridiculous, and if drivers of motor-cars are fined, a great many drivers of horses in and around Buxton ought to be also, for they certainly drive at a "furious" pace sometimes, and cannot pull up sharp the same as a motor car can. Mr. Beatson says he cannot tell how many times he has been thanked for either slowing down or stopping dead—just as circumstances require—for restive horses, and the driver and also several of the passengers of the Derby and Matlock coach thanked him the other day for stopping dead for them to pass. The sooner the owners (especially the "great unpaid") and drivers of horses recognise the fact that motor-cars have come to stay, and educate their horses so that they are not frightened at them, the better will it be for themselves and everyone else. Such are the views of a Buxton motorist, and they will be endorsed by all our readers.

◆ ◆ ◆
**"Horseless Vehicles,
 Automobiles, and
 Motor-Cycles."**

◆ ◆ ◆
 This is the title of a work from the pen of Mr. Gardner D. Hiscox, an American engineer, which has just been published by Messrs. Sampson Low, Marston, and Co. As its title indicates, the book is quite a comprehensive review of the motor-vehicle and covers the subject in a readable manner with a great deal of attention to detail and numerous practical particulars of considerable interest. The contents commence with some introductory historical notes and the first type of automobile dealt with is the steam machine as being the forerunner of the industry. Steam vehicles, motor appliances, with a very lucid description of the Serpollet boiler, the pioneer of light steam generators, are described together with details such as burners and arrangement of tubes. Then a chapter is given to specialties in automobile construction, comprising the compensating bevel gear train, two pinion differential gear, tires for automobiles and roller bearing axles. Under steam propelled vehicles and automobile carriages, road rollers, traction engines, trucks, fire engines, motor-vehicles for heavy traffic, and various types of modern steam automobiles are handled. A chapter is devoted to horseless vehicles with explosive motors, one to electric ignition, while in another the carburettor, a very essential part of the petrol-motor, and the various types are explained, as well as operating devices and speed gears, friction clutches, steering gear and silencers, etc. Next to be treated are electrical vehicles, one chapter being devoted to "How to Build an Electrical Cab." Compressed air power for vehicles occupies another chapter, and the work concludes with miscellaneous vehicles, motors, and appliances. The book also contains a list of patents on motor vehicles of various kinds, from 1856 to the time of publication; also a list of addresses of automobile builders in the United States, as far as known to the author at the time of publication. It is perhaps quite natural, in view of the fact that the author is an American, that American vehicles should receive the largest share of notice in the book, but it is with regret that we notice that such builders as Panhard and Levassor, Peugeot, and Mors, are not even mentioned, and that the Daimler vehicle is represented only by its carburettor. The books of reference on automobiles in the English language are, however, not too numerous, so that, despite the drawbacks above alluded to, the work will be found useful by many interested in the new means of locomotion.

◆ ◆ ◆
**From London to
 Leeds by Motor-Car.**

The establishment of motor-coach services has frequently been advocated in these columns, and we are pleased to learn that an attempt in the direction named is now being made. The credit for the new departure is due to Mr. A. E. Wynn, of Knaresborough, this gentleman having just started a service between London and Leeds. At present only one service per week in each direction is being carried through, but no doubt, if the experiment proves successful, further cars will be put on the service. At present the car is timed to leave London on Thursday mornings at 9 a.m., reaching Leeds on Friday evening. The return trip is made on Mondays, Leeds being left at 9.30 a.m. and London reached on Tuesday evening. The route followed is *via* Hatfield, Stamford, Grantham, and Doncaster, the stopping place for the night being the George Hotel, Stamford. The fare for the journey between London and Leeds is £2 2s. each way, with intermediate rates to Stamford and Grantham. It is interesting to note the conditions on which the car tickets are issued. The proprietor reserves the right to stop the car at any time if there is sufficient reason for doing so, and no person having booked a seat or taken a ticket shall have any remedy against the proprietor for so exercising his right except a return of the fare paid. If from any unforeseen cause the whole of the journey is not made by the car a due proportion of the fare is to be returned. All tickets are sold and places booked on this understanding. The inaugural trip was made on Thursday last week, Leeds being reached on Friday a few hours behind schedule time. Our Leeds correspondent writes that on the second trip, which started on Monday at 10 a.m. from Leeds, there were only two passengers, but probably when the fact that such a service is now available becomes better known the number of passengers will quickly increase. In any case Mr. Wynn is to be congratulated on his enterprise.

◆ ◆ ◆
**An Incident at
 Folkestone.**

◆ ◆ ◆
 MR. GRAHAME WHITE, who has lately been coaching Lord Wolverton in the management of a motor-car, had an exciting experience at Folkestone last week. He was driving his 12 h.p. Daimler with a full complement of passengers, including Lord Wolverton, Lady Haliburton, a coachman, and four children, from Deal to Folkestone, by way of Dover. The steep descent into Dover was negotiated in safety, and when the equally notorious hill into Folkestone was reached, the first and steepest part of that was also descended without thought of danger. Then the pace quickened, and Mr. Grahame White found to his dismay that the brakes had fired and burnt away under the prolonged strain. With admirable nerve, however, he set himself to conquer the difficulties of the situation. In the first place he reversed the engine; then he steered the car from side to side of the road in the hope of reducing its speed, but in vain; it surmounted every obstacle against which it was driven. Finally, he drove the car on to the pavement, between a lamp-post and a wall, the clearance being so narrow that, as Lord Wolverton says, "you could hardly have put a sheet of notepaper between the wheels and the post," then he pulled the car straight across the road and steered it through a narrow gateway into the yard of Folkestone Junction station. The alternatives here presented were either to dash into the station buildings or to slue the car round within an extremely narrow space while travelling at thirty miles an hour, heading it back through the gate and checking the momentum by turning up the hill. Naturally he chose the latter course. According to a newspaper account, all four tires were ripped off simultaneously as the car was wrenched round in its tracks, but the wheels held together despite the tremendous strain. Back through the gate went the car, round to the right, and at last it was brought to a standstill on the up-grade. But for the clear-headedness with which Mr. Grahame White grasped the only possible way out of the difficulty, the car would have continued its headlong course into the town, with results too terrible to imagine.

THE ROCHET MOTOR-CAR.

SINCE the Rochet car was first put on the market a number of changes have been made in it, the most notable of which is the placing of the engine under a bonnet in the fore part of the frame instead of at the rear. Fig. 8 shows the frame of the latest type of vehicle, complete with motor and transmission gear. This is so arranged that any desired form of carriage body may be mounted on it, and secured thereto by bolts. Fig. 1 shows the "duc touneau" style of body, with seating accommodation for six persons, but any other may readily and quickly be substituted for it. The frame is constructed from cold-drawn steel tubing with brazed joints, and is very rigid. All of its members are in internal communication, and it is made to serve as an auxiliary cooler for the cylinder jacket water. Two semi-elliptic springs in the rear and a transverse elliptic spring in front support the frame on the axles.

The Rochet motor is an adaptation of the Daimler engine, but it embodies a considerable number of improvements in the details of its construction. It is shown in Figs. 3 and 4, and has two cylinders, developing 6 or 8 h.p., according to size. Some vehicles have two of these motors on one shaft, which gives them 12 or 16 h.p. The two cylinders are cast in one piece and bolted to the crank case. All the moving parts, save the levers acting on the exhaust valves, are inclosed. The crank case has the usual splash lubrication, and a glass set in its side enables the operator to observe the level of the oil. The governor is within the case *J*, and the starting crank is worked from the front end of the vehicle. The cover *B* incloses a commutator to distribute the current for the spark, first to one and then to the other cylinder, electrical ignition being now employed.

The valve box is cast in one piece with the head. The fresh mixture enters at *T* and passes to one or the other cylinder,

while the exhaust gases pass out at *Z Z*. On top of the valve box are four screwed plugs, *a a c c*, which permit immediate access to the valves without dismantling the cylinder head; a meritorious feature. The two plugs *c c* over the inlet valves are formed to receive the sparking plugs *K K*. Two cups *M M* on the cylinder head are provided for the introduction of a few drops of petrol, when starting, to dissolve any gummy oil that may have clogged the piston rings. The governor is set to permit a normal speed of 750 revolutions per minute. The cranks are set opposite to minimise vibration. The speed of the motor is controlled by causing one or both of the exhaust cam rollers to run off from thin cams on to adjacent circular cams, thereby putting one or both of the exhaust valves out of action. The air supply to the carburettor, which is of the constant-level type, is warmed by passing around the exhaust pipe, and the mixture is diluted by an adjustable opening on its way to the motor. A small-screwed plug at the base of the carburettor permits of draining the latter of stale petrol, and also of lowering the level in case the apparatus becomes "flooded" by non-operation of the float. The exhaust valves are operated from a secondary or cam shaft, parallel with the crank shaft, and geared to it by spur gears in the ratio of 1:2. The piece transmitting the push from the cam to the valve stem consists of two parts, the lower sliding rod, which has attached to it the roller, rolling on the cam, and the upper part, *f*,

which is hinged to the lower part. A spring, acting through a pin on the projection of the lever *f*, ordinarily holds it in line with the part to which it is hinged. The lever *b*, pivoted from a support fastened to the crank-case, connects to the rod *f* by means of a link *d*. On the same shaft with lever *b* is another lever, which carries a roller at its lower end. This roller can be moved sideways on its shaft, and by this motion it is brought successively into contact with two cams on the cam shaft. These cams, through the intermediary of levers, throw

FIG. 1.—GENERAL VIEW OF ROCHET CAR.

FIG. 2.—PLAN OF FRAME OF ROCHET CAR.

the rod *f* out of line with the part to which it is hinged, and thus make it miss the valve stem, when it is lifted by the exhaust cam. The shifting of the roller is effected by the centrifugal governor. The water circulation is maintained by a pump, a large radiating coil being also fitted in the fore part of the frame.

Four forward speeds, ranging from 5 up to 30 kilometres per hour, and a reverse motion are provided. As already stated, the motor is in front and the power is transmitted through the conical friction clutch *I'I'* and the shaft *P* to the speed-changing gears in the case *F* (Fig. 2). The change gears of the Rochet vehicle are of a somewhat different order from those usually found in French vehicles. The gear case with the gears in place is illustrated in Fig. 6. The central gear wheel *A*, the shaft of which is seen protruding, is the driving gear, and is concentric

FIG. 3.—VIEW OF ROCHET MOTOR.

with the motor-shaft. At the side of this wheel, running loosely on the motor-shaft, is a disc *K³*, which on one face has projecting from it five short spindles, on which are mounted spur-wheels *K¹*, *K²*, *K³*, *K⁴*, *K⁵*. The last four of these, while being each of a different diameter to give the necessary variation in speed, are continually in gear with the wheel *A* on the end of the motor-shaft. The four wheels *K²*, *K³*, *K⁴*, *K⁵*, each have rigidly connected to one of their sides small spur-wheels *C²*, *C³*, *C⁴*, *C⁵*. Under the action of a lever, the disc can be rolled round the wheel *A* until any one of these small spur-wheels is brought into gear with the spur-wheel *B* on an intermediary shaft parallel with the motor-shaft. In this way any one of the four speeds can be quickly put in gear; for the backward motion, the spur-wheel *K¹*, driven through the train of wheels *A K⁵ C⁵*, is brought into gear with *B*. From the intermediary the power is transmitted through a bevel wheel to a similar bevel wheel on the differential shaft (Figs. 2 and 9), and from the latter to the rear road-wheels through the usual chain gear.

The vehicle is steered by a handle-bar *T* (Fig. 8), of which the left handle is bent upward while the right hand one is horizontal. The handle bar method of steering is claimed by the company to possess numerous advantages over the wheel; its management is more instinctive, its position indicates at once the

FIG. 4.—SECTIONAL VIEW OF ROCHET MOTOR.

angle of the front wheels, a thing of the first importance when manœuvring in close quarters. On the standard of the steering handle are two small handles working on notched segments. One of these acts on the governor of the motor and the other on the ignition, to vary the lead of the latter. Another and larger lever *U* acts on the speed-changing gears. To increase the speed the lever is moved forward, while a backward movement engages the lower gears successively and then reverses the vehicle.

At the driver's right is a brake lever *W*, which tightens leather-lined brake bands on two drums, one on each of the hubs of the rear wheels, after first having by the same movement disengaged the motor at the cone clutch *V*. This lever *W* is latched by a dog engaging a notched segment, so that the vehicle may be braked and the hand then employed for other purposes. There are two pedals, of which the left-hand one first disengages the motor and by further movement applies a brake on the differential. The right-hand pedal acts in precisely the same manner as the lever *W*, first disengaging the motor and then applying the rear wheel brakes. These brakes can therefore be applied either by hand or by foot, as most convenient. In an

FIG. 5.—DETAILS OF EXHAUST VALVE GEAR OF ROCHET MOTOR.

emergency both brakes can be applied at once. A third pedal, operated by the driver's heel, releases a latch governing the speed changes, and is always operated in connection with the lever *U*. Cycle type wheels are fitted, these being shod with pneumatic tyres. The Rochet car is made by La Compagnie Générale des Cycles et Automobiles, of Paris, and is being introduced into this country by Messrs. Friswell and Co., Limited.

THE RECENT PARIS-TOULOUSE RACE.

THE Sports Committee of the Automobile Club of France has at length issued to the public the exact net running time made by each of the finishing competitors in the recent Paris-Toulouse-Paris race. The preparation of this official return has been no light undertaking, for the passage of every racer through the dozens of controlled towns encountered *en route* had to be accurately timed, and a corresponding deduction made from the unadjusted figures standing to his record. To ensure absolute accuracy all this was done with an infinity of precautions, and the figures now quoted are quite beyond suspicion. In but one single instance are the placings affected by the deductions, and, as will at once be surmised, this relates to the positions held by Voigt and Pinson. The gross times gave Voigt a lead of 51sec. over his rival; but, now the reductions have been made, it is Pinson who secures second place after Levegh, and this is by a 49sec. margin from Voigt. This is a truly astonishing result over so great a distance as 1,348 kilometres (842½ miles), and affords another proof of the reliability of the Panhard cars. The two vehicles in question are identical, with the exception that Voigt's machine is provided with ball bearings, whereas bearings of the ordinary type are fitted to Pinson's car. In view of the closeness of the finish

Cycles.

Schrader ...	27	2	12	18	47	23	45	49	35
Cyrus ...	39	43	58	17	40	45	57	24	43

The average speeds per hour achieved by the competitors throughout the race were:—Cars—Levegh, 64 kil. 700 metres; Pinson, 60 kil. 815 metres; Voigt, 60 kil. 754 metres; Giraud, 58 kil. 800 metres; Antony, 50 kil. 300 metres; de Turckheim, 35 kil. 800 metres; Ravel, 32 kil. 800 metres; Brillie, 30 kil. 495 metres.

Motor-cycles.—Teste, 56 kil. 400 metres; Collignon, 49 kil. 100 metres; Bardin, 46 kil. 900 metres; Gasté, 44 kil. 100 metres; Gleizes, 37 kil. 100 metres; Fournier, 33 kil. 700 metres; Durand, 19 kil. 100 metres.

Voiturettes.—Renault, 44 kil. 100 metres; Schrader, 29 kil. 400 metres; Grux, 23 kil. 400 metres.

FIGS. 6 AND 7.—THE ROCHET VARIABLE SPEED GEAR. (See page 423.)

the organising committee decided to give the third man an equal prize to that taken by the second, so both Pinson and Voigt secure a silver medal and £240 in cash. The other placed men took the following awards:—

Cars 1, Levegh, £320 and a silver gilt medal; 4, Giraud, £160 and a bronze medal; 5, Antony, £120 and a bronze medal; 6, de Turckheim, £80; 7, Ravel, £40.

Motor-Cycles.—1, Teste, £80 and a silver gilt medal; 2, Collignon, £60 and a bronze medal; 3, Bardin, £40 and a bronze medal; 4, Gasté, £20; 5, Gleizes, £20; 6, Fournier, £20; 7, Durant, £20.

Voiturettes.—Renault, £160 and a silver gilt medal; Schrader, £80; Crux, £40.

The official times and placings are as follows:—

Name.	Cars.	1st stage.			2nd & 3rd stages.			Total.		
		67.3 kil. 500.			67.5 kil. 250.					
		h.	m.	s.	h.	m.	s.	h.	m.	s.
Levegh	10	11	11	10	38	58	20	50	9
Pinson	12	11	56	9	59	5	22	11	1
Voigt	11	58	0	10	13	50	22	11	50
Giraud	11	56	24	10	59	8	22	55	32
Antony	13	15	6	13	31	21	26	46	27
De Turckheim	18	5	57	19	29	39	37	35	36
Ravel	26	50	2	14	10	27	41	0	29
Brillie	23	34	54	19	55	14	43	30	8

The time made by Levegh, allowing for halts on both sides and corrected with regard to distances, is some fifteen minutes faster than the speediest train running between Paris and Toulouse. The performance made by Pinson on the return journey is even faster still, but it was accomplished in two stages, whereas the outward run to Toulouse was made without a break, and consequently much more trying both to man and motor.

MOTOR-CAR trips are just now a favourite amusement at Hastings. The vehicles run at frequent intervals between that resort and Bulverhythe, carrying full complements of passengers. A motor-car trip to Brighton was announced to take place on Tuesday.

It is stated that the Swiss Council of State has issued an order forbidding the use of automobiles throughout the territory of the canton of Grisons under penalty of fine and the confiscation of the vehicle. The automobilists in the district have lodged an appeal with the Chambers-General against the decree.

MESSRS. MARSHALL AND Co., of Manchester, inform us that they have recently adopted roller-bearings on their motor-cars, and that the results are giving great satisfaction, both from the point of view of hill-climbing capabilities and of increased average speed.

MOTOR-CARS ON THE CONTINENT.

(From Our Own Correspondent.)

The Ostend-Meet.

IN order to save automobilists the necessity of hurrying away from Spa before the close of the meet, the Ostend authorities have decided to postpone the date of their fixture until Saturday, September 1st. The programme remains exactly as originally selected, indeed it would be difficult to effect any improvements in this respect. Quite a caravan of motor-men will journey through from Spa on the 31st inst., and another party will leave direct for Ostend from Paris. The royal automobilist, the Shah of Persia, is already at the famous Belgian watering place, but apparently has no intention of using his lately acquired Serpollet cars before he returns to Teheran in the late autumn, for I understand that the vehicles will be dispatched direct to the capital of the Shah's domain.

For the Motor Cyclists.

HAVING already submitted to the Director of Customs a petition on behalf of the owners of motor-cycles and having had it favourably received, M. Ballif, the President of the Touring Club of France, has now brought the matter before the notice of M. Caillaux, the Minister of Finance, who, it is confidently anticipated, will regard it with favour. As all cyclists are well aware, a reciprocal arrangement exists between the Customs authorities of certain countries whereby members of various federated cycling clubs, such as the English "C.T.C." and the French "T.C.F.," can introduce their machines free into those countries, and it is to extend this right to motor-cycles that M. Ballif is now petitioning the Government. So many men now indulge in motor touring that the concession would be keenly appreciated, and M. Ballif and the "T.C.F." are to be heartily congratulated upon having initiated the movement. The Touring Club's work is by no manner of means confined to cyclists, but embraces automobilists, and the new sport has already good cause to be grateful to the "T.C.F."

New Records.

NOT since Bonnard's motor-bicycle performance, achieved on June 30th last over a route of 100 kilometres, had any new records been made for any distance or for any type of machine until the 12th instant, when new figures were set up for the 50 kilometre motor-tricycle and the 100 kilometre voiturette records. These performances were made on the Orléans-Salbris road, and were organised with the greatest secrecy; indeed, but very few Parisian automobilists had any idea that such an expedition was on foot. Thanks to these precautions the speed trials were successfully carried out without any interference by the authorities, and although all the attempts were not productive of fresh records, still in a couple of instances, as stated above, new figures were set up. Rigal was the successful performer in the case of the 50 kilometre motor-cycle record, and his time of thirty-six minutes for the distance will take a lot of beating. It represents a speed of 84 kilometres, or 52½ miles per hour! The previous "best" was Béconnais', made on July 17th last, and was four minutes slower than Rigal's performance. In the case of the 100 kilometre voiturette record Marcellin was the performer, and he knocked nearly three minutes off the time made by Cottureau in this year's Critérium des Voiturettes. The new figures are one hundred and two minutes, which is practically an average speed of sixty kilometres per hour. Loppart, who attacked Béconnais' record for 100 kilometres, can be heartily consoled with, for although he actually achieved better times the figures cannot receive official acceptance owing to a "contrôleur's" absence from his post during a portion of the trial. Hard lines for Loppart. The timekeeper was M. Gaudichard, who has so often held the watch for speed trials of this description.

Motor-Racing in Russia.

A HUNDRED verst automobile race was run near St. Petersburg on Saturday, the 4th inst. Seldom, if ever, had so much excitement been visible on the roads around the capital. The route lay from the Narva Gates along the Tsarskoe Selo road to Krasnoe Selo, as far as Strelna, forming a triangle of forty-one versts, which had to be covered twice, and winding up with a run direct to Strelna. There were three categories, namely, automobiles, voiturettes, and tricycles. Of course, the entries for the last-named were the most numerous. The Grand Duke Sergius Mikhaylovich presented the prize, a handsome dressing-case, for the automobile category, in which M. Barbet's carriage secured first place, covering the 100 versts in 3h. 57min. 20sec. M. Fomin won the voiturette race in 4h. 23min. 50sec. The tricycles made the best time, namely, 2h. 53min. 39sec., which was M. Dechamps' performance. M. Mikhayloff, who was second, took 3h. 1min. 2sec.

Motor-Cars in the Austrian Army.

MOTOR traction has been playing an important part in the Austrian army manoeuvres, and the experiments have excited much interest, as the locality near the Carpathian range of mountains is hardly the best for such trials. Twelve motor-vehicles on the Amédée Bollée system were in use, while the staff officers at headquarters were supplied with motor-cycles.

A Scarcity of Petrol.

M. PIERRE LAFITTE writes to the *Velo* deploring the universal lack of petroleum spirit prevailing along the French northern coast. M. Lafitte went to Cabourg to enjoy a week's touring, which has been brought to an abrupt and premature termination by a petrol famine. Automobilists have flocked to the Trouville and Deauville coast in such numbers that the supply began to run short in the district. Local dealers made application to the wholesale trade for further provision, but in vain. Meanwhile, hundreds of motor men are said to be stranded along the Normandy coast in despair being at unable to use brand-new cars of the latest pattern, and anxiously wondering how they will get back to Paris again.

A Race from Berlin to Aix-la-Chapelle.

A long-distance race is about to be run off in stages from Berlin to Aix-la-Chapelle. The start will take place at the Zoological Gardens in Berlin at nine a.m. on the 30th inst., Magdeburg, 142 kilometres, being the end of the day's journey; on the 31st Hanover, 152 kilometres, will be made for; on the 1st September Munster, 188 kilometres; and on the 2nd Aix-la-Chapelle, 206 kilometres, the total distance thus being 688 kilometres, or about 430 miles. The race, which is being organised by the German Automobile Club, of Berlin, and the West German Automobile Club, of Aix-la-Chapelle, will be divided into the following four categories:—(1) racing cars; (2) touring cars weighing more than 400 kilos and having engines of not more than 9 h.p.; (3) voiturettes of not more than 4 h.p. and weighing less than 400 kilos; and (4) motor-cycles.

A MOTOR-CAR trip took place a few days ago from the Grand Hotel, Newcastle-on-Tyne, to Harrogate and Leeds, the fares being 15s. and 12s. 6d.

THE De Dion Bouton British and Colonial Syndicate, Limited, 14, Regent Street, London, write us to the effect that the car upon which Mr. Eadie and two other gentlemen met with an unfortunate accident last week, through an axle breaking, was not a voiturette of Messrs. De Dion Bouton's construction. The latest type of the latter are stated to be of a very different construction to the car in question.

PARIS EXHIBITION NOTES.

(FROM OUR OWN CORRESPONDENT.)

(Continued from page 413.)

I DO not for one moment suppose that the reader of these notes will, when visiting the Exhibition, carry out my suggestion to first visit the Musée Centennial des Voyages et du Tourisine, for upon entering the automobile section his first thought will be for—Panhard. And it is very natural, for no matter what may be his nationality every automobilist regards the Ivry firm with something akin to reverence. Here in France the position of Panhard continues absolutely unique, and there are no real signs of its diminishing. In the racing world they may not now have matters all their own way as of yore, but the fact of their competitors winning a few races can have but very little effect upon the business of the firm. All classes of motor men are still willing to admit that for reliability no vehicle can yet be compared to those turned out from the Ivry factory, and the man who can pay the price does not hesitate long in his choice of a car. Their exhibition at Champs de Mars is in every respect worthy of the firm. First of all there is a "tonneau" wagonette, of which the carriage work has been executed by Jeantaud. Painted white, with broad red lining, red wheels, and red leather upholstery, this 8 h.p. car is very smart. It is fitted with "compound" tyres and carries a light awning. A "tonneau" of Rothschild construction comes next, and this vehicle is painted red, with fine yellow lines. Red leather upholstery, brass fittings, and yellow painted wheels combine to make a harmonious whole. Next upon the list is a brougham, built by Mülbacher, which carries the motor under the front seat. This beautiful carriage is painted black and green, with red lining and red wheels. It is constructed to carry four people inside. At the other side of the stand is a car fitted with a less costly class of carriage work. In shape it is a wagonette, and is upholstered in blue cloth. As compared to the other wagonettes shown it is not a graceful vehicle, the lines being stiff and harsh. The fifth and last carriage shown is a 12 h.p. car of truly magnificent proportions. I

cannot give it a name, for Labourdettes' design is absolutely original. First of all there is the motor in front, then comes a seat amply sufficient to carry three persons, all three being sheltered behind a glass screen, raised or lowered at will. This seat is upholstered in red leather. Then follows another movable glass screen, behind which are a couple of pivotted seats, which face in any desired direction. The space between these two seats permits of access to the spacious seats found at the back of the car, and which readily accommodate three people. The rear portion of the vehicle is enclosed at the sides, while from end to end stretches an awning. The rear seats are upholstered in brown corduroy, and the car is painted a rich red, lined yellow. It

is an exceptionally handsome vehicle, and certainly of unique design. A whole family might comfortably tour in the car for weeks together, as it is a veritable caravan. One other interesting feature of the Panhard stand is the table of racing records displayed, which date from the Paris-Bordeaux of 1895 to the events of the current year. And what a difference in speeds! Paris-Bordeaux, 1895, was won at an average speed of 20 kil.390 per hour, while in Pau-Peyrehorade-Pau, 1900, the winner made 70 kil. per hour, or practically three and a-half times faster than the champion's speed of five years ago.

The exhibit of M. Terrot, of Dijon, consisting as it does of but a single De Dion quadricycle, would call for no attention were it not for the attachment of a cooling apparatus to the motor of this machine. This apparatus outwardly has the appearance of a bent tube, and is fitted on to the lubricating hole of the base chamber.

It carries at its base another bent tube, through which is passed the lubricating oil to the chamber. The other extremity of the cooling apparatus is bent over the cylinder head. Now, when the piston ascends, a quantity of cool air is drawn into the cylinder and base chamber, from the walls of which it absorbs a certain quantity of heat. During the piston's descent this air is forced out, and so the operation is continued with every revolution of the motor. It appears to me that the only objection that can be urged against this plan is that it interferes with the proper lubrication of the pistons and cranks; but the inventor claims that the construction of the

FIG. 8.—ELEVATION OF FRAME OF ROCHET CAR. (See page 423.)

FIG. 9.—UNDERNEATH VIEW OF FRAME OF ROCHET CAR. (See page 423.)

apparatus renders the loss of lubricating oil an impossibility. Personally, I know of at least one automobilist who has worked a very similar plan with great success on a motor-cycle, and as his was a somewhat makeshift contrivance M. Terrot's perfected apparatus should give even better results.

MM. Teste Moret et Cie, of Lyons, show but one car, and that one is of a style far removed from that of their ordinary productions. It is a voiturette, tastefully painted in white and gold, and built in the Louis XV. style. Really artistic pictures adorn the panels on either side, and the upholstery, in a reddish tint of plush, is very pretty. A gold and silver water-cooled De Dion motor is attached to the rear of this wonderful vehicle, which never fails to evoke enthusiastic cries of admiration from the ladies, to whom, of course, it strongly appeals. The car is naturally only intended for advertising purposes; for, although doubtless capable of running well, its splendour would be too quickly dimmed were it permitted to join its brethren of the route, and career over muddy roads.

The Clément factories, at Levallois-Perret (Seine), have sent a large assortment of cars and cycles to the show, and the man who is on the look out for something thoroughly reliable at a moderate price cannot do better than give their machines a trial. First, we have a couple of "Krebs" voiturettes, built under licence from Panhards, a number of which are already to be seen running about Paris. The one is a two-seated car, while the second is built to carry three persons. A Clément voiturette fitted with a water-cooled De Dion is also to be seen, and then we pass into the motor-cycle class, represented by a quad and a

THE TURGAN-FOY VOITURETTE.

tricycle, both carrying De Dions. The remainder of the exhibit is made up of a variety of ordinary cycles.

The display made by MM. Turgan and Foy, of Rue Carnot, Levallois-Perret (Seine), consists of a couple of their well-known voiturettes, the one being belt and the other gear driven. The former system of transmission was that originally adopted by the firm, but the means employed for utilising the four speeds with which the vehicle is fitted is distinctly complicated, and I infinitely prefer their gear-driven car. Apart from the system of driving, the two voiturettes are practically of similar design. First of all we have a two-cylinder air-cooled motor, developing $4\frac{1}{2}$ h.p., placed on the fore part of the frame, and as this engine differs in many respects, both as regards construction and pose, from the ordinary type of petrol motor, a few brief details concerning it may not be out of place. The two cylinders are horizontal and are disposed end to end, the crank shaft passing vertically between them. The cranks are angled at 180deg., and the lower extremity of the shaft carries a horizontal fly-wheel. By this disposition the constructors claim to have largely overcome the vibration difficulty, and the absence of the usually-employed horizontal crank shaft certainly saves the carriage springs from the jar arising from each downward impulse of the piston. By the medium of two spur pinions, a toothed wheel of double the diameter is driven, and the shaft to which it is keyed governs by means of cams the exhaust valves and timing gear. The frame of the car is built up of steel tubes; the front wheels are pivoted, while the rear wheels are the drivers. In the case of the belt-driven vehicle the steering is effected by a wheel

placed on the right of the driver, whereas the other type of car is fitted with the ordinary inclined irreversible system. The firm also turn out motor-cycles, the motor usually employed being of $2\frac{1}{4}$ h.p., but if desired for racing purposes, an engine measuring 100 m.m. diameter by 100 m.m. stroke can be supplied.

(To be continued.)

CUSTOM AND THE MOTOR-CAR.

IF the horseless carriage, like the poor and the single-tax agitation, we are to have "always with us," it is to be hoped that we shall some day cease to miss the horse. That, however, cannot come about until some genius shall invent and persuade us to accept such forms of the new vehicle as will enable us to forget him. But in order to do that we must forget the vehicle that he drew—that is to say, we must have a vehicle whose difference from the old one consists in something more than its horselessness. Nearly every part of the one that we have has been constructed with direct or indirect reference to the animal that used to pull it, and fond recollection presents him to view as still pulling it.

Divorced from him it looks bereft, uncomfortable, and helpless. It offends the eye, shocks our sense of the fitness of things, and is a sore trial to the spirit generally. Probably, though, its horse-born features will remain in evidence for centuries after their origin is forgotten. Posterity will regard them as essential parts of the automatic scheme—will feel, for example, that without a "dash-board" the thing could not be made to go.

It requires generations for us to learn how best to do a new trick evolved from an old one. You shall not cast your eyes anywhere among the works of man without their resting on some "survival"—something that once had a purpose and a meaning, but has long ceased to have either, and is perpetuated by nothing but a stupid, unreasoning conservatism—a habit of continuing to do what has always been done. I could fill this entire newspaper with instances in point. Why have so many buildings watch-towers without watchmen, battlements from which to fight no battle, bastions loopholed for archers, and so forth? Go into a cemetery and observe the number of marble, granite, and bronze "urns." When cremation was the rule (most of us think it is a new fashion) real urns were used to hold the ashes of the dead. There are ashes no more, but the urns are there all right, and in explanation we say they are symbols. That word "symbol"—what a multitude of stupidities it covers! To-day a convenience, to-morrow a superfluity, the next day a symbol—such are the genesis and development of things most precious to the sentiments. But the days are ages long.

Not all survivals are "symbolic"; only such as touch the sentiments. Most are merely nuisances; but we go on making the thing, or doing the act, as diligently and gravely as if it were needful. The merchant vessel of to-day is frequently painted to look like a war ship with portholes for cannon. That is to scare away the pirates. The pirates have all left the high seas and gone into business on land, but that makes no difference; the traditions of the ship-painting art require the dummy portholes.

In England and several other European countries the railway coach is still so made and painted as to resemble three stage coaches in line. Why? Because in the mindlets of the first builders of railway coaches that form was associated with the most rapid locomotion they knew about and with the carrying of passengers. The builder of to-day has not ventured to alter it lest some appalling calamity befall. It cannot be too often repeated that man is of an intelligence but little inferior to that of the gods. He made the gods. So we shall doubtless have the automobile for a few centuries without material change of form—that is to say, crying out audibly for the horse. It is rather a pity, for it offers great opportunities to the artist. It could be made beautiful exceedingly. I have no designs to submit for rejection, further than to suggest a study of the prow of a Greek galley, or a Venetian gondola, with a view to emancipation from the hideous "dashboard."—AMBROSE BIERCE in the *New York Journal*.

CORRESPONDENCE.

150,000 MILES!

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In the report of a furious driving case in your issue of even date, my attention is arrested by the reported evidence of a "defendant" at Steyning. If the report is correct, this gentleman states that he covered 150,000 miles in the last eighteen months! Allowing 365 days in a year, and admitting, for the sake of calculation, that these eighteen months contained 548 days, this wonderful *chauffeur* must have done an average every single day of the last eighteen months of $273\frac{1}{2}$ miles per day! And yet he goes on to say that he has never passed a horse at more than six miles per hour!

We read the other day of a gentleman summoned on a 12 h.p. Panhard racer, coming down a medium incline at full speed, and who swore in a witness-box that he "did not know he was going more than twelve miles per hour"!

We are familiar with the erratic evidence of ignorant and over-zealous police-constables; but don't let us *chauffeurs* get a name for this sort of thing, or the innocent will have to suffer with the guilty. If you have done wrong, be a man and say so. Don't whine!

Yours truly,

Sowber Gate, Northallerton, J. ERNEST HUTTON.
August 18th, 1900.

QUESTIONS RE MOTOR-CYCLES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Having read with interest Mr. Smith's letter of the 4th August, and also having been the possessor of a Beeston "quad" with a similar defect to that mentioned, I should like to explain how the readjustment was carried out. In my machine the lever was secured to the right side of the handle bar, and was utilised for releasing and keeping open the exhaust valve, besides applying the brake (the only one fitted, by the way). The unfortunate part was that, in this case, the brake totally failed to act. On examination the tapped rod attached to the band of the brake—which was in connection with the above-mentioned lever—was found to be insufficiently screwed through the metal block attached to the end of the steel band. It was found necessary to disconnect the lever rod and give the same several right-handed turns before the brake worked to my entire satisfaction. I should therefore recommend Mr. Smith to detach the rod in question and go through a left-handed twist performance.

Yours truly,

7, Loudoun Road, St. John's Wood, N.W., W. G. BELL.
August 13th, 1900.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Your correspondent "Novice" could obtain what he desires by means of a Bowden brake wire connecting the throttle valve crank to one of his handle grips. As he seems to use an Ariel tricycle, I presume that it is the right hand grip which switches the current on and off; he should then have a Bowden brake wire worked by the left handle grip. I scarcely think, however, that the result will be so satisfactory as he seems to expect, and would suggest that he should substitute the more liberal use of the brake and the exhaust valve opener. I found no difficulty whatever in fitting Messrs. Wilkins and Boon's exhaust valve opener to my Ariel tricycle, and it worked perfectly during the 1,000 Mile Trial.

168, Clerkenwell Road,
London, E.C.,
August 18th, 1900.

Yours truly,

A. J. WILSON.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—With reference to "Novice's" query of a device for more effectually controlling the engine from handle-bar of a tricycle or "quad," the very best and simplest idea is in my mind the Bowden wire affair, as supplied and fitted by Mr. Boon.

By this very simple arrangement compression is quite done away with for starting the motor with pedals and for running down a steep hill after shutting off spark and mixture, thus greatly helping to cool the engine and economising current and petrol. It also does away with the hissing and spitting compression tap by holding the exhaust valve wide open, thus enabling one to start easily and silently or run past a restive horse without noise. I believe Mr. Edge had one fitted to his 6 h.p. De Dion trike, which greatly facilitated the control of this speed instrument.

Yours truly,

A. E. J. STEELE.

PNEUMATIC TIRES AND PUNCTURES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Re placing leather belting between the inner tube and outer cover of pneumatic tires; I should advise your correspondent, Mr. W. Vanderbyl, not to try it. I recently have seen a bicycle treated in this way—a hogskin band was placed in the outer cover—and the inner tube was literally sawn almost in halves by the leather. There must also be a great loss of resistance.

Yours truly,

R. A. COBB.

29, Dalby Square, Margate, August 12th, 1900.

FROM LLANDUDNO TO EALING.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—It may interest you to hear of a successful run made by myself and friend this week. Leaving Llandudno at 3 p.m. on Sunday, we ran through to Shrewsbury, arriving at 9 p.m. Leaving Shrewsbury on Monday at 8.20 a.m., we reached Ealing before midnight; distance, 260 miles. The car was a De Dion voiturette, and excepting having to take off cylinder to regain cotter pin of inlet valve, which had fallen through the port, our troubles were slight.

Yours truly,

T. B. PERCY.

Hotspur Lodge, Ealing Common, W.,
August 18th, 1900.

IRISH ROADS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I cannot agree with Colonel Magrath that my letter on this subject is calculated to do harm. The County and Rural Councillors in Ireland are the people who have the power in their hands as regards the roads, and they are not likely to see the *Motor-Car Journal*. Even if they were, I think I had made it perfectly clear in my letter that we possess roads both good and bad, and, in fact, my object in writing was to make intending purchasers institute enquiries as to the localities which would suit best for touring.

With all due respect, I think I have more experience of the roads in Ireland than Colonel Magrath, who lives in the county Wexford, where the roads are notoriously bad. My experience has embraced every county in Ireland; in fact, I have cycled in this country close on 90,000 miles.

That the county Wexford roads are, as a rule, exceedingly bad, I quite admit, but I join issue with Colonel Magrath in his statement that all Irish roads are covered with loose stones, and that they are absolutely unfit for use in the winter. During our recent tour of 700 miles we often traversed very long stretches of road without meeting a single loose stone, and, despite the weight of our cars, our tires came back in perfect order—there was hardly a mark on them. I have cycled on some of these roads in the middle of winter, and have found them in most cases quite free from loose stones, and I have ridden on dry smooth surfaces two hours after rain.

I think Colonel Magrath's letter, which comes directly under the notice of English motorists, is calculated to do considerable harm to this country, in that it will prevent tourists from travelling here. As I have before stated, some of our roads are execrable, but, on the other hand, others are very near perfection.

It was with the object of impressing this on your readers that I wrote my letter, as I did not wish them to come to this country and return disappointed through not having proper routes ketched out for them. I am quite prepared to do the needful in this direction for any tourists, and I might state that I shall not send them to the Co. Wexford, from which Colonel Magrath has derived his experience.

Yours truly,
R. J. MECREDDY.

Dublin,
August 21st, 1900.

THE SIMPSON-BODMAN STEAM VEHICLES IN AMERICA.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—You will be interested to hear that Mr. W. L. Bodman, of Messrs. Simpson and Bodman, Manchester, England, has severed his connection with that firm and joined this company in order to develop the Simpson-Bodman system for road transport in the American States. At present we are makers of a light two-passenger car, but it is our intention to construct a full line of steam vehicles from this size up to the heaviest that Mr. Bodman thinks advisable for use on American roads, and to shortly proceed to heavy and systematic manufacture. We made our arrangements with Mr. Bodman after careful tests in Lancashire, and consideration of other and competing systems, as being the only system that was practical for use on the heavy and uneven road surface and variable climate and season prevalent in the United States.

Yours truly,
MILWAUKEE AUTOMOBILE CO.

Milwaukee, U.S.A., August 8, 1900.

THE RENAULT VOITURETTE.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I am surprised to see in your issue of the 18th a letter signed by Messrs. Renault Freres, of Billancourt, stating that Messrs. Friswell are not agents for their cars. I, Harry Farman, have been appointed, and hold a contract for the sole representation of the Renault cars in England, and this, for a consideration, I have turned over to Messrs. Friswell (which I have the right to do), who now have the exclusive right of selling these cars in England. Messrs. Renault cannot import these cars into England, and if any of your readers do import them I should be very glad to hear of it.

25, Rue de la Paix, Paris. Yours truly,
August 20th, 1900. HARRY FARMAN.

A MEETING of the Union of German Automobile Clubs is to be held in Berlin on the 29th inst.

THE Caledonian Motor-Car and Cycle Company, Ltd., have furnished the Aberdeen *Free Press* with a new motor delivery van, in place of the one destroyed in the recent fire in their premises.

THE other afternoon a somewhat serious street collision occurred in the Old Christchurch Road, Bournemouth. Just as a motor-car was proceeding down the road a wagonette from Mastrick Hall, Branksome, proceeding in an opposite direction, came out a little way from behind a brewer's dray. The front off wheel of the motor struck the hind wheel of the wagonette, knocking off both wheels. The occupants, however, escaped uninjured.

A RACE was recently held under the auspices of the Allgemeine Radfahrer Union and l'Automobile Club d'Alsace-Lorraine. The route was Strasbourg and return *via* Kehl, Dillingen, Rheinau, Boofzheim, and Plobsheim, a distance of fifty-six miles. The following were the results:—Class 1, Racing Vehicles: 1. Baron A. de Turkheim, of Lunéville, 1h. 28m. Class 2, Tourist Vehicles: 1. Max Schultzenberger, of Strasbourg, 2h. 12m. Class 3, Voiturettes: 1. E. Kraenker, of Audincourt, 1h. 44m.; 2. E. Benz, Mannheim, 2h. 3m. 30s. Class 4, Motor Cycles: 1. Dublon, Mannheim, 2h. 9m.; 2. Baron Hirsch, Paris, 2h. 20m.

THE FAHNENFELD-STADLER IGNITION TUBE.

A SOMEWHAT novel ignition tube has lately been devised, and is now being used by two Austrian sportsmen—Herr Anton C. von Fahrenfeld and Herr Ernst Stadler von Wolfersgrün, of Laybach.

In the new device the property possessed by some gases of becoming ignited by contact with sponge platinum or platinum shavings is utilised. The igniting tube 1 is connected in the ordinary way with the explosion-chamber 2 of the motor, and surrounding the igniting tube is another tube 3 of the same material as the igniting tube (platinum), while the space between the two tubes is filled with platinum shavings 4. The igniting tube is closed at the end remote from the explosion-chamber; but the outer tube is open at both ends. Around this outer tube is a sleeve 5 which is screwed into the wall of the engine, and is provided with a projecting nut portion adjacent to the wall. This sleeve has in it two openings 6, through which access may be had to the outer tube, and in the nut portion there is provided a number of radial passages 7, through which the space between the igniting tube 1 and the outer tube 3 communicates with the atmosphere. The feed-pipe 8 for the explosive mixture is screwed into the front end of the inner sleeve 5 and opens into the annular space

FIGS. 1 AND 2.

filled with platinum shavings between the igniting tube or pin 1 and the outer tube 3. Over the inner sleeve 5 is arranged another sleeve 9, which is guided upon the feed-pipe 8, and held in place by a screw-thread on the inner sleeve 5. To set the apparatus into operation the outer sleeve 9 is pushed back (Fig. 2), and the outer tube with the platinum shavings in it is then heated up by a suitable lamp through the openings 6 in the inner sleeve 5. The combustible mixture intended for the heating of the igniting tube 1 is then admitted thereto through the feed-pipe 8. The mixture on reaching the platinum shavings 4 ignites and burns, and the products of combustion pass to the apertures 7, and escape through them into the open air. When the outer tube 3 has been sufficiently warmed by the external flame for the platinum shavings to heat the entering combustible mixture to the ignition temperature, the external flame is removed or turned off, and the outer sleeve 9 is pushed over the inner sleeve 5 to protect the outer tube 3, and screwed up thereon against the projecting nut portion. A writer in *La France Automobile* states that he has used the new ignition arrangement on a 7 h.p. car for some months with very satisfactory results.

"W. P. W." is referred to the work on "Horseless Vehicles," by Mr. Gardner D. Hiscox, just published by Messrs. Sampson Low, Marston, and Co.

MOTOR-TOURING IN AMERICA.

MR. GEO. F. FOOTE, of Ithaca, New York, has sent the following interesting account of a recent motor tour in America to our contemporary the *Horseless Age* :—

"At 1 p.m., Saturday, June 16th, the Hon. E. C. Stewart and myself in my Winton motor-carriage started from Ithaca on a journey East. We were accompanied by Mr. Samuel Howe, of Cornell University, and his friend, Mr. S. M. Vauclain, jun., in the former's Winton carriage. Our first stop was at Cortland, 22 miles distant, which we reached in an hour and an half. We found the roads in fair condition, but passed through a very hilly country, some of the grades taxing our cars to their utmost. At Cortland we stopped to oil our machines and put in a fresh supply of water. Between Cortland and Truxton we met with our only mishap on the trip. As we rounded a curve about three miles this side of Truxton, we came in sight of a carriage containing a woman and child about one-eighth of a mile distant. The woman became very much excited and rattled at our appearance, and reined the old family horse around in great haste, spilling herself and grandchild into the ditch. The top of the buggy struck the fence and rebounded back on to its wheels, allowing the old horse to jog away down the road out of sight. The ditch being about three feet deep, the sudden disappearance of the woman and child made our hearts palpitate in a rather unpleasant manner. On riding up, we were greatly relieved to find that they were not seriously injured. After gathering up the lady's effects, I took her into the car beside me, and the Senator was pleased to play footman for a mile or so. Mr. Howe, who was about a mile in the rear at the time of the mishap, came up and took charge of the girl, and we proceeded on our journey. At a farm house, about two miles below, we found the family horse and buggy in possession of the owner of the place, and on our nearer approach the horse showed no fear of the machines, which convinced us that the woman was at fault for the accident rather than the horse. We found that she was some five miles from her brother's, whom she was on the way to visit, and as she was somewhat nervous from the shaking-up, we suggested that they remain at Truxton over night, and continue the journey the next day. We employed Mr. Farmer to drive the horse to the hotel at Truxton, and we delivered our passengers at the same destination. After expressing our regrets for the accident, and settling for their entertainment until morning, we continued our journey to De Ruyter, some ten miles away, where we took supper. At this point Senator Stewart returned to Ithaca, and my son, who had come up by train, joined us. We pushed on to Cazenovia, seventeen miles away, to spend the night, making a run of sixty miles in about five and a-half hours, which we thought very good, taking into consideration the condition of the roads and the hilly country we passed through.

"At nine o'clock the next morning we left Cazenovia for Richfield Springs, passing over some of the poorest roads encountered on our journey. The farmers, unfortunately for us, had been working them, plowing as they do along the ditches and throwing the sods into the middle of the road; and it was bump, bump, bump from 9 a.m. until 3.30 p.m., and both Mr. Howe and myself were relieved to reach Richfield Springs without any break-down. This is what is called the old Cherry Valley turnpike, and in taking this road instead of going from Cazenovia north to Syracuse, and so on down the Mohawk Valley, we expected to save about twenty miles. You can rest assured that after that day's experience we made up our minds that we would give the Cherry Valley turnpike a wide berth in the future. After tea we consulted our maps and decided to leave this route and go to Fort Plain, and so on down the Mohawk Valley to Albany. We had a refreshing night's sleep, arose early, gave our machines a thorough overhauling and cleaning, breakfasted at 6.30, and left Richfield Springs at 7.30 for Fort Plain. We had a delightful run through a wild country, over good roads, to Fort Plain. From that place we continued our way down the valley of the Mohawk through Herkimer, Little Falls, St. Johnsville, Fonda, and Schenectady, arriving at Albany about five o'clock in the afternoon. From Fort Plain

to Schenectady we found very good roads, beautiful farms, and fine scenery. It was very amusing to have the New York Central trains go by us, the engineers saluting us with three whistles. At times we would come up with freight trains, and where the roads were good could hold our own with them. In places I think we travelled at the rate of eighteen or twenty miles per hour. From Schenectady to Albany, seventeen miles, we followed the old turnpike road, which was in very bad condition, the same being in places from six to eight inches deep, which necessitated slow progress. Mr. Howe and friend having decided to remain in Albany for a day or two, we left their genial company Wednesday, at twenty minutes to five a.m., and made a good run to Hudson, forty miles by the route we took, in two and one-half hours. At Hudson we stopped for breakfast and sat down to a meal fit for the gods, with appetites whipped to a keen edge by that delightful ride in the exhilarating air through the foot-hills of the Catskills.

"Leaving Hudson at nine a.m., we passed through the pretty villages of Burden, Manorton, Red Hook, Rhinebeck, Staatsburg, and Hyde Park to Poughkeepsie, over what I believe to be the ideal roads of America for automobiling. Some of our fastest time was made over these roads, and at times we attained the speed of twenty-two miles per hour for short distances. The run from Hudson to Poughkeepsie was made in two hours and fifty minutes; distance registered on our cyclometer forty-three miles. The views of the Catskills from the east side of the Hudson are superb and long to be remembered. After an hour and a-half rest, proper attention to the inner man and a good feed of oil to the iron horse, we left Poughkeepsie, passing through Fishkill, climbing the mountains between Garrison and Peekskill in good shape, and arriving at Sing Sing at five p.m., making a day's run of 125 miles. After stopping over a day with friends at Sing Sing, we made the run of seventeen miles to Greenwich, Conn., by way of Tarrytown, White Plains, and Port Chester, in an hour and a quarter.

"Our return was over the same route to Albany, from Albany to Saratoga Springs, Saratoga Springs to Amsterdam, and so up the Mohawk Valley to Syracuse, and from there to Ithaca. Distance covered, 450 miles from Greenwich. This ended one of the most delightful trips it has ever been my pleasure to take."

A KRIEGER ELECTRICAL VICTORIA.

THE accompanying illustration shows an electric victoria on the Krieger system, displayed at the Paris Exhibition, by Messrs. Guet and Co., of Paris. The body is of the Victoria pattern, painted blue, lined with yellow, the under-carriage blue, picked out with two broad lines of yellow. The accumulators weigh 9 cwt., and are of a capacity sufficient to run the car forty-five miles on one charge. The maximum speed is

fifteen miles per hour. The diameter of the wheels is 41½ inches and 33½ inches. The body is hung on elliptic springs in front; at the back there are side and cross springs. The wood wheels are shod with pneumatic tyres, the weight of the vehicle complete being given as 26 cwt. We are indebted to *La Carrosserie Française* for the illustration.

THE DEVELOPMENT OF THE MOTOR-CAR.*

WITH the recent advent in force of motor-vehicles, under their various synonyms of horseless carriage, automobile, autocars, and motor-cycles, in a list in which the roots auto and moto enter into many names designating the specialities of manufacture in Europe and in the United States, comes the search by the curious to find the true history of progress in the development of self-propelled vehicles. Wheels as a rolling device have been in use for more than four thousand years with oxen and horses as their propelling power for transportation. The only improvement during the past four hundred years has been in the art design of the vehicles, and only during the past two centuries has thought been given to other means or powers of vehicle propulsion. The spirit of invention and improvement seems to have taken a movement among thinking minds in the fourteenth century and was thus early expounded by that philosopher in mechanics, Roger Bacon, in the following prophetic words: "We will be able to construct machines which will propel ships with greater speed than a whole garrison of rowers, and which will need only one pilot to guide them, we will be able to propel carriages with incredible speed without the assistance of any animal, and we will be able to make machines, which, by means of wings, will enable us to fly in the air like birds."

The first indication of the application of a mechanical device for the propulsion of vehicles seems to have begun in the sixteenth century in a vehicle propelled by springs, built in Nuremberg, by Herr Johann Haustach. The spring motor fever raged at times during the passing centuries, and seems to have culminated in the United States a quarter of a

century since as spring-stored power for street railway cars and vehicles. Its life for such work was short. Its true sphere is a lasting one through the centuries for the storage of power for time service. Wind sails for vehicle propulsion were a common sight in Holland away back in the palmy days of the republic, and have since been seen on the Western prairies, but no permanent success has resulted from this power for vehicle propulsion.

The first effort at propelling a vehicle by steam seems to have been made by a Jesuit missionary, Father Verbrest, in the thirteenth century, probably using the reaction wheel of the Heron type that had apparently laid dormant for more than a thousand years. It was a steam-propelled vehicle, with a motor of the reciprocating type, that made its advent with the early progress of the steam engine for power purposes that was the forerunner of the thousands of self-propelled vehicles that have, as it seems, sprung into useful operation during the last decade of the nineteenth century. Steam traction vehicles for haulage, for drays, for ploughing, and for passenger service have advanced steadily in Europe and in the United States, even extending to many other countries. The advent of the internal combustion motor soon gave a new phase to the self-propelled vehicle, and

*Abstract from introduction to Mr. Gardner D. Hiscox's work on "Horseless Vehicles, Automobiles, and Motor-Cycles." (London: Sampson Low, Marston and Co.)

gave a further impulse to its use as a pleasure carriage. The electric motor and the storage battery seem to have followed in due time to form the triad of powers that will give the horseless vehicle all the probable elements of success in every avenue of usefulness. The gasoline motor was first used for vehicle propulsion with success about 1888, but was proposed at an earlier date by Lenoir in France. The electric motor and storage battery soon followed, and came into use within the last decade of the nineteenth century. The patents in the United States for motive power and running gear date back to the beginning of the century in small numbers, increased in the decades from 1860 to 1880, and in the last decade of the century swelled up to a total of about 275. The earlier patents that expired previous to 1886 covered nearly all the essential features of the present construction. It appears from published data that in Europe there are now well over 7,000 owners of automobiles. Many of these own more than one vehicle, so that perhaps the number of vehicles could be put at 10,000. Of the 7,000 no fewer than 5,600 are in France. The general idea has been that in France the interest was centred in Paris, but this is erroneous, there being of the 5,600 no fewer than 4,541 scattered all through the departments. No such figures as these are at present obtainable for the United States, and if we put the number of automobiles

in America at 700 it will probably be an exaggeration. The number of makers actually at work or organising is probably more than 100. Fortunately for our credit as an inventive and enterprising nation, the first year of the new century ushers in with every promise of a great outburst of activity in the manufacture of automobiles of every description.

American constructors of gasoline motor-vehicles have, from the beginning, aimed to regulate speed through the motor and to reduce the speed gears to one or two, obtaining all

intermediate speeds by increase or diminution of the charge. In many of the French and American vehicles intermediate speeds are obtained by varying the tension of driving belt or other friction devices, and it is to be noted that the very latest French construction tends in the same direction as our own, viz., towards speed regulation by the motor. This tendency is universal, and it is only because the necessity of striking out in that direction was appreciated in the United States from the beginning that American constructors to-day may be considered as far, if not farther, advanced than their competitors in other countries where automobile experience is of much older date. When the speed changes in gasoline vehicles are under consideration, it should also be remembered that the momentum of a vehicle in motion always serves to efface all abruptness in the transition from a higher speed to a lower one or the reverse.

Steam seems to have taken the lead as the source of power for the horseless vehicles in England and France, with varying success, dragging slowly along with the progress of the steam engine for nearly a century, yet hampered by popular and governmental prejudice, obstructive laws and bad roads, which even in this enlightened decade has not been entirely cleared away. Official restrictions are still retarding the progress of the automobile in the United States; but are fast disappearing in Europe. During the past half century, the improvement of common roads has made great progress in France, Germany and

FIG. 1.—GENERAL VIEW OF "MIGNONETTE" VOITURETTE. (See opposite page.)

England, so that at the present time France has taken the lead in good roads and is equally in the lead in the manufacture of automobiles.

In England the agitation in the interests of good roads started more than a half century since, with only steam traction interest as the principal mover. Single-handed it battled for road improvement with but slow progress against popular prejudice and obstructive regulations and laws. The advent of the explosive and electric motors for vehicle propulsion added other and powerful impulses in the agitation for good roads, and with the pressure from the vast bicycle interest the quadriad of forces has come together with a combined power that will, we hope, make road improvement a foregone conclusion and a necessity in this and all other countries of progressive instincts. With good roads in the United States the automobile industry should soon forge to the front in legitimate activity.

France has so far taken the lead in the development of the automobile as a pleasure carriage. The reason for that is not far to seek. Paris, where the automobile is carrying everything before it, is in a superlative degree the city of good roads. Asphalt pavements, kept in perfect order and smooth as a billiard table, offer tempting inducements to automobile constructors and riders. Every variety of design and device for self-propulsion can be tested under the most advantageous conditions. If easy running, with good loads and high speed, cannot be attained on the Paris boulevards, then it is impracticable anywhere. Prizes have been offered to stimulate invention, and races arranged to test the devices offered.

To a great extent, what is true of Paris applies in nearly equal degree to the other large cities of France, and to the roads connecting them. Long runs can be made with the assurance of finding the perfection of good roads the entire distance. If, as is frequently the case, automobiles break down or fail from exhaustion of motive power under such conditions, it should be through no fault of construction or in ineffectiveness of the motive power when subjected to the test of long journeys, for this is common to all methods of travel. Following in the contest methods for invigorating constructive and perfect action in all parts of a vehicle and its power, the great contest in France in 1897 has been most prolific in the improvement of its weak point.

It is now fairly demonstrated that the horseless vehicle can be driven long distances over medium good roads at average speeds of fourteen miles per hour, and for touring parties this leaves the horse drag far in the shade for care and expense. The automobile fever has set innumerable inventors at work on motors of various kinds, while many *bona fide* companies have been formed for real work in producing automobiles for the market, and many more who are not inventors, or even manufacturers, that have organised away up in the millions for apparently the sole purpose of foisting upon capitalists a worthless stock.

There seem to be but three kinds of motive power that are taking the lead, viz., steam, internal combustion, and electric motors, each of which has its adherents or is specially suited to its own sphere of action or special field of usefulness. As for compressed air, the radius of action for road vehicles is somewhat limited, and although it has been tried in France and some experiments made in the United States, it has not as yet made much progress. Carbonic acid gas has as yet failed to give satisfaction, owing to the great sacrifice of pressure from its liquid state required to bring it within the limit of the working strength of a motor. Acetylene gas is somewhat expensive, and, although but slightly experimented with for vehicle power, it is yet to be developed as to its radius of usefulness in automobile work. Liquid air is out of the question for motive power.

(To be continued.)

MR. ROWLAND WINN informs us that he has now taken possession of new premises at 13, Cookridge Street, Leeds, where he has installed a plant to enable him to undertake repairs of all kinds to motor-cars and cycles.

DR. ORFORD, of Pontefract, is one of the latest members of the medical profession to adopt the motor-car, he having chosen a Marshall car. The vehicle was driven to Pontefract by road on Friday last, and with three persons up made a very successful run.

THE "MIGNONETTE" VOITURETTE.

MESSRS. WEHRLE AND GODARD DESMAREST, of Neuilly, France, have sent us a photograph of the "Mignonette" voiturette, which they have recently introduced, and which is reproduced herewith in Fig. 1. The car, which has seating accommodation for three persons, is provided with a 3 h.p. water-cooled motor—either a De Dion or Aster, as desired. It is fitted with electrical ignition, the carburettor being of the Longuemare type. The engine is located in the rear of the frame, and is geared direct to the differential on the rear axle. Three speeds forward and a reverse motion are available; the gear wheels, which are continuously in mesh with the differential, work in a dust-proof oil-containing case. A friction clutch, operated by a foot pedal, is provided on the motor shaft, while there is also a special device which acts on the exhaust valve when the clutch is thrown out to prevent the motor "racing." Steering is controlled by an inclined hand wheel, on

FIGS. 2 AND 3.—ELEVATION AND PLAN OF "MIGNONETTE" VOITURETTE.

which is fitted the current-breaker, the handles controlling the mixture and the sparking being fitted on the steering pillar. The variable-speed gear is controlled by the handle at the side of the car, while a foot pedal actuates a band brake on the differential drum. Either wood or cycle-type wheels, shod with pneumatic tyres, are fitted, while the body, which is spring-suspended at both front and rear, is constructed largely of aluminium. As will be seen, all the propelling gear is entirely concealed, thus giving a very neat and finished appearance to the car. It is claimed for the motor that the explosive mixture is ignited at the moment of maximum compression, thus obtaining the greatest result from the explosion, which acts directly on the piston.

AUTOMOBILISTS passing through Warwick must take care not to exceed the legal pace, for at the close of the business at the Borough Police Court, on Monday, the Mayor asked the police to endeavour to prevent the drivers of motor-cars going through the streets of Warwick at such a rapid pace as was their habit. On Saturday night he had been nearly run over by one. He had no opportunity of getting to know the driver's name, for the occurrence so unnerved him that he could scarcely see the vehicle pass.

FURIOUS DRIVING CASES.

MISS VERA BUTLER answered, at the West London Police Court, on Monday, to a summons at the instance of the police for driving a motor-car at a greater speed than was reasonable and proper. Police Constable 191 B said that defendant drove into Redcliffe Gardens, Kensington, from the Fulham Road at a speed exceeding twelve miles an hour. A horse became restive owing to the noise the car made in its progress, finally overturning the van to which the animal was attached, and throwing the occupant into the road. On behalf of the defendant, who, it was stated, held a certificate for efficiency in the handling of motor-cars, it was contended that she was not travelling at a greater speed than seven miles an hour, but Mr. Walter Hay, a gentleman residing at 16, Redcliffe Gardens, corroborated the opinion of the police officer. He added that when the defendant passed him, she was going fourteen miles an hour. Mr. F. H. Butler, father of the defendant, said he was with her on the occasion in question. He asserted with every confidence that the car was not being driven more than seven miles an hour. Mr. Rose was satisfied the lady was going too fast, and imposed a penalty of 40s., with 2s. costs.

At the Darlington Borough Police-court, on Tuesday, Mr. Wilson Hall, of High Terrace, Darlington, appeared to answer two charges of breaking the Highways Act (Locomotives), one being that he was travelling at too great a speed, and did not give audible warning of his approach.—Mr. R. M. Wilkes conducted the prosecution on behalf of the police, and Mr. T. M. Barron defended.—Mr. Wilkes stated that on Wednesday, August 8th, at about mid-day, the defendant was driving a motor-car from the direction of Cockerton to Northgate. Whilst going round the corner from Prospect Place into Northgate, near the York City and County Bank, he travelled at such a speed, without giving notice of his approach, that had it not been for the skill of one lady who was with another lady a serious accident might have occurred. Thomas Arthur Johnson, tramcar driver, detailed that he was driving his tramcar in the direction of the town, and when near Fox's the motor-car came round the corner on to his track and he had to pull up a little to let the car get to its own side of the road. Mr. A. Hill, manager of the Imperial Tramways Company, said he heard the sound of the horn of the car and later he saw it travelling at about eight miles an hour along Northgate. It would have gone into the car if his driver had not pulled up. Miss Hopkins and her mother detailed being almost run over by the motor-car. Mr. Barron, in his defence, said one of the charges was that of not having sounded a horn in Bondgate. The evidence for the prosecution had disposed of that charge. Major Hill had heard the horn sounded as he came round Bondgate corner, and on that score he asked for that charge to be dismissed at that stage of the proceedings. The Bench decided to hear the whole of the case before giving a decision. Mr. Barron said he had witnesses who would prove that the horn was sounded near Tanfield's shop and again near the Monument. There were three persons in the car, but he could only call two of them as one was away on a business engagement. The motor-car was only geared up to eight miles an hour when running on top speed. The horn, which was a new one, was sounded repeatedly.—Mr. Hall regretted any inconvenience which might have been caused to any one by his presence. The defendant was also called, and denied that he was travelling at a greater speed than four miles an hour round the corner, and he stated that he sounded the horn all the way from Tanfield's shop to the Bank. The Bench retired to consult, and upon returning into Court the Mayor announced that the charge of failing to sound a horn would be dismissed, but that in the other a fine of 10s. and costs would be imposed.

ACCIDENT AT MARGATE.

A SERIOUS motor accident occurred on the front at Margate shortly before ten o'clock on Wednesday morning. Mr. Avery, of Oakleigh Court, Windsor, was driving his car past the South-Eastern railway station, when the front wheel skidded on the lines which have been recently laid for the new electric trams. The road had just been watered and this rendered it slippery. The car, which was travelling at a good speed, capsized with a crash, and Mrs. Avery and her little boy, who were in the car, were flung heavily out of the vehicle into the roadway, while Mr. Avery and the car attendant had exceedingly narrow escapes. Mrs. Avery was taken from under the car in a semi-conscious condition, with a bad cut on her head and greatly shaken. She and the little boy, who was also slightly hurt, were taken into the railway station waiting-room where they received medical attention.

CABMEN OBJECT TO MOTOR-CARS.

At the Hereford County Court last week Mr. James Tudor Hereford, of Mordiford, sued John James, cabman, Hereford, for £3 damages caused to a motor-car. Mr. Corner, appearing for plaintiff, said that the latter was the owner of a motor-car, and on June 12th last he rode it into Hereford. He was going away by a train, so he left his motor-car with Mr. Rough, cycle engineer, with an arrangement to meet him with it at the station on his return in the afternoon. Subsequently Mr. Rough went in the car to Barr's Court Station, accompanied by his son. There was a tremendous dislike by cabmen to motor-cars, and defendant used some very foul language towards plaintiff, and deliberately drove his cab against the motor-car. One wheel of the cab lifted up the motor-car,

which was damaged to the extent of £3. It was marvellous that Mr. Rough was not injured. Mr. Rough, Mr. P. Skelton (Catford), and George Rough (son of Mr. Rough), bore out Mr. Corner's opening statement.

The defendant said that he was at the railway station plying for hire, when Mr. Rough drove up with his motor-car and stood by a bus. When one of the cabs drove away Mr. Rough went into the place where it had been standing, and as it was his (defendant's) turn he should have taken the place where Mr. Rough was. Two ladies were calling witness at the door of the station, and as he went to pass the motor-car, the hind wheel of his cab just touched the front wheel of the motor-car.

His honour said this was a serious case. Evidently there was a "dead set" against the motor-car by the cabmen and busmen at the station. He had no doubt about that, and it was his duty to hold the law evenly amongst all parties. Motor-cars had a right to be on the road, though perhaps a good many people, especially cabmen and busmen, disliked them. One was aware that when new things came up they were abused for a good many years, until they became common, when no one took any notice of them. It happened so with the bicycle, and was happening now with the motor-car, and it might happen with anything in the future. There must be protection against any overt act of damage, and judgment would be given for the amount claimed and costs. The Judge added that although this was not law it was advice, namely, that he thought those who helped the defendant to abuse Mr. Rough should help to subscribe towards the costs.

AN OBSTRUCTION CASE.

MR. ALFRED H. GREGSON was summoned at Blackpool last week for causing an obstruction in Clarendon Park on the 20th July. Mr. C. W. Callis defended. According to the evidence of P.C. Swarbrick, the defendant's motor-car was left standing in front of the Imperial Hydro., and a crowd gathered round it. Witness went up to the defendant, who was sitting with a gentleman and two ladies on a seat at the opposite side of the road, and asked him to move the car away as it was an obstruction, when he replied, "I will if I like. I have never been taken down by a policeman nor never will be. I am a solicitor." Mr. Callis said there was not the slightest evidence that the car had proved an obstruction to anyone, and he therefore submitted that no case had been made out. The defendant was staying at the Imperial Hotel, and had arranged to go with Dr. Walker, who was also in the hotel and had a motor-car. Whilst waiting for Dr. Walker to come up he engaged in conversation with two ladies and a gentleman. Five minutes after the policeman had complained the car was moved away. The magistrates inflicted the nominal penalty of 1s. and costs.

Two different services of motor-cars are projected in the Charleroi district of Belgium—one between Charleroi and Trazegnies and one between Charleroi and Binche.

It is stated that the German Reichstag has just voted an appropriation of £7,000 for experiments with the use of automobiles in the army.

At the White Hart Hotel, Reigate, the proprietor is catering well for motorists, not only having petrol for motor-cars on hand but also being able to charge any electric cars that may happen to go that way.

THE Napier Motor Company, Limited, has been registered with a capital of £100, to carry on the business of electrical and mechanical engineers, smiths, founders, carriage manufacturers, etc.

At the last meeting of the Staffordshire County Council the clerk reported that he had received copies of the resolutions passed by the Ashbourn Rural District Council and the County Council of the Isle of Ely in favour of taxation of motor-cars. The chairman moved that the correspondence lie on the table, and this was agreed to.

THE British Motor Traction Company, Limited, has been registered, with a capital of £1,000,000, to adopt and carry into effect the following agreements:—(1) An agreement made between the British Motor Company, Limited, of the one part and this company of the other part; (2) between the British Motor Company, Limited, and H. J. Lawson, of the one part and this company of the other part; (3) with the British Motor Company, Limited, and J. Harris of the one part and this company of the other part; and (4) with the British Motor Traction Company, Limited, and S. F. Edge of the one part, and the present company of the other part; and, generally, to carry on in all or any of their respective branches the businesses of manufacturers of and dealers in motors, cycles, vehicles, ships, flying machines, etc.

THE Motor-Car Journal.

[No. 78.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

ONE of our contributors has been taking his holidays in the West Country—a fact which accounts for the many references to that delightful district during the past few weeks. While many people call the West of England the worst of England, those who know the country regard it as the best of England. Just now the roads are in very fine condition. The journey from Minehead to Exeter and to Torquay is evidently all down hill, while the scenery through Dunster and Dulverton, and with the banks of the Exe lining the road for many miles, is most magnificent. Torquay to Taunton is another very fine road, every hill having been negotiable on our M. M. Co.'s phaeton, although the C.T.C. boards are freely *en évidence*. One hill between Teignmouth and Dawlish is nearly two miles long and particularly stiff. From Taunton back to Minehead—which we had made our headquarters—*via* Dulverton and Exmoor, is a road that opens up beautiful country.

From Lynmouth Town.

AT Minehead it was impossible to obtain petroleum spirit, and, having used up our reserve supply, we had to journey by coach to Lynmouth. On the return, and notwithstanding the splendid horses used in the coach, the start was inaugurated by an hour's tramp from the Lyndale Hotel. During this walk the "passengers by coach" gossiped about things in general, and one matter in particular. That was the recent wonderful ride up Porlock Hill. Again aboard the coach the talk continued, and we discovered that another member of the Automobile Club and a relative of the member reputed to have made the wager in connection with Mr. Edge's famous ride were participating in the conversation on the feat.

The Porlock Hill Ride.

THERE is no doubt this performance has done good to the industry, for it is the one topic of conversation among sportsmen in the West. Much has been said and written with regard to the wager which is reputed to have incited the ride. We have heard it gravely stated that the wager was for £2,000. Generally it is thought to have been £25, which was, we believe, the correct amount.

Accidents in the West.

ALL motorists know that horses in country districts are a source of danger. Often their antics are ungovernable by the driver and troublesome to passers-by. The drivers are fond of attributing their special viciousness to motor-vehicles—an unfair and partial way of looking at things. For generally the horse is to blame. At Hey Tor, on Dartmoor, we have recently witnessed a nasty accident, in which no motor-car was in any way concerned. A lady on horseback was approaching a coach—a Jersey four-in-hand char-a-banc—when her horse bolted, and the

rider was badly thrown. Probably the tooting of the horn alarmed her animal. In the same week at Brixham—a pleasant fishing village in Tor Bay—two ladies were thrown from a carriage drawn by a pair of horses, which were frightened by a little boy running from the pavement into the road.

Coach Accident at Cheltenham.

A FURTHER instance of the alacrity with which accidents are attributed to motor-cars, is afforded by a serious accident occurring at Cheltenham on Wednesday night. A tourist coach on its return journey had reached the brow of a steep hill, when a passing motor-car is said to have frightened the horses. They bolted up the bank almost overturning the coach and throwing driver and guard to the ground. When the coach righted itself, the horses dashed down the hill, and collided with a tree on the roadside. The passengers on the top of the coach were thrown off, and four or five persons were seriously hurt, including Mr. Coyney and Mrs. Shenton, who each had three ribs fractured, and Captain Hunt, late of Brighton, who was badly crushed and bruised. Everyone must regret the accident, but none should use it as a reason for obstructing the extended use of the motor-car.

The Voiturette Competition.

THE results of the Concours de Voiturettes recently held in connection with the Paris Exhibition have just been made known. Out of eighteen vehicles entered, thirteen—two Renault, one Hanzer, one Georges Richard, three Outhenin-Chalandre, one Peugeot, three Gladiators, one Créanche, and one Fernandez—succeeding in completing the 800 kilomètres at an average speed of 25 kilomètres per hour. The award of the jury is as follows:—Category 1.—Two-seated voiturettes weighing, empty, less than 250 kilogrammes: Gold medal, Gladiator voiturettes, Nos. 12, 13, and 14; silver-gilt medal, Georges Richard No. 4. Category 2.—Two-seated voiturettes weighing less than 400 kilogrammes: Gold medal, Renault voiturettes, Nos. 1 and 2; silver-gilt medal, Outhenin-Chalandre, Nos. 6, 7, and 8; silver medals, Fernandez, No. 18, and Hanzer, No. 13; bronze medal, Créanche, No. 15.

To Luton and Bedford.

ON Saturday next, the 3th inst., the English Motor Club is organising a run to Luton, where tea will be taken at Windmill Road between 4 and 5 p.m., at the invitation of Mr. E. W. Hart, a member of the committee. Then the run will be continued to Bedford, where the headquarters for the night will be at the Swan Hotel. It is suggested that the run back to town on the Sunday should be by way of Hitchin and then through Warden, Ickwell and Biggleswade; but the details will be finally settled by those participating in the trip. In our issue of October 20th last we illustrated the Maypole still standing in the quaint old village of Ickwell, and referred also to the model village of Warden, where the cottages are in marked contrast to those at Ickwell. Of the attractions of

Biggleswade, doubtless the Ivel Hotel will be well appreciated. All motorists are invited to take part in the outing, and the route laid down should specially appeal to North London *chauffeurs*. The scenery is good and the roads in excellent condition, so that with fine weather a fair contingent should be formed for this northern run. Hitherto the southern district has received most attention, and motorists will probably be glad of this opportunity of seeing the other side of London. Perhaps a run through Epping Forest would also prove popular.

An Exchange.

OUR advertising columns last week contained an announcement to which we give the further publicity of our editorial pages. It read as follows:—"Wanted, motor car, carry two; exchange diamond pin and Humber safety or cash." As a rule those who want motor-cars pay in cash, and the exchange system has not yet been introduced to any great extent. It would be interesting to know what cars are offered to our advertiser in exchange for a "diamond pin and Humber safety." Fortunately the alternative of cash is given, and that should prove more attractive than the dazzling brilliance of the diamond pin.

Motor-Cars and the Army.

IN our issue of the 18th ult., we illustrated some of the automobiles employed by the French military authorities, and now give a view of the Mors travelling telegraph office which is exhibited by the French Government at the Paris Exhibition. This is fitted with an 8-h.p. motor and has four speeds

Cliché de]

[Le Chauffeur.

ranging from 8 to 32 kilomètres an hour. There is accommodation for four persons—two seated in the front and two in a compartment at the rear. All the necessary apparatus for conducting telegraphic communication is carried on the car, which should prove a useful addition to the equipment of the French army.

Ox Wagons Cause Delay.

THAT our own military authorities will have to pay attention to the utilisation of the automobile is becoming increasingly obvious to all—save, perhaps, the War Office. A member of the Imperial Yeomanry now in South Africa has been writing on the slowness of the movement of the cavalry brigades owing to the slow transport of food and ammunition. These necessary commodities are carried in wagons, drawn by oxen

which only travel at a little more than two and a-quarter miles an hour, and they invariably stick at any spruit or steep climb which may lie in their path. In this manner a whole battalion is delayed for a considerable time, and its chances of gaining upon an active enemy are thereby made very remote. It will be fairly obvious that if the transport wagons could only move with the men at a greater, if not an equal speed, they would be the better able to bring the foe to bay, and at the same time the column would run less risk of having its supplies cut off by a convoy attack.

Motor Transport Necessary.

To overcome these difficulties and to secure greater mobility for the cavalry the ox-wagon should certainly be discarded. The provision of a number of horses fitted with pack saddles, each to carry a load of about 250 lbs. weight, is suggested, but while this would probably be an improvement on the present system the adoption of motor-vehicles would be a far greater advantage. The necessity for experiments in this direction is certainly being forced upon all observers of the war in South Africa and with the transport difficulties that will probably be experienced ere the Chinese puzzle has been solved too much attention cannot be given to the subject.

Empowering the Daimler.

IT may be remembered that during the recent Irish motor tour two Daimler cars took part which originally were of exactly the same power and geared identically. On the trial, however, Dr. Colohan's car proved itself to be considerably more powerful than Mr. Meeredy's, and repeated tests on the hills showed it was able to surmount them on a higher gear than the latter. Dr. Colohan justly attributed the improvement to the alterations which he had effected in the engine. After the trip Mr. Meeredy had his car dismantled, and then Dr. Colohan added the more important of his improvements. The result was quite remarkable. It was tried over a series of hills, the performances on which in the first instance were well known. In every case a very marked improvement was noticeable. Mr. Meeredy found he could take eminences on the high speed which previously he could only ascend on the second speed. He reckons the pace of his car up hill has been improved by fully five miles an hour. Further improvements are in contemplation by Dr. Colohan which he hopes to have ready for trial in September. At present he is reticent about details, as until his ideas are fully protected he does not wish them to be made known publicly. But in an unmistakable way he has given practical demonstration of the utility of his alterations, which, we may remark, were carried out at the works of Messrs. Hutton, Sons, and Co., Dublin.

The Motor-Car and the Stage.

IN a fashionable theatre at Berlin the motor-car has been seen on the stage. At New York it has been utilised for the performances of a couple of clever performers, and at the Alhambra it was welcomed some time ago as a change in the usual character of the performance. Now it has become the theme of the music-hall poet, and a motor-car song has been introduced by Mr. Arthur Roberts in his "H.M.S. Insuppressible." Of course "Teuf, teuf" is mentioned.

Miss Butler.

LADY automobilists are a growing numerical quantity and may yet establish records in driving motor-cars. At present the record is held by Miss Vera Butler, the daughter of the hon. treasurer of the Automobile Club, who was the first lady to drive between the English and French capitals. She is being much paragraphed just now by the Society journals, from one of which we learn she was educated at the celebrated school of the late Miss Buss, where she passed the Cambridge Local

Examinations and also obtained her certificate for music. She afterwards studied French and music for four years in Paris. Amongst her other recreations are swimming, golf, boating, cycling, and mountaineering in the High Alps. In our issue of July 28th, we gave a snapshot—taken in the grounds of Strawberry Hill House, Twickenham—of Miss Butler on her father's 6 h.p. Panhard.

The "Sphere."

IN the *Sphere* the Rev. Arundell Whatton has been telling a tale about an acquaintance who looked out for a motor-car which would not run and actually bought a second-hand machine upon the assurance of the owner that it never had. He found his pleasure in solving the problems of its obstinacy. We wish all the motor-car articles in our contemporary were as accurate in tone as that of the Rev. A. Whatton. Last week we corrected the *Sphere's* mistake with regard to the Prince of Wales. Instead of accepting that correction the Editor went on to say nothing had been heard of the car at Sandringham. Had he made inquiries at Marlborough House he would have got better information.

Motor-cars in Italy.

THE patriotic intentions of some of our Consuls abroad are highly creditable, and the following extract from the report of Consul C. C. Morgan, our British representative in Rome, will be read with interest:—The whizzing noise and the trumpeting which is now heard in the streets of Rome betoken the existence of a new industry. I find that the motor-cars in use up to the present are of Continental manufacture, and the fittings and accessories of the machines, which at this early stage are easily damaged, are imported from abroad, but not from the United Kingdom. It would be expedient for motor-car manufacturers and dealers to try to open a market here. I am confident that the superiority of the British machine would secure patronage.

Electioneering on the Motor-car.

THE ranks of political motorists are being swelled by several notable additions, and we hear that Mr. Alexander Williamson, of Blairesk Hall, Midlothian, prospective Parliamentary candidate for North Ayrshire, has started on a political tour through the constituency in a motor-car. He is accompanied by the secretaries of the various polling districts, and is visiting all the out-lying localities. Out-door meetings have also been held in several of the places in the itinerary. Mr. Tweedy Smith, the victim of the attack on a motorist reported in our columns a fortnight ago, is also a Parliamentary candidate, and the motor-car may be expected to figure prominently in his constituency—South Hants—during the contest.

The Darlington Case.

AT the Darlington police-court a case has been heard in which the motorist won on one side, and lost on the other. Those who read the report in our columns last week will wonder why Mr. Wilson Hall should have been fined for riding at an excessive speed when no evidence was forthcoming to disprove his statement that he was travelling at not more than five miles an hour. Evidently the Darlington bench requires a little practical education as to the capacity of the automobile to be stopped at the desire of the driver and also as to what is excessive speed, and what is not.

Dangerous (?) Speed at Bournemouth.

BOURNEMOUTH has been often heard of in connection with motor-car matters, and the services that have been instituted have been of great public convenience. Now some of the motor-car drivers have been summoned for driving their cars at such speed as, in the opinion of the magistrates, constitutes a public danger. The offence took place in a busy thoroughfare, and the

speed was ascertained by a policeman stationed at a given point. When the car passed, the policeman signalled to a comrade farther down the road, who at once started his stop-watch. The pace was about ten miles an hour, which the magistrates considered dangerous. They fined each defendant a small amount and costs. Seeing that the evidence proved conclusively that the vehicles could be stopped in a shorter distance than would be possible in the case of a horse-drawn vehicle, the justice of such a finding is not very clear.

Proposed Motor-Car Service in Ireland.

SEVERAL inhabitants of Enniskillen have expressed their wish and willingness to run a motor service to and from Bundoran in the summer months, and to and from the markets in the winter time, and if such a service could be instituted the cars would be largely availed of by the people of Enniskillen and district, and by tourists generally. Tourists are going to Ireland in vastly increasing numbers year by year, and they would not be slow in taking advantage of a speedy run to Bundoran along the beautiful route which skirts Lough Erne. Enniskillen folk who patronise Bundoran are sadly handicapped in that the last train back from that favourite watering-place is at 5.10 p.m. It could be so arranged to leave Bundoran by motor-car at any time up to 9 p.m., by which hour people would have enjoyed to the full the benefits of the sea. The route, which would be traversed on both sides of the lake, is very beautiful, the ever-varying scenery and panoramic views of the lake and its densely-wooded islands equalling any other scenery in Erin's Isle. We hear that several local gentlemen have conferred on the subject of a motor-car service, and it only needs the fillip of some well-organised trip to lead to the formation of such services in several places in Ireland.

The Scottish Club's Run.

SUPPLEMENTARY of the photos already published in connection with the meet of the Scottish Automobile Club, we have pleasure in giving the accompanying illustration from a photograph by Lord Kingsburgh. Included in the group is the motor-car which was used by the Forth Volunteer Infantry

Brigade in their camp at Lochcote, Linlithgowshire, and which rendered good service in carrying the mails. Lord Kingsburgh went out on the vehicle to Linlithgow to meet those taking part in the club's run, and the snapshot was taken on the road.

The Light Delivery Van Competition.

THE conditions relating to the light delivery van or *poils légers* competition, which is to be held in Paris from the 17th to the 22nd September, have just been issued. The trial is of an international character, and is open to all motor-vehicles capable of carrying a load of not less than 100 kilo-

grammes. Entries will be received at the Automobile Club de France, in Paris, until the 15th September.

A New Decauville Voiturette.

CALLING in at the Motor-Car Company's dépôt in Shaftesbury Avenue, W.C., the other day, we had an opportunity of inspecting the latest type of Decauville voiturette, which in many respects is a great advance on the vehicle with which most of our readers have been familiar for some time. In the first place, the motor, instead of being air-cooled, is now provided with a water-jacket, the circulation being maintained by a small pump driven off the fly-wheel. The engine is of the two-cylinder vertical type and develops 5 h.p.; the ignition is electrical, while a Longuemare carburettor is now being used. The water-tank is located under the small seat in front, a water-cooling coil being also provided. Other improvements in the new car are to be found in the fact that the motor and transmission gear are now enclosed by a detachable cover, and in the suspension of the body. The motor and transmission gear are supported on a tubular frame, and are entirely independent of the body, the latter being attached by springs to the frame both fore and aft. Painted in yellow and blue the new vehicle has quite an attractive appearance, and with its 5 h.p. engine it is claimed to be capable of conveying the three passengers for which it is designed at a good speed, both on ordinary roads and up hills.

A Note from Brighton.

BRIGHTON people have had a chance of seeing the motor 'bus lately running in London, and the vehicles of the Brighton Motor Co. going to Patcham and places round about have been well patronised of late. Last week Mr. Rudyard Kipling went for several drives from his house at Rottingdean on his motor-car. It took the steep ascents on the way to Brighton with apparent ease, while the four-horse 'buses went their journey with evident difficulty. Popular among excursionists, patronised by well-to-do holiday makers, and well recognised during the last few years by motorists, the wonder is that automobiles are not more familiar objects in the streets of Brighton than is actually the case. Only a few stray motor-vehicles can be seen, save along the Front, and yet there is scarcely a place on the south coast where the provision of a motor-car service would relieve horses of the strain and hardship involved in the journeying up and down the steep gradients between the station and the Front. These are really irksome beyond the customary strain of steep streets, and the numerous short inclines are very trying. Certainly manufacturers might do worse than endeavour to foster a popular motor-car service to and from the station at Brighton.

Motor-Car Services.

THE provision of motor-car services not only continues to increase, but they are being organised on such thoroughly business lines that their permanence is safely assured. Not only have they regular hours of starting and appointed termini, but time-tables are being published in connection with the services. We chronicle the fact in the hope that it will afford a useful suggestion to conductors of such services who have not yet published such guides.

More Motor Etymology.

So many attempts have been made to provide substitutes for the words automobile and motor-car without result that one would think that by this time the futility of the same would have been recognised. Although the question has not been heard of so much of late in this country, yet in America new words are continually being coined. Thus a New York etymologist writes to the *Automobile Review*:—"I beg to submit a well-considered protest against the open and painful incongruity of the term automobile. It is etymologically untenable and ought to be abandoned. It is a compound of two words

derived from two languages, Greek and Latin, that should never have been joined in unnatural and unscientific union. Give us words from one language. For example, the Greek. No more beautiful and expressive word could be imagined, I think, than tachy-drome, or swift running; purely Greek, not an illogical and awkward composite, but a true and logical compound. This word might as easily and swiftly gain acceptance as ever did the word telegram, as far as I can see. Calidrome would do very well also. Any honest, appropriate, euphonic word—not a hybrid, a jargon or jumble from two languages, like automobile—is the new term wanted. Tachy-drome is therefore recommended, or calidrome (fair running), but away with automobile for ever." Our contemporary adds that, "The word 'automobile' has become so firmly entrenched in the public mind to denote a mechanically propelled vehicle, that it would be probably easier to make water run up-hill than attempt to eradicate its use at this date." We in this country have preferred the word motor-car; and although other terms have been suggested, none of them seem likely to supplant it.

An American Contest.

At the automobile exhibition and race meeting to be held at Chicago from September 18th to 22nd there will be some interesting tests, in which the following ratios of points will be established as winning values:—

	Points.
Speed (to be determined on a 5-mile run) ...	20
Elegance of carriage design and practicability ...	20
Best arrangement of brake and control of speed ...	20
Best climbing of grades ...	20
Best and surest safety devices for operating vehicles on either grades or level ...	10
Best, simplest, and most easily accessible mechanical construction ...	10

There will be a hill-climbing contest, also a contest on an incline and decline grade, and a heavy draft contest, open for all heavy draft motor-trucks built for commercial hauling. In this contest the following ratios of points will be established as winning values:—

	Points.
Construction ...	20
Power ...	20
Carrying capacity ...	20
Design ...	20
Control ...	20

After decisions have been rendered on tests covered by above rulings, the prize-winners of each class will be allowed open competition on:—

	Points.
Carriage design for general practical utility ...	30
Easiest manipulation ...	30
Safety and emergency devices ...	20
Cost of power per ton mile ...	20
(Per ton mile to include complete weight of vehicle and passengers as well as any additional load that may be carried.)	

These points will be of interest to those who have anything to do with motor-car trials in this country as showing the relative importance attached to various points of a machine in the United States.

Useful Criticism.

ONE of the contributory factors to the success of the automobile industry has been the readiness with which designers, makers, salesmen, and purchasers have placed information at the disposal of each other. Details of construction have been criticised in the automobile press, and there seems to be a common desire on the part of all earnest workers in the industry to aid in the production of the most serviceable and most efficient vehicle, and to arrive at truths by an interchange of thought. It is this desire which is so rapidly elevating the industry.

THE AUTOMOBILE FETE AT VINCENNES.

—8—

(From Our Own Correspondent.)

WHEN I decided to honour Vincennes with my presence, it was not with any idea to enjoy myself, for the exhibition is not a very joyous place. No, it was because I desired, in the goodness of my heart, to give the unfortunate annex a chance by visiting it personally, and I selected for the occasion of my expedition, Thursday, August 23, as upon that date an automobile fête was announced to take place, and I had no desire to appropriate to myself all the honour of attracting the public. So then, at about one o'clock in the afternoon of that particular Thursday, I presented myself, equipped with a Kodak and a sweet smile, at the Palais Royal station of the new Metropolitan Railway, in front of which a long queue of would-be travellers had already formed. My surreptitious efforts to find a forward place being but unsympathetically received, I was constrained to fall in at the end of the queue and await my turn to descend into the bowels of the earth. It would indeed have proved a wearisome affair but for the entertainment generously offered to us free of charge by a fiery Frenchman, who, understanding German, resented the deprecatory nature of a criticism on his *patrie* and everything in it, exchanged between a couple of Germans in their native tongue. We all enjoyed it immensely excepting perhaps the man who nearly had his eye poked out in the discussion, but then he had no sense of humour. By a quarter to two I had approached sufficiently near to the entrance to hear the trains departing, which encouraged me to persevere, and when ten minutes later I actually arrived next to the policemen guarding the sacred portals I could have embraced them—the policemen. It was at that moment I discovered that the crowd in which I was embedded was waiting to go to the Champ de Mars, and that I could have proceeded to Vincennes three quarters of an hour previously. In a moment my smiling amiability was changed to rage, and I plunged furiously down the steps. The fares for any distance are respectively 25c. and 15c., and filled with a spirit of reckless extravagance, I determined to squander the larger sum, and take a first-class ticket. No sooner said than done, and a couple of minutes later I found myself in the train, where my ill-humour was quickly dispersed by the happy *rencontre* of Jules Dubois, bravo Jules Dubois, as Mrs. Kennard calls him, when writing of the Thousand Mile Trial. With such a jovial companion by my side the run to the Cours des Vincennes passed quickly, and the wait for the electric tramcar, usually so weary, was hardly noticed. Once aboard the car we followed the fortifications, passed the Portes St. Mandé and Picpus, and finally turning through the Porte de Neuilly, were put out at the Exhibition gates. It is really delightful at Vincennes, for nobody seems to know anything as to localities, and one may wander about in the exhibition for an hour or two without catching sight of a vestige of the show. But on Thursday there were actually some people there, so we just followed the stream and quickly reached the road running round the Lac Daumesnil, and which, roped off, served as a track for the races. This track measures exactly 2,264 mètres, and carries a broad white line down the centre to aid the *chauffeurs*. Matters commenced at half-past two with a procession of florally-decorated cars, led by the famous steam-carriage known as "La Mancelle," built by M. Amedée Bollée père, and winner of a silver medal in the exhibition of 1878. This *défilé* ended, and, truth to tell, it was not a very extensive affair, a thread-the-needle race for motor-cyclists took place, which Fossier succeeded in gaining, followed home by Laborde, Denesle, and Le Blon. Then we were treated to a real sensation—a motor-cycle race, once round the lake for the heats and two laps for the final. The first heat was won by Béconnais in 2min. 1sec., Fossier being second. The second heat was secured by Rigal in 2min. 11sec., Marcellin obtaining second place. In the final Béconnais got well away and completed the first lap in 1min. 52½sec.; Rigal lying second and Fossier third with Marcellin well in the rear.

Béconnais' second lap was made in 1min. 44½sec., which represents a speed of eighty kilomètres per hour, and the aspect of man and machine travelling at that speed was truly terrifying, for the cycle literally leapt from the ground like some new breed of kangaroo. Fossier finished second, and Marcellin third, Rigal breaking down *en route*. Then came a backward race for the voituresses over a distance of 500 mètres. The competitors were despatched in couples, and the results were:—1, Marcellin beat Wrad; 2, Ricard beat Schmidt; 3, Oury, a bye; 4, Marcellin beat Ricard (disqualified); 5, Oury beat Marcellin.

The completion of this race brought us to the event of the afternoon, the Omnium Handicap. And in what did this consist? Well, we had the bicyclists, the motor-tricyclists, the motor-bicyclists, the voituressists, the cripples, the roller-skaters, the bath-chairmen, the runners, and the donkeys competing, first separately and finally together, over a distance of 250 mètres. Every phase of this event was brimful of interest, but the series in which the public took the greatest interest were undoubtedly those reserved for the cripples, seated in those diminutive vehicles with which we are all familiar, and the donkeys. In the former class the entry of Hasslinger had deterred all other competitors from putting in an appearance, and there ere the hero of the voyage from Vienna to Paris in forty days was accorded a walk-over, which he performed at a

BÉCONNAIS—THE SPEEDY MOTOR-CYCLIST.

speed equal to 16 kilomètres per hour. But the donkey racers were legion, and the qualities displayed by the majority of them truly superb. How they coaxed and cajoled their fiery steeds, how they spurred them to still greater efforts, how they by turns whispered soothing words of comfort in their silky ears or shouted cries of battle above their heads, will live long in the memory of the spectators. I am not an expert on donkey mechanism, but it seemed to me that all the beasts were under-gear and their steering-gear defective. The majority were belt-driven, and when the belt was applied suddenly the effect was occasionally disastrous to the driver. The power generally appeared to be ample, but it was not always well applied, and the conductor appeared to have but little control over the forward and reverse gear which seemed to operate quite on its own account. Then, too, the carburation was, not up to the mark in every instance. On the question of brakes, however, I have nothing but praise, for frequently they acted with startling efficiency, and when once applied only the persuasive application of a carrot could bring about their withdrawal. But the sport is a grand one, and for the efficient exercise of every muscle in one's body it cannot be too strongly recommended. The final of the handicap went, as it should do, to the noble steed, but only after a desperate struggle with the bicyclist and the runner. The official placings were: 1, Thuan (donkey), 165 mètres; 2, Mathieu (cyclist), scratch; 3, Trante (runner), 85 mètres; 4, Guerry (roller skater), 140 mètres; 5, Hasslinger (cripple), 160 mètres; 6, Lesaint (motor-bicycle), 62 mètres 50; 7, Gama (bath chair), 120 mètres; 8, Schmidt (voituress), 80 mètres; 9, Laborde (motor-cycle), scratch.

It may be of interest to know the speeds per hour in kilomètres achieved by the various competitors. These were:—

Donkey, 15; cyclist, 45; voiturette, 30; cripple, 16; motor-cycle, 45; motor-bicycle, 33; roller skates, 18; bath chair, 21; runner, 27.

No sooner had this event been decided than Dubois and I made the best of our way to the station, a timely lift in Schmidt's little car enabling us to reach our destination before the crowd

CORRESPONDENCE.

150,000 MILES.

[TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Mr. J. E. Hutton evidently wishes to be very smart, but many of your readers will no doubt consider it bad taste on his part to publicly accuse a total stranger of deliberate perjury on the strength of an extract from an obviously incorrect report in a newspaper. The statements given in your previous issue were not as related by me. I have owned a motor six weeks and have not been much over 1,500 miles. I ask you to be good enough to insert this in your next issue, though I am loth to take up any of your space.

Foxlea, Epsom,
August 25th, 1900.

Yours truly,
G. T. LANGRIDGE.

CHARGING ACCUMULATORS.

TO THE EDITOR OF THE *Motor-Car Journal*

SIR,—Batteries of primary cells, as described by Mr. F. S. Tidecome and Mr. W. G. Bell, are not very successful for charging

accumulators with, nor, in fact, to produce any current which has to be steady for several hours. If no other charging current is at hand so that these must be used as generators, an ammeter should be connected in the wire of the feeding current and a voltmeter should be frequently used to measure the E.M.F. of each cell. This will give warning as to when new chemicals have to be added or when the whole charge has to be renewed.

At least four cells in series are required to charge two accumulators. The total voltage should be kept near 6 volts, but need not be any higher. If the voltage falls below 4 volts, the reverse of charging will take place, therefore it is necessary to watch the measuring instruments. A more successful plan to charge up is to draw the necessary current from a plating dynamo now found in most cycle repair shops. The 6 volts usually produced by these is just sufficient to charge two accumulators. A small resistance is easily and cheaply made by winding thin copper wire round a piece of dry wood or other non-conductor, and have a clip to slide along this to adjust the resistance, and a wire from the clip to run to the terminal of the accumulators. The charging current required by a pair of motor accumulators varies from 1 to 5 amperes according to the size of accumulators; to fully charge up six to eight hours are necessary, but it is preferable to continue the charging longer than necessary. The current consumed is so small that it can hardly be expressed in currency, and cycle makers should not charge too much for this if their engine is not run for the purpose. If the charging is done through electric lamps the current consumed is considerable, but it may be done at home when the light of the lamp is utilised, in which case the expense is reduced to nil.

To keep accumulators for motor-cars in good condition the following rules should be observed: Do not test with ammeters, draw sparks, or short circuit. Test with voltmeter and recharge as soon as E.M.F. in each accumulator has dropped to 1.9 volt. Never discharge below 1.8 volt. After this the accumulator discharges very rapidly and completely exhausting the charge deforms the lead oxide. To reform a completely exhausted accumulator takes 43 hours continuous charging, and two or three repeated discharges and charges to bring the accumulator up to its capacity. Overcharging in hours does not wear the plates out, but is very beneficial; charge up as often as you have occasion, but do not charge with more amperes than what the accumulator is made for. The usual time required to charge accumulators is six to eight hours; towards the end of the charge the E.M.F. in each cell runs up to 2.5 volts, in some to 2.7 volts. When this is reached they only take half the charge. After having charged up full, allow the accumulator to cool, and then test the electrolyte with a densimeter; if too strong, that is above 1,230 spec. weight, add some distilled water or boiled rain water, and reduce the spec. weight to the normal density; water continuously evaporates, but very little acid gets lost. Keep the plate well covered with electrolyte. Again test with voltmeter only; as long as the E.M.F. is above 1.8 volt, the accumulator is not discharged. The ammeter will draw a considerable amount of current from the accumulator, and it is not difficult to test an accumulator with an ammeter for a few seconds to such an extent that it need not be used again.

Yours truly,
Coventry, August 25th, 1900. H. W. VAN RADEN.

VAST sums are being expended by the Government of Madagascar on the construction of excellent wagon roads, connecting Antananarivo with the east and west coasts at Tamatave and Majunga respectively, and also with the southern district of Betsileo.

THE first instalment of the electric omnibuses for the American Autocarette Company, of Washington, D.C., has arrived. The vehicles are to be run on the storage-battery system, and are equipped with solid rubber tires. Each vehicle has accommodation for twenty passengers. The first line to be permanently established will run the entire length of the city, on a route passing nearly all the Government buildings.

ACCORDING to *L'Automobile Belge* there are now 321 motor-cars and 108 motor-cycles in the province of Brabant. Next comes the province of Liège with 148 cars and 94 motor-cycles, Antwerp with 55 and 34, Hainaut with 42 and 39, East Flanders with 8 and 7, West Flanders with 25 and 3, the province of Namur with 14 and 9, Luxembourg with 7 and 3, and Limbourg with 4 voiturettes. This gives a total of 1,119 motor-cars and 297 motor-cycles already in use in Belgium.

A MEETING of manufacturers of petrol motor-vehicles, and of motors for automobiles, which was called for the purpose of forming an association to fight the Selden patent, owned by the Electric Vehicle Company, took place in Buffalo, N.Y., U.S.A., on the 2nd inst., with about twenty manufacturers of vehicles and motors in attendance. After a two and a-half hour discussion of the merits of the Selden patent and the necessity of an association, a committee on organisation was appointed. The committee made nominations for officers, and the nominees were all unanimously elected as follows:—President, Mr. Elmer Apperson, of the Haynes and Apperson Company, Kokomo, Ind.; Secretary, Mr. George H. Brown, of the Winton Motor Carriage Company, Cleveland, O.; Executive Committee: Mr. E. B. Gallaher, of the Keystone Motor Company, Philadelphia, Pa.; Mr. H. M. Sternberg, of the Duryea Power Company, Reading, Pa.; Mr. A. Snyder, of the Buffalo Gasoline Motor Company, Buffalo, N.Y.; and Mr. John S. Clarke, of the Autocar Company, Ardmore, Pa. It may be stated that every manufacturer present appeared to be thoroughly in earnest in his opposition to the Electric Vehicle Company's attempt to monopolise the petrol motor in America, and determined to stand by the Winton and Buffalo companies in their fight.

THE NEW LEYLAND STEAM WAGON.

A NUMBER of improvements and modifications have lately been made in the steam wagons built by the Lancashire Steam Motor Company, of Leyland, notably the adoption of coke in place of liquid fuel for the firing of the boiler, and the employment of an horizontal engine in place of the vertical. The accompanying illustration shows one of the latest productions of the company, a steam wagon capable of carrying loads up to four tons. The boiler is placed in front, as usual, and has 89 square feet of heating surface. It is fired from the driver's seat through a central shoot, and is constructed for a working pressure of 200 lb. per square inch. Water is fed to the boiler by means of a brass feed pump, placed under the engine frame. There is also a small Worthington steam pump under the driver's seat, which is used for pumping water into the boiler when the machine is standing. This pump can also be worked by hand in case it is required to fill the boiler when steam is down. Before entering the boiler the water passes through a heater which raises the temperature from say 50° to 180° Fahr. The coke bunkers are placed on either side of the boiler. The engine is hung under the centre of the frame in such a manner that the bed is, it is claimed, relieved of all the strain usually put upon it by the driving wheels. It is of the double-acting compound type of 20 h.p. It has metallic packing throughout, large

THE NEW LEYLAND STEAM WAGON.

wearing surfaces, and is fitted with link motion for reversing. The whole of the working parts run in a dust-proof oil bath. The gearing, which also runs in oil, is arranged to give two different changes of speed, one equal to five miles an hour with the engine running at 400 revolutions per minute, the other three miles per hour with the engine running at the same speed. A special cushion drive is used for transmitting the power from the compensating gear shaft to the rim of the road wheels, thus reducing the shock to the working parts when starting a heavy load. The axles are of girder section, the arms being of large diameter, while the wheels are made on the gun-carriage principle, the hubs being steel, bushed with bronze. The seat will accommodate three persons, although one man is sufficient to handle the machine. The platform is made with oak framing and teak bottom, well supported with ironwork. It is 12ft. long by 6ft. wide and rests on the main steel framing, being entirely free from the machinery. The platform can be removed after taking away the bolts that keep it in position, thus enabling other forms of body to be used. The main framework is made of channel steel. The whole of the machinery, boiler, and tanks are hung or rest on this frame, which is supported from the axles on long laminated steel springs. The steering is operated by means of worm and wheel gear, working in connection with pivoted axles on the Ackerman principle. The makers claim that the vehicle is capable of doing a journey of fifty miles in a day of twelve hours, loaded with four tons, providing that the

roads are in good condition and not a very hilly district, and that it will take this load up gradients of 1 in 7 on reasonable roads.

THE TRIALS OF THE TYRO.

WONDERFUL are the experiences of the novice in pig-sticking, duck hunting and mountaineering. Equally sensational can be the incidents associated with our own particular sport. Learning to drive a motor-car probably comes as near the heart disease limit in human doings as any one event of ordinary life. When Richard III. made his famous bid for a horse, the automobile was not. There are many sportsmen, probably, who cordially echo the cruel king's cry: "A horse!"

a horse!" anything whatever less cranky, cantankerous, crotchety, and with a more subdued enthusiasm for riding over everything but the road. It seems so easy while one watches the automobilist. The thing shoots along the road at a rattling pace, corners are turned with surprising ease, the apparatus comes gracefully to a standstill; in fact, it "gees, haws, and backs" with all the docility of a well-trained horse. When the owner takes it in hand for the first time, then it is truly "a horse of another colour," and certainly of a different—oh, how different—disposition. All the vices and irregularities of the sum total of equine perversities are as nothing compared to it.

After explaining the thing and illustrating the action of the starting lever, steering bar, reversing lever, and brake, by sundry dexterous turns of the wrist, the instructor changes places with the luckless beginner, and then the fun begins. Particularly if one is accustomed to horseback riding is the first trip on an automobile a strange and fitful experience. "This is easy," the new automobilist says to himself as, with the right hand on the steering bar, he pushes the starting lever a single notch forward. This only sends the machine at a very moderate pace. The road is straight and smooth, and everything goes easily. There is a feeling of exhilaration, and, with a thought of "I wonder who I know is looking," the new operator rashly pushes the lever forward as far it will go.

With a bound like that of a high-bred horse under the sudden sting of the whip, the machine bolts forward. The steer-

ing bar, which was so easy to handle at the slow speed, now seems to be endowed with life, instinct with some diabolical agency. It will never stand still. Instead of keeping straight ahead, the machine is continually wobbling, and woe to him who may be driving anything on that road. The perverse machine takes it all, with an absurd preference for the pavement. Then the instructor comes to the rescue and saves the venturesome amateur from an untimely death. With a change of heart amounting to a camp meeting conversion the machine, which was a moment before vicious, hard on the bit, stubborn and obstinate, lays aside all these vices and, coming back to a state of grace, darts along the road like an express train. While the new driver is drawing a breath of relief and wondering what could have possessed the machine before, it comes as a shock to hear the instructor saying: "You rather lost your head that time. Now, try it again, and keep the steering bar steady."

Holding the steering bar with a grip that almost dents the handle, the motor-car speeds on. No deviation this time; straight as an arrow the thing shoots. Down the road speeds the machine, when, all of a sudden, half a newspaper blows across the road. The new operator, with all his experience of horse-lack riding, needs no hints from the instructor as to what he should do in this emergency. Holding the starting lever firmly with his left hand—though what for, neither he nor any one else could say, as the machine is doing its best already—and the steering bar in his right, he deliberately turns his horse's—no; the automobile's—head toward the fearsome object. Almost instantly the machine becomes a bicycle, so sudden is the slew that the quick turn has caused. The instructor seizes the steering bar, and, by bringing it back to "straight ahead," averts an overturn by a hair. "Never had a horse shy like this," mutters the neophyte, as he takes the bar again.

All goes well for a time now. The machine is on third speed and acts very well. The third speed is not very slow, however, and before long the automobile arrives at a street where the tram-lines cross the road. Still thinking of the horse, and wishing to keep the thing from stumbling on the tramway, the new beginner slows up. Where, oh, where is that brake! After more or less shuffling, the foot finds it, and, with a forward pressure, releases the catch that holds it in position on the rack. Gently as possible the thing stops. The lines are crossed and no accident has happened.

The first half mile is now done without much pleasure. One's whole mind is centred on the management of the machine. The surrounding scenery is enveloped in a sort of haze. Little by little, as ground is covered and nothing untoward happens, the new operator begins to notice other things. That was a handsome house that was passed, he thinks to himself. One by one objects begin to impress themselves on the senses. Sometimes, like Toby, M.P., he fancies he sees a policeman who is out of sight before he can enter into conversation. The mist clears, and with a keen sense of pleasure and exhilaration, the next half mile is passed. Everything is going smoothly. The machine has been conquered, and the speed lever is pulled to the next notch. At a rattling pace the automobile now dashes on. Automobiles for ever. Horrors! Is that nurse going to trundle that perambulator across the street? Will she never look this way? Down brakes, quick! As the new driver painfully gathers himself together and sorts himself from the clinging gravel and mud that has stuck in artistic clusters on his clothes after he went flying over the dashboard, his criticisms of the sport of automobilism are not fit to print. If he is not cured, the automobile fever is in his blood and he will try again, each time with increasing pleasure. And the probability, nay, the veriest certainty, will be that he will feel the contagion of the sport that is now causing men to leave other pastimes to join in the exhilaration of going along the countryside without the help of the horse—a fine new invention for up-to-date persons. As a cure for bad nerves the automobile is A1.

At Leamington, on Monday, Ambrose Valentine, engineer, of Heath Terrace, was fined £1 for driving a motor-car without a front light.

THE CARCANO MOTOR-BICYCLE.

THE latest motor-bicycle to come under our notice is that which has recently been built to the designs of the Marquis Carcano and put on the market by the *Agencia Internazionali Automobilistica*, of Milan, Italy. A general view of the machine is given in Fig. 2, from which it will be seen that the motor *L* is placed in front of the main down tube of the frame and supported at *E* and *N*. The motor, of which a separate view is given in Fig. 1, is of the air-cooled type with electrical ignition. It has an external fly-wheel, a small pulley being fixed on the

FIG. 1.—GENERAL VIEW OF CARCANO MOTOR.

opposite end of the crank shaft. The engine drives the machine by means of a strap working on a light rim attached to the rear wheel. The petrol tank and carburettor *B* has a capacity of two litres. The accumulators are located at *A*, and the induction coil at *G*, *Q* being the silencer. In the details sent us by the makers the horse-power of the engine is not stated nor is the weight of the machine complete. The motor, with its carburettor, battery, etc., is stated to weigh about 30 lbs. Pedals and chain-gear, combined with a free-wheel clutch, are provided to enable the engine to be started or assisted in mounting steep gradients.

THE Western Automobile Association, an organisation for automobilists, has been formed in Chicago.

IN Mr. R. A. COBB's letter on pneumatic tires and punctures in last week's *Journal* "a great loss of resistance" should have read "a great loss of resilience."

"THE INVENTOR'S ADVISER" is the title of the fifth edition of Mr. Reginald Haddan's work on patents, which is published by Messrs. Harrison and Sons. It deals with the commercial aspect of inventions, the British law of patents, foreign patents, trade marks and designs, and has several useful appendices.

AN electrical hotel omnibus has been lately constructed by the *Gesellschaft für Verkehrsunternehmen*, of Unter den Linden, Berlin, N.W., for the Kaiser Hotel, in that city. The vehicle has accommodation for ten passengers, in addition to the driver, and can run a distance of from 25 to 30 kilometres on one charge of the accumulators, which are located under the driver's seat. A full description of the *Verkehrsunternehmen* Company's vehicles was given in the issue of the *Motor-Car Journal* of September 22nd last.

PARIS EXHIBITION NOTES.

(FROM OUR OWN CORRESPONDENT.)

(Continued from page 428.)

THE display made by the Compagnie des Automobiles et Cycles "Hurtu," of Neuilly-sur-Seine, is a large and varied one, embracing as it does cycles, voiturettes and cars. First of all there is to be seen, right in centre of the stand, a 12 h.p. four-seated car of the "tonneau," or wagonette type. A horizontal two-cylinder motor is carried upon the fore part of the frame, in a very similar position to that adopted by MM. Turgan and Foy in the construction of their cars—that is to say, the two cylinders are placed end to end with the crank chamber between them. Unlike the smaller cars of "Hurtu" construction, tube ignition is employed. Inclined wheel steering is fitted, and the speed change lever is found to the right hand of the driver, that manipulating the forward and reverse gears being placed directly in front of him. Three pedals are provided, two acting upon the friction clutch, and the third upon the governor when it is desired to accelerate the speed of the motor. The car has a solid, substantial appearance, but it cannot be styled a graceful vehicle by any manner of means. Turning from it, we find a couple of carriages of the type so long associated with the name of "Hurtu."

The one is a four-seated back-to-back dog-cart, smartly upholstered in red leather, and carrying a 6 h.p. motor, while the other is also a four-seated carriage, but fitted with a 7 h.p. engine. In both instances the motor is attached to the rear part of the frame, and by reason of the method of balancing the constructors claim that no appreciable vibration is communicated to the car. A horizontal engine, it is water-cooled, and a couple of large tanks ensure the accomplishment of long journeys without the necessity of replenishing the supply of water. The ignition is electric, and the special coil used is said to communicate a spark of great intensity. In common with many motors of Benz origin the engine is started by means of a fly-wheel, which method is not free from objections on the score of cleanliness. The driving is effected by the medium of belts. From these medium-sized cars we come to the small fry, and in the voiturette class a couple of dainty little vehicles are to be seen. The double suspension and the direct transmission employed on these cars at once attract the attention, for both are special features of their construction. The motor used is the 3 h.p. water-cooled De Dion so much in favour with all constructors of voiturettes, and a better engine than which it is difficult to imagine. When desired, however, the water-cooled Aster can be fitted to the car. Three forward and one reverse speeds are provided, all intermediary variations being obtained by means of a friction clutch. A radiator is fitted, and a tank carrying sufficient petrol for a ninety-mile run is provided. The two cars shown are each designed to carry three persons, and weigh some 275 kilogs. each. The advent of this little car is a distinct gain to the ranks of the voiturettes, and the "Hurtu" firm are already doing excellent business with it.

The productions of M. H. Lepape, of Puteaux (Seine), are always known for their originality, and the single vehicle

exhibited at Champ de Mars is no exception to the rule. A two-seated carriage, with a small bracket seat for a child: the body of this car is entirely suspended from the frame by means of four Cee springs, thus securing for its occupants the entire absence of all vibration from the running of the engine. This latter is of 5 h.p., and is unprovided with either flanges or water-jacket, the cooling being effected by the fly-wheel. The carburettor, too, is of M. Lepape's design, and, unlike the generality of these instruments, it contains no float. Three speeds and reverse are provided, all being actuated by the same wheel, which is carried on the steering-wheel pillar. The motor is placed in the front part of the frame, and the transmission of the power is effected by leather belts.

For a long time past considerable attention has been directed to the productions of the Gardner-Serpollet Company, Rue Stendhal, Paris, and this interest has of late been greatly intensified by the Shah of Persia's experiments with, and purchase of, a couple of Serpollet carriages. Personally, I have heard—indeed, continue to hear—nothing but favourable criticisms passed upon the latest types of vehicles produced by the firm, and it is evident that the new Serpollet car is a distinct advance upon any steam carriage hitherto constructed. Of the three types of vehicles exhibited, the voiturette perhaps attracts the most attention, for steam-cars of so small a size and of so dainty an appearance are

indeed a rarity. It is built to carry two persons, but a small bracket-seat, or "strapontin," placed in front of the passenger, gives accommodation for a third voyager. The motor develops 5 h.p., and is placed in the centre of the frame, the boiler being carried behind. Sufficient oil and water are carried for a sixty-mile run, and the consumption of the former is at the rate of one litre for every three miles and three quarters covered by the car. A single speed is provided, and this attains

FIG. 2.—THE CARCANO MOTOR-BICYCLE. (See opposite page.)

twenty-five miles per hour upon level ground, and enables the car to ascend grades of 20 per cent. Practically the whole of the mechanism is mounted on a single plate attached to the frame by four bolts, which renders remarkably easy any inspection or repairs which may be found necessary. The boiler contains eighty metres of tubes. The steering is irreversible, and is actuated through the medium of a wheel. Upon the steering pillar are found a couple of small levers, the one acting upon the pumps, and varying the quantity of water and simultaneously the quantity of oil injected, and the other actuating the cam shaft and permitting, following its position, forward and reverse motions and stop. The two pedals appearing through the foot-boards operate respectively a brake of the Lemoine type and the admission of vapour from the boiler into the motor. The carriage work is by Kellner, and presents a very smart appearance. The two other vehicles are both provided with 8 h.p. motors, and carry some 120 metres of boiler tubes. The one car is a brougham affording accommodation for two persons in the interior and driver and footman outside. The third carriage is a four-seated phaeton. A few remarks relative to the organs of the Serpollet car may be of interest, and I would commence first of all with a brief description of the motor, which has been the object of the firm's principal efforts. It consists of four cylinders grouped *vis-à-vis* at an angle of 45 degrees, and each of these cylinders is absolutely like that of a petrol-motor.

By this means the ever-troublesome stuffing-boxes have been entirely suppressed, and with them the loss of power, which exists in the best constructed steam engines, and which on small motors assumes sensible proportions. The connecting rods are attached direct to the pistons, of which the steam tightness is secured by a series of three piston rings. The usual slide valves and fittings are also suppressed, the distribution being secured by means of valves actioned by a succession of cams keyed on to the commanding shaft. On starting the engine the shaft is forced to the end of its course, and it always happens that one at least, and often two valves are found in the position of admission; the third, or two others, as the case may be, being in the position of escapement. The reversing of the engine is obtained by an inverse admission secured by changing the position of the cams, instead of reversing the slide valve as usually done on steam motors. One of the features of the engine is the means employed for the variation of the force. This is achieved by the lateral displacement of the cam shaft and the corresponding variation in the length of time during which the valves are open, with a like increase or diminution in the amount of steam admitted to the cylinders. Turning to the generator, we find it to be of the instantaneous vaporisation type without any appreciable capacity. The circulation is forced, and when in running order it contains no reserve of steam or of water. At each instant, and corresponding to the requirements of the motor, there is admitted to the generator a certain quantity of water, which is converted instantly into steam. This is effected by the heat supplied from a series of Bunsen-like burners, employing ordinary lamp oil as fuel, and which can be set burning within six minutes from standing cold. In common with all builders of steam-cars, M. Serpollet claims for his generator that fouling is an impossibility, and puts forward the following reasons in support of his contention: 1. The considerable speed of the circulation prevents the formation of deposits. 2. The variation of the feed displaces continually the point of vaporisation where the deposits have a tendency to form. 3. The frequent cleansings, whether those automatically provoked by the play of the safety valve or those caused by the wide opening of this valve each time that the car is finished with, produce a violent return of steam and air which sweeps the interior surface of the tubes. 4. The condensation of the exhaust steam partially cleanses the feed water, and finally the drops of oil forced into the reservoir, and which occasionally are drawn into the tubes, prevent the adhesion of deposits. Connecting the generator and the motor there is a special feed apparatus, which varies the production of steam as may be desired. To effect this, not only is the quantity of water admitted to the boiler exactly regulated, but also the oil burned by the lamps, so that the diminution of heat is always followed by a corresponding diminution in the water supply. The connection of the pumps feeding respectively the burners and the boiler brings about this effect, which results in great economy of both oil and water. The arrangement of all controlling levers leaves nothing to be desired, and I am confident that ere many months will have passed one will see many Serpollet cars on the streets of Paris.

A smart little car, rather resembling a miniature Amédée Bollée in appearance, is exhibited by MM. Gillet, Forest & Co., Saint Cloud (Seine). Weighing 400 kilogrammes, this little vehicle is designed to carry three persons. The motor is of the single cylinder type and develops 5 h.p. No pump is used for the water circulation, and the transmission is direct. Electric or tube ignition is fitted as may be desired by the client. Three speeds and reverse are provided.

A curious little vehicle is exhibited by MM. Brouhot & Co., of Vierzon (Cher), and consists of a coupe built to carry a couple of persons inside, and a third on a dickey behind. The motor is of the two-cylinder horizontal type, and is placed right beneath the body of the car, where it probably finds itself as inaccessible as any motor could desire. The driving is done from the interior of the vehicle, and by reason of the evident inability of the conductor to see anything a little to the rear of him, this should prove an interesting operation in crowded streets. Other cars exist where the driving is effected from the

interior, so the Brouhot vehicle is not alone in this respect, but in no case can the management and the steering be really properly performed.

THE BAUDIER VOITURETTE.

REFERENCE has already been made in these columns to the neat voiturette recently put on the market by M. Georges Baudier, of Rue Garnier, Neuilly-sur-Seine, France. We are now able to publish an illustration of the little car, which takes the form of a "Spider"—that is to say, it has two seats in front and a light seat behind. The frame is built up of steel tubes and carries in front a $3\frac{1}{2}$ h.p. water-cooled De Dion or 5 h.p. Aster motor as desired, the water circulation being secured by means of a small pump. A radiator is fitted underneath the fore part of the car. The De Dion carburettor is used, and wheel-steering is usually fitted. The transmission,

which is on the lines of that adopted in the Renault cars, is direct by means of a friction clutch, and a special gear, the pinions of which are always engaged. In the car illustrated three speeds forward—ranging up to 40 kilometres an hour—and a reverse motion are available, the speed change gear being controlled by the lever at the right of the driver. Provision is made for starting the engine from the driver's seat, and ample brake power is provided. The wheels are of the cycle type, shod with pneumatic tyres. The petrol tank has a capacity of 15 litres and that for water 14 litres. The body can be readily detached from the frame, it being secured thereto by four bolts. A contact button placed on the steering gear enables the electric current to be cut off when desired. M. Baudier also constructs a lighter and cheaper car fitted with but two speeds.

AMONG the latest Berkshire patrons of the motor-car are Mr. Lloyd Baxendale, of Greenham Lodge, Newbury, and his brother, Mr. Frank Baxendale, who have got two wagonettes for use during their stay in the country.

THE Board of Boulevard Commissioners of Jersey City, U.S.A., has adopted an extensive series of rules governing the use of vehicles on the boulevard in that city. The speed limit is twelve miles an hour, and bells and lamps must be carried by all "bicycles, tricycles, auto and loco-motiles and similar vehicles."

IN Dowell's Rooms, Edinburgh, last week the works of the Madelvic Motor Carriage Company, now in liquidation, were offered for sale at the upset price of £7,000. The works, which are situated on two pieces of ground alongside the Granton branch of the Caledonian Railway at Granton, were purchased by Messrs. J. S. Galbraith and McCall, Glasgow, for a client.

THE CLEMENT-PANHARD VOITURETTE.

THE other day we had an opportunity of inspecting at Messrs. Friswell's dépôt on Holborn Viaduct, several examples of the Clement-Panhard voiturette. The little car, of which a general view is given in Fig. 1, is being made in France by Messrs. Clement, of Levallois-Perret to the designs of Commandant Krebs, of the Panhard-Levassor Company. It is propelled by means of a single-cylinder motor of $3\frac{1}{2}$ h.p. (Fig. 3) having an air-cooled cylinder, and water-jacketed combustion chamber, the water circulation being maintained without the use of a

FIG. 1. THE CLEMENT-PANHARD VOITURETTE.

pump. The ignition is by means of an incandescent tube or electrical as desired, whilst the carburettor is of the Phénix type. As will be seen from Fig. 2, the motor is located in the rear of the frame at a slight angle to the ground in such a way that all the valves, etc., are readily accessible at the back of the car. The engine is provided with a centrifugal governor, which is so arranged, when the speed becomes too great, as to close the admission valve. Three speeds forward and a reverse motion are available; the engine drives through a friction clutch, a short shaft in line with the motor-shaft. On the shaft are three pinions, which, while always rotating therewith, can be moved along it laterally so that any one of them can be brought into mesh with corresponding pinions on the differential shaft; from the latter the power is transmitted to the rear axle by the usual sprocket wheels and chains, means being provided for taking up any slack or wear in the

FIG. 2. SECTIONAL ELEVATION.

driving chains. Steering is controlled by an inclined wheel which actuates the two front wheels through a plain axle which turns on a central hub, these wheels being placed so far forward as to make the wheel-base long, thus ensuring steadiness in running at high speeds. Two brakes are provided, one operated by a foot

pedal and one by a hand-lever. The road wheels are of wood and are shod with pneumatic tires. The petrol and water storage tanks have a capacity sufficient for a continuous run of five hours, the maximum speed of the car being given as eighteen and a half miles per hour.

MOTOR-CAR TRIP.

IN THE WEST HIGHLANDS.

ALTHOUGH the West Highland "season" has reached its height, there are several weeks yet to be enjoyed on the west coast of the northern part of the kingdom. Just now the hotels at Oban and Fort William are pretty full, and many parties evidently intend touring on some of the roads in that district. As it is not improbable that some motorists would like to enjoy the beauties of that part of Scotland, the following hints are not inopportune.

Certainly the most appreciated approach to Oban from the south is by Ardrishaig. Reaching this early in the afternoon, the motorist would have plenty of time for a lazy ride—taking it easy to see the delightful scenery—over the good road through the pass of Melfort, along Loch Fochan, and after a stiff ascent enter Oban by means of a long descent.

FIG. 3. VIEW OF CLEMENT-PANHARD MOTOR.

From Oban the road eastward along the shore of Loch Etive is in very good condition until the Pass of Brander is reached. There it becomes softer and is largely grass-grown, owing to the decline of coach traffic since the opening of the railway, but as Loch Awe is neared the surface improves considerably. Then from Dalmally to Tyndrum it is excessively trying. Fortunately the descent through Crianlarich is excellent. The road northwards from Oban is always rather troublesome, and is now still further disturbed in places by extra traffic incidental to a new railway extension to Ballachulish. The views, however, are charming, perhaps the best being that of the bay above Appin, with the ruined Castle Stalker perched on a tiny islet, though the view westwards across Loch Linnhe to the mountains of Morven from Ballachulish is also very fine.

The passage of Glencoe may be found rather difficult, and crossing over to the dreary moor of Rannoch somewhat lonely. The head of the glen is twelve miles from Ballachulish, and not half of this distance can be called bad surface. Passing the slate quarries and village of Ballachulish and the Macdonald Stone, the scene of the massacre, the car should be left by the edge of a lonely tarn and the passengers climb up some 800ft. to get the best view of the three grim sister guardians of the glen, noting on the way the deep and long slot called Ossian's Cave. In this way Glencoe will be seen in the easiest fashion. From Ballachulish Ferry to Fort William is hardly in such good condition as usual. From Fort William a fine, almost level, run eastwards along the shore of salt Loch Eil leads to Glenfinnan and Prince Charlie's monument, and afterwards the road is exceedingly beautiful though decidedly hilly. The railway extension does not tend to improve the condition of the road, and the same fate may overtake this one as has already played havoc with the Pass of Brander.

The Falls of Foyers are still worth visiting on occasions of flood, but only then, and as these are not the occasions usually chosen by automobilists for a ride—though in a terrible storm a correspondent of the *Manchester Guardian* lately noticed four macintoshed and luggage-laden cyclists in Glen Ogle—the sight may perhaps be omitted from the motorist's itinerary. The name is said to denote a "cloud of spray," which used to be visible rising from the dense wood, but now there is only a cloud of smoke rising from the aluminium works, which have harnessed the water power for their advantage.

THE COTE VOITURETTE.

WE are herewith enabled to give an illustration of the attractive little car lately put on the market by La Société des Automobiles et Moteurs Cote, of St. Dizier (Haute Marne), France. The motive power is supplied by a two-cylinder horizontal motor developing 3 e.h.p. Electrical ignition is adopted, as also a water circulation to the cylinders. The engine runs at a speed of 600 revolutions per minute, and is well balanced, there being one explosion or impulse at each revolution of the crank shaft. As regards the transmission mechanism no chains or belts are employed, the power of the engine being conveyed direct to the rear axle by spur wheels. Three speeds forward—8, 18, and 32 kilometres per hour—and a reverse motion are available. The change speed gear consists of a train of cogwheels and clutches, a feature being that the wheels are always in mesh with the corresponding pinions in the box on the rear axle. Provision is made whereby the engine can be started from the driver's seat. Ample provision is made in the way of brakes and lubricators, while all the control gear is mounted on the steering column. The wheels are of the cycle type shod with pneumatic tires. The Cote Company are also building a three-seated car. This is constructed on similar lines to the vehicle illustrated herewith as regards the general arrangement of the transmission gear, but is fitted with an engine developing 4.8 h.p.

THE COTE VOITURETTE.

THE Remington Automobile and Motor Company, recently incorporated, is establishing works at Ilion, New York, U.S.A. The company will manufacture petrol, steam and electric motor vehicles and also small launches.

THE Waltham Manufacturing Company, of Waltham, Mass., U.S.A., who have been making motor-tricycles and quadricycles for some time, have just introduced a voiturette. The car, which has been named the Orient Victoriette, is fitted with a $3\frac{1}{2}$ h.p. water-cooling Aster or De Dion motor. Although it is only intended for two persons, the front is formed into an auxiliary seat which can be used in an emergency, where it is desired to carry three or four people over suitable roads.

THE DEVELOPMENT OF THE MOTOR-CAR.*

(Concluded from page 433.)

THE present year may be said to be a crucial one in the development of the automobile into permanent lines of design of motors, running gear and bodies best adapted to each of the kinds of motive power. When you first sit in a motor-carriage and feel yourself being carried over the ground with no horses in front of you, it produces a pleasurable sensation. As you become more accustomed to it, the feeling grows to one of delight, and lastly you are completely "carried away" with it. You experience only half the joyous possibilities of a motor-carriage when riding as a passenger. The other half, we have learned, is the driving. When you have the steering-lever in your hand and can speed ahead at your own pleasure by simply pressing a button or lever; when you wish to lessen or increase the speed, or to make a quick run with a neighbour, then it is truly a new and delightful sensation. The vehicle of this type is so easily and safely controlled that one soon

acquires the feeling of perfect confidence in himself and the motor. You can stop so suddenly, turn so abruptly, or go backwards almost as quick as thought. Happy should be the owner of an automobile. While the over-enthusiastic journals and newspapers are harping on the passing of the horse, it may justly be claimed that an incompetent driver of horses may cause as much damage as one on an automobile, but as men have been driving horses for several thousand years it is fair to presume that the green hands in the business are fewer than those in the art of steering a motor-carriage. If we are about to

change to a new mode of locomotion, this is a good time to begin demanding a certain amount of skill and knowledge on the part of the man at the lever. The fee for examination in cities should be nominal, and the board of examiners should be made up of engineers and experts in such machinery. There is no reason why the licence feature should be any more of a hardship than it is for drivers of public vehicles. It is certainly desirable for the general public that none but competent men be allowed to manipulate the new vehicles, especially for the next few years, while the horse is becoming reconciled to the new order of things.

In providing for the limit of speed allowed to automobiles there is no reason why the regulations should be any more severe than those now in use to prevent fast driving with horses. Reckless speed—with horses, bicycles and automobiles alike—is chiefly a matter of place and time. A speed that is perfectly safe on an empty street might deserve arrest of the driver in a crowded park. An arbitrary limit of some kind must be set, but

*Abstract from introduction to Mr. Gardner D. Hiscox's work on "Horseless Vehicles, Automobiles, and Motor-Cycles." (London: Sampson Low, Marston and Co.)

its enforcement, as in the case of bicycles, will have to be left largely to the discretion of police officers. The licensing of the drivers will be a far more effective check upon reckless speed, for one or two offences of this sort can be made the occasion of taking away a driver's licence. The ordinance new in force in Paris should be a useful model for the proposed measure in the cities of the United States.

The pleasure carriage is essentially an article of luxury, and it has required hundreds of years of use and the talents of the most skilled to bring it to its present perfect condition, and riders will demand of automobiles the same freedom from noise and the same ease of motion that they get with the horse-drawn vehicle. Cabs and other public conveyances, as well as vehicles for freight purposes, must be provided with positive, reliable power, one that is quick to respond to the calls made upon it, and one that will give the best results with the lightest possible weight; one, too, that is simple, effective and economical. Capital stands ready for *bona fide* investment in stages and trucks as well as in pleasure vehicles, just so soon as motor builders can guarantee their motors to do what is required of them.

point with the purchaser. If for recreation, freedom from the thought of complicated parts and movements and the vexation of finding defects while on the road are most necessary conditions in the design of the horseless carriage. Let the lovers of racing sport only hold the reins of the fast automobile and enjoy its dangers.

There is much improvement yet to be made in all the modes of generating and applying power to the motor machinery as well, also to the reduction of weight and parts without losing the required strength for the proper work of the vehicle.

In the design and construction of the automobile one thing has been apparently lost sight of that will be greatly missed, and that is storage space. Under the seat and back of same in the buggy of the doctor or the country parson there was room for a hamper of provisions for the picnic party, a grip of the traveller or some supplies for the needy. In the light runabout of the contractor or jobber the same space gave him accommodation for tools or samples, and in the carriage in general such space, out of the way of the occupant and always at hand, has been looked upon as a necessity. This space in the automobile is occupied by the

MR. M. CAPPELLETTI ON HIS "MAYFAIR" VOITURETTE.

Already the tendency at this stage in the progress of manufacture of automobiles of all kinds of motive power is to meet the desire of owners and operators of these vehicles for great power and fast speed. This should be guarded against as tending to encourage road racing, which is not desirable in a pleasure carriage and should be confined to models for racing on suitable tracks or speedways. No one thinks of driving a horse up a hill at full trot; a slow walk seems to satisfy most driving tourists. Then why should a motor-vehicle be over-loaded with machinery and itself made heavier to accomplish excessive speed either on the road or in hill climbing. This idea is especially pointed for family comfort on the road and for touring. Where is the pleasure of rushing through the country at break-neck speed with eyes riveted upon your machine gear and losing the scenic beauty of travel?

This is most applicable to the man of business who owns an automobile and wishes to derive relief from business cares and vexations by a pleasurable drive in a vehicle that gives confidence in its simplicity of running gear and ease of management. The cost is also in favour of simplicity of construction as well as a

driving mechanism, and when on a touring trip the baggage is necessarily piled upon the carriage in a manner that suggests a moving day. Space for grip or baggage is one of the things in order of improvement in automobile construction.

There is nothing of importance that we are waiting for to add to the automobile. No startling inventions are called for, and none probably are coming to solve the motor problem. All the mechanical essentials have been devised seemingly complete and ready at our hand. It is the combination and adaptation of well-known details that is needed to perfect the automobile mechanism, rather than pure invention. Many of the detailed parts have been brought into practical use within the past few years and are held under patents to the detriment of progress in automobile construction on the best lines of mechanical design.

The bicycle has throughout its marvelous development been preparing the way for a vastly greater vehicle than itself. The tubing, the wheels and tires, the ball bearings, the sprocket and chain, the steel for every part, and the numerous products of automatic machinery have contributed to the perfect action of this elegant and speedy adjunct to the human motor. Time and trial

with the modern means of manufacture will evidently bring weight and power to their respective limits in the later vehicle for strength and speed. The enthusiastic designer of automobiles may be led to ignore or forget precisely what is really needed, and purchasers may not realise exactly what they want. We want, perhaps, least of all for a pleasure carriage, a racing machine. Speed records will never establish permanently any any type of vehicle or motor.

The typical horse that has been such a valued helpmate of man is not the racehorse. Neither is the making of long runs over rough roads the thing alone to be kept in sight in designing the vehicle. Thousands of horses, especially around our cities, never go more than ten miles from home, and never see a piece of rough road. Let the roads, to some extent at least, be smooth for the vehicle, and let not all the concessions be made by it. Let us first try to produce serviceable, ever-ready and easily-managed automobile vehicles that will run upon good roads without costing too much, either at first or for repairs, and let us use them and find pleasure and comfort and convenience in them upon our good roads and for comparatively short runs, and when this service is fully established improvements will follow rapidly, until we will be able to go everywhere and do everything with them. The roads will be smoothing themselves to entice the automobile further and further from home, until it becomes ubiquitous.

We may expect progress in the development of the automobile in several directions at once. We may build the highest types of pleasure vehicles first, for wealth and leisure to enjoy, the racer for the sporting community, and from that we may meet the larger service of the more numerous classes, with the motor-bicycle and tricycle; while, on the other hand, we may speed up and lighten the traction engine, transforming it successively into the auto-truck and the delivery wagon, until the developing types shall meet and fully cover all requirements.

DR. MEECH, the newly-appointed medical officer of Halifax, is a new recruit to automobilism, and is driving a doctor's car by the Yorkshire Motor Car Company, Limited.

At the Uxbridge cycle sports to be held on the 5th inst., two motor-car events will be included in the programme. One a "bending race" to finish before a "brick wall," and the other an "obstacle race," to open and shut gates driving round the track.

THE Automobile Association, Limited, write us with reference to the recent accident to a De Dion voiturette owing to the axle breaking, pointing out that the axles on the cars imported through the German representatives of Messrs. De Dion Bouton are as strong as those imported direct from France, being in fact De Dion-made articles, and therefore the same in every respect. They also consider that it should now be taken into account that there are thousands of these little cars on the roads, and that one or two accidents should not condemn them all.

THE jury has made the following awards in respect of the recent motor-car competition in Paris:—First category, cabs propelled by spirit motors, gold medal, Peugeot No. 6; silver medal, De Riancey, No. 15. Second category, electric cab, gold medal, Krieger cars, No. 7 and 9; Silver-gilt medal, Jeantaud, No. 14. Third category, delivery vans, propelled by spirit-motors, gold medal, Brouhot, No. 4; and silver-gilt medal, De Dietrich, No. 17. Fourth category, electric vans, gold medal, Krieger.

THE Postmaster General of Canada has, it is reported, ordered three Locomobile steam cars for use in the postal service. Several tests had previously been made to demonstrate the utility of the vehicles. In one case, on three successive days, a car, driven by one man, collected the letters from thirty-nine boxes over an area of twelve miles and took them to the post office in the average time of 1h. 10min. With horse-drawn vehicles two horses and two men were required, and their average time for the service occupied 2h. 45min. Another very severe test was a forty-six miles' run over a road that varied between clay, sand, and other mixtures so vile that a horse team cannot cover it much faster than at a walk. The motor-car traversed it at an average speed of twelve miles an hour.

THE BAUER AND BLUHM MOTOR-TRICYCLE.

THE other day we had an opportunity of inspecting a new motor-tricycle which has just been imported into this country, and of which an illustration is given herewith. The feature of the machine is the location of the motor, it being placed not behind the rear axle as usual, but within the main frame; in fact, it is so built as to be part and parcel of the frame. The engine itself is of the vertical air-cooled single cylinder type, and develops 2 h.p. The illustration shows it to be fitted with the ordinary electric ignition, but in the machine we examined a magneto-electrical device was used to generate the electric spark. The sparking can be varied by means of a lever on the handle-bar to the extent that the engine can be made to run at maximum speed or one fourth or one half of the same. As regards the driving mechanism, a small spur-wheel on the motor-shaft is in gear with a large pinion mounted on a sleeve on the bottom bracket-spindle. Combined with this pinion is a chain-wheel geared by a chain to a small sprocket on the main rear axle. The pedals are connected with the latter by separate sprockets and chain, a free-

wheel clutch being provided at the bottom bracket. The combined petrol tank and carburettor is carried on the top bar of the frame and is claimed to be reliable in its operation. The driving pinions are completely enclosed, and the designers—two German engineers, Messrs. Bauer and Bluhm—claim that the location of the motor causes no inconvenience to the rider. The machine was built by a large cycle-making concern in Nurembourg, and has been introduced into this country by Mr. W. Taylor, of 54, Earlsfield Road, Wandsworth Common, S.W. It is claimed to be much lighter than the motor-trikes so far built, and is stated to be capable of attaining a speed of 50 kilometres per hour.

THE Motor-Car Company of Shaftesbury Avenue, W.C., inform us that they are now able to supply users of Renault voiturettes with any parts of these little cars for renewal purposes.

THE Eadie Manufacturing Company, Limited, Redditch, advise us that they have now opened London offices at 44-47, Bishopsgate Street Without, E.C., under the charge of Mr. J. McIntosh, whom they have appointed London manager.

THE Auto-Car Supplies Company, Limited, has been registered, with a capital of £20,000, to acquire the business carried on by O. C. Selbach at 12, Southampton Row, W.C., with the benefit of a contract with the Aachener Stahlwaarenfabrik, but not including the Miami Agency nor the lease of 12, Southampton Row, nor the vendors' office, furniture, and effects, and to carry on the business of engineers, cycle, motor-car, and component part manufacturers, etc.

AUTOMOBILES IN RURAL DISTRICTS.

THE century which is now approaching its end has witnessed the creation and the development of the railway—the most efficient of all means of transportation. The extraordinary effect which the invention and extension of railways have had upon our economical and commercial development need not here be dwelt upon. The world is covered with a network of steel tracks; and the railway undeniably occupies the foremost place among all systems of transportation. Powerfully as our commercial life has been influenced by the steam-railroad, the ideal method of transportation has not been attained, and cannot be attained by the railway with its pretentious system of stations and tracks.

Our transportation facilities have been improved chiefly for the purpose of accommodating the largest possible number of persons or quantity of goods, and of carrying them to their destination in the shortest possible time. The steam-railway has, therefore, supplanted all other means of conveyance and even degraded the horse-drawn vehicle to the position of one of its auxiliaries. The centralisation of traffic has now almost reached the end of its career. In civilised countries there is no necessity for building new railroads; and the development of the lines already in existence is confined chiefly to the construction of branch and auxiliary lines running to districts not connected with the main system.

The enlargement and extension of existing roads show the limitations of the steam-railway. As the *Automobile Magazine* points out, the railroad rarely meets the requirements of flat regions. Owing to the very small traffic, even the narrow-gauge line cannot be profitably operated between small rural communities; nor can its time-tables be always adapted to the needs of places not remotely situated from one another. For adjacent villages and towns a smaller, less pretentious system of transportation is evidently required, which, though less efficient than the larger railroad, is better suited for the purpose of establishing a profitable means of conveyance. Beyond a doubt automobiles are the best vehicles for the limited traffic of the country. They are destined to connect rural communities, not only with the nearest railroad, but also with one another. In districts where there is temporarily considerable passenger and freight traffic automobiles will be particularly serviceable. Summer resorts, for example, which during the warm season of the year are much frequented, are well-nigh lifeless during the winter. The building of a railway to such places would be unprofitable, but a line of automobiles running to and from the nearest railway would meet all requirements, and would, moreover, be much cheaper.

Mechanical traction without rails is free from the disadvantages attending the use of tracks and does not necessarily entail a loss in speed. The automobile is therefore destined to play an important part in the economic development of prairie communities. In order to strengthen our argument by means of a concrete example, we have but to mention the great possibilities of the motor-car in the improvement of our rural postal service. The high speed which can be attained on good country roads would certainly bring about a quicker distribution of the mails and consequently greater efficiency in the postal service.

If automobiles are to fill the wants of country districts, it is evidently necessary that roads be built which will be adapted to the needs of the new means of communication. The highways must be as level as possible; the grades must be few and slight. The roads should be kept in such condition that the vehicles would not be jolted and subjected to violent strains. In the delicacy of its driving mechanism the motor-carriage differs widely from the animal-drawn vehicle; and for this reason alone good roads are a necessity.

Not until the highways have been considerably improved will the full efficiency of the automobile be recognised in country traffic. Any positive opinion on the automobile is therefore premature. With the present lack of facilities on some of our country roads, it is no wonder that the motor-carriage has not always fulfilled the expectations of its champions.

But the building of roads, continues the contemporary already quoted, especially adapted for automobiles is not all that is required. It will be a matter of the utmost importance to reserve for the motor-vehicle the road upon which it is to run, and to divert to other channels the animals and vehicles which may hamper it. Special paths have been opened for bicycles; and there is no reason why automobiles should not enjoy similar privileges. A division of automobiles into light and heavy vehicles would also be advisable. If there were divided roads for light and heavy automobiles, the problem of maintaining the highways in proper condition would be considerably simplified. The light, swift carriage could then speed along without being suddenly checked by a slow, heavy truck. The provision of sidewalks for pedestrians has been one of the means of preventing a congestion of the traffic of large cities. A further improvement could be made by classifying the vehicles according to weight and speed.

Such a division of vehicles is even now possible on our roads. To be sure there are avenues and streets which are too narrow to permit a separation of light and heavy vehicles. But something must be done, with the rapidly increasing number of automobiles, to prevent the blocking of the way by cumbersome wagons. The obstacles to be overcome in attaining the desired end are not insurmountable, especially when it is considered how the building of roads has been modified in the course of time. The old Roman roads, which extended over half of Europe, as well as the roads built during the Middle Ages, were constructed in straight lines. They extended over the highest mountains; no hill was too steep nor valley too deep. Nowadays roads are curved and bent so as to avoid all steep inclines. Mountains are ascended by serpentine routes. The change has been brought about by the constantly increasing use of draft animals. The substitution of the circuitous route for the direct roads of the Romans will find a parallel in the construction of automobile highways, which will fill the wants of the future means of transportation.

Improvements in road construction go hand in hand with improvements in the vehicles of trade. Every step in the development of road-building has been due primarily to better means of transportation. Highways are gradually adapted to the demands of transporting vehicles, and only when adequate roads have been provided can these vehicles develop their full efficiency.

A SUCCESSFUL motor-car trip from Rome to Vienna has just been made by Cav. Bargnoni, of Rome.

WE learn that Messrs. Mayhew and Sons, of the Flour Mills, Church Road, Battersea, have just ordered a steam motor-lorry.

THE British and Colonial Motor-Car Company, Limited, are now arranging to supply motor-tricycles on easy terms of £1 per week for a year.

THE city of Mexico is said to be well adapted for motor-vehicles; but, at present, hardly any are used for business, just a few being run by wealthy inhabitants for pleasure.

A TRADE report from Coventry says that the motor industry continues good, and is likely to be all the winter, as the demand for cars of the best type is expected to be considerable next summer.

LA COMPAGNIE PARISIENNE DES VOITURES ELECTRIQUES (PROCEDES KRIEGER) is the name of a new company which has just been formed in Paris, with a capital of £80,000.

THE Nesseldorfer Wagenbau-Fabriks-Gesellschaft, of Nesseldorf, Austria, whose racing machine was illustrated in a recent issue, have just brought out a new four-seated car, fitted with a 9 h.p. motor.

WE have received a copy of the second edition of "Sketches of Engine and Machine Details," by Wallace Bentley, M.I.M.E. (Halifax: The Bentley Publishing Company). The work has been specially arranged for the use of engineers, draughtsmen, mechanics, and students, and that it is up to date is indicated by the fact that among the drawings given are several relating to the details of motor-cars.

FOOT RESTS FOR MOTOR-TRICYCLES.

UP to the present riders of motor-tricycles have been obliged to keep their feet in a position which is exceedingly tiring after a long journey. The accompanying illustration shows a type of foot rest which has been in use in France over eighteen months, and which is now being put on the English market by the United Motor Industries, Limited, of 64, Holborn Viaduct, E.C. It can be easily fitted to any

De Dion motor-tricycle in a few minutes. It is bolted round the frame at the bottom bracket, and, when not pedalling, can be turned down by the foot. A spring is fitted on each side so that it closes automatically when the feet are taken off. When the cranks are in the position as shown in the illustration the rest can be placed in the position required as foot rests. When it is necessary to pedal the rests can be lifted simultaneously by the feet.

La Locomotion Automobile reports that, acting on the advice of its doctor, the authorities of the Sanatorium at Allaud, Austria, have just ordered a 9 h.p. car for the conveyance of patients.

On the East Quay, Bridgwater, the Bridgwater Motor Company keeps a stock of petrol. The company has a large riding school capable of accommodating 200 motor-vehicles, to say nothing of a special pit and mechanics capable of effecting all kinds of repairs to motor-cars.

A COMMENCEMENT was made on the 15th ult. with the motor-car service between Aberdeen and Echt, N.B., referred to in a recent issue. The car, which left Market Street at eleven o'clock, could not accommodate all the passengers who desired to travel by it. The time-table of the new service is—Leave Aberdeen at 6 and 11 a.m. and 3.50 p.m. Leave Waterton 7.45 a.m. and 12.30 and 5.30 p.m.

A NEW two-seated steam car has just been completed by the Strathmore Automobile Company, of Boston, Mass. It weighs 1,400 pounds, and is driven by a steam motor rated at 6 h.p. It is intended primarily for city use, but is built with great strength and flexibility of frame, so that it can also be used for touring. A feature of the car is the elevated position of the rear seat. The boiler is hung fairly low, and the engine is apparently over the rear axle. The frame of the running gear is elevated considerably above the axles, and tubular braces extend to the outer ends of the front axle and to the bearings of the rear axle.

In addition to the large number of motor-tricycles that are being used for pleasure purposes in Paris, the commercial possibilities of the machines are being rapidly realised, and any number of the storekeepers are having attached, instead of the two-wheeled pleasure trailer, a delivery attachment which can easily carry five hundred pounds. The fact that while the business can be advertised on the delivery box, the trailer can be detached at night and the machine used as either a pleasure tricycle, or with a pleasure trailer attached to the rear, makes the combination a useful all round machine.

A COLLISION AND THE SEQUEL.

At the Bournemouth County Court, before his honour Judge Phillbrick, Q.C., a case was entered for hearing in which Mrs. Llewellyn, of Tarrant Keynstone, near Blandford, sued W. W. Warn, of Poole, for the sum of £5, claimed as damages arising out of a collision alleged to have been caused by defendant's motor-car. It was intimated that the case now stood over, by mutual consent, until October.

MOTOR-CAR PROSECUTIONS AT BOURNEMOUTH.

At the Bournemouth Police Court, on Friday last week, Henry Budden, Wm. Rushton, Frank Marriner (in the employ of Mr. Bell), Frank Leid (in the employ of Mr. J. S. Norman), and Edgar W. Collett, motor-car drivers, were summoned for excessive driving. Mr. H. S. Dickinson, who appeared for Rushton, Budden, and Marriner, asked that Rushton's case should be taken first. This the Bench agreed to, and on the defendant being charged, Mr. Dickinson handed in the summons and pointed out that the date of the alleged offence was not on it, and that, therefore, he did not know what date he had to answer to. The Clerk: You say you are misled? Mr. Dickinson: Absolutely. The Clerk said the only course was to adjourn the case. Mr. Dickinson said that in that case he must ask for expenses. It was grossly unfair to him, as he was bound to attend when summoned. The Clerk: You say that defendant was unaware of the date? Mr. Dickinson: Undoubtedly. You see we have no knowledge of the date. Superintendent Foster said the defendant was aware because the sergeant accosted him. He asked for the summons to be amended. It was decided to take the cases under the circumstances in the order the summonses were issued, and Henry Budden was called. The evidence of P.C. Baugh and Sergeant Thomas was that they took up stations at measured distances, the former at Stafford Road and the other opposite Fippard's Bakery. Baugh signalled when a car passed him, and Thomas with a stop watch took the time occupied between the points. The speed of the car was ten miles, four furlongs, and ten yards an hour. In reply to Mr. Dickinson, Baugh said he did not take much notice of the speeds, but he was of opinion it was dangerous in view of the heavy traffic. Sergeant Thomas said that the traffic was heavy, and in reply to Mr. Dickinson, said though he thought the speed was dangerous, he did not pull up the defendant, but let him go on. Mr. Dickinson, for the defence, said that he had been on a motor-car that day for the first time, but he was convinced that they could pull up within two yards or less, even going at a fast pace. With an ordinary carriage this could not be done, and what would be dangerous with it would not be so with a motor-car. As long as they were properly driven and did not exceed the twelve miles an hour as laid down by the Local Government Board, and were driven with proper precaution, he asked the Bench not to convict. He called the defendant, who said he had no recollection of the date, but had never had any complaint, nor had he endangered anyone. Going at twelve miles an hour he could pull up in about two lengths, and if at a less speed could do so quicker. He heard nothing about the complaint till the next day. Mr. Dickinson said the summons was not issued till August 20th. In reply to the Bench, defendant said there was no fixed time-table. Mr. Edward Arthur Bagot, a gentleman residing in Parkwood Road, who volunteered evidence for Mr. Bell, said he had ridden as often as any one on the cars, and on many occasions with Budden. He had always found him and the other drivers very careful. That very morning the car had been tested with a full load going down Boscombe Hill at twelve miles an hour, and the car was pulled up within two lengths, and on another time at a length and a-half. On the level the car pulled up within half a length. The roads were slippery with rain. The Bench convicted, the chairman saying there was little doubt the car was going faster than was perfectly safe considering the traffic, but he did not think it a serious case, and would only inflict a fine of 1s., and costs 12s. Frank Marriner was next charged. Mr. Dickinson said that the summons was not dated, and said he would agree to an adjournment if the costs were paid. Superintendent Foster said the defendant was told about it the following day. The Bench decided to adjourn the case till Wednesday next. Mr. Dickinson then said he would withdraw the objection if the Bench would not give him costs, but it was a monstrous thing. The evidence in this case was that the speed of the car was twelve miles six furlongs and 160 yards an hour. Marriner was fined 1s., and 11s. costs. The other cases were disposed of as follows:—Wm. Rushton, fined 1s. and 9s. costs; Francis Leid, 1s. and 9s. costs; Edgar W. Collett, 1s. and 9s. costs. Superintendent Foster stated that these prosecutions had been instituted in consequence of complaints from the inhabitants.

A STRANGE-LOOKING steam delivery wagon has lately been built by Mr. S. H. Barrett, of Springfield, Mass. One of the features of the car is the vestibule with door directly in front. The door has a glass window in a frame which can be closed by raising up, and thus protect the driver in bad weather. The boiler is of the tubular type, with an automatic fuel controller. The entire mechanism is fitted below the body of the vehicle, thus admitting of the use of any style or type of van body.

THE Motor-Car Journal.

VOL. II.]

LONDON, SATURDAY, SEPTEMBER 8, 1900.

[No. 79.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

RECOGNISING the interest of the automobile section of the Paris Exhibition, the Rt. Hon. J. H. A. Macdonald, the Lord Justice Clerk of Scotland, has suggested the possibility of arranging an automobile trip for, say, a week, including four days in Paris. In the event of such an excursion being organised there would probably be some who do not own a car desirous of going, and they could combine to hire a good one for the journey. The time suggested is anywhere between the 15th inst. and the 8th prox., and the secretary of the Automobile Club will be glad to hear from any member willing to take part in such a pleasant little expedition. We may add that, according to Parisian correspondents, there is no run on the hotels just now and that it is quite easy to get accommodation.

The Motor Racing Track.

IN our issue of June 2nd we brought forward the idea of a great motor track, and in referring to the popular meet at the Ostend Motordrome (a track with a circumference of close on two miles) the *Daily Express* says it revives anew the discussion as to the feasibility of creating some such track in England. Continuing, our contemporary adds:—"Road racing in England is obviously impossible. A big track, however, if only the ground could be secured and the capital raised, would provide a means of indulging in a most exciting form of sport, both to competitors and spectators alike. Even at the Crystal Palace it is by no means unexciting to see motor-cycles at work, but on a track of great width and of such large circumference as to eliminate all danger at corners, even big cars might race at top speed with impunity. And it must be borne in mind that a competition of any kind which may be monotonous at medium speed becomes distinctly exhilarating when the speed exceeds the normal. If such a track ever comes to be made in England the public may rest assured that they will not find the proceedings dull."

A Rumour Revived.

A LONDON correspondent of a provincial paper says that the Home Secretary is considering restrictions to be imposed upon the rate at which motor-cars may travel on the highways. Some serious complaints have been made to the police, including one from a peer member of the Cabinet against a member of the House of Commons. Several such paragraphs have been going the round of the press, and it is highly probable that questions on the speed of motor-cars may be addressed to the Parliamentary candidates in some country constituencies at the general election. But we do not think there is anything but mere rumour in the idea.

A Political Tour by Motor-Car.

MEANWHILE some candidates are preparing to utilise the motor-car in their political campaigns, and Mr. A. Williamson, to whom we made reference last week, has just completed a political motor tour. This was through the constituency of North Ayrshire, and terminated on Saturday. The distance

covered was about 350 miles, approaching an average of sixty miles each day, a feat that would have been impossible had the ordinary means of locomotion been employed. Mr. Williamson on this occasion held no formal meetings with the electors, but in many of the towns impromptu meetings were got up. The main object of the trip was to find out the various interests of the constituency, and this he was able to do in a thorough manner by the rapid means of travel at his disposal enabling him to get in contact with the electors in every corner of the division.

A Disputed Insurance Claim.

WE have not yet heard the last of the accident to Mr. Rucker's car reported some time ago. It will be remembered that in avoiding a timber-laden wagon at a nasty part of the road, the motor-car was turned suddenly on a greasy surface. Side slip occurred, a tire was ripped off, and the car overturned, smashing the petrol tank, and causing the vehicle to catch fire. Mr. Rucker claimed damages to the extent of £150 from the Horse, Carriage and General Insurance Company, but this is being resisted on the ground, we believe, that the policy exempted claims on account of fire from its operation. Mr. Rucker's contention is that the accident was the cause of the damage, and that the fire was an effect, not the cause, of the accident. It is probable that the matter will come before the court.

The Storage of Petrol.

AT the Hove Petty Sessions two cases have been heard against local traders for keeping on their premises a larger quantity of petroleum spirit than three gallons without a licence. It was clear from the evidence that they thought they were acting within their legal rights in storing larger quantities, but that did not prevent fines and costs being inflicted. Traders cannot be too careful in this matter, and should take care they have a licence if they intend to supply the wants of motorists with regard to petrol.

The Madelvic Works.

THE well-known Madelvic Motor Works at Edinburgh have been purchased by Stirlings, Limited, of Hamilton, N.B. This purchase will probably arouse widespread interest, as the works are of considerable extent, and have, we believe, a motor track in addition to the ordinary equipment of an engineering works.

A Scotch Appointment.

AMONG the Scotchmen who are frequently touring in the northern part of the kingdom is Mr. John Love, of Kilmeny, Kirkcaldy, the late managing director of the Edinburgh Auto-Car Company. He is to be seen on one of the Motor Manufacturing Company's Iveagh phaetons, and having been appointed representative in Scotland of the makers of that vehicle, will be glad to give interested correspondents a trial trip at any time. This will be a convenience to northern readers who have not the opportunity of seeing the car at the Motor Manufacturing Company's show-rooms or works.

The Napier Car in France.

THE accompanying snapshots are interesting reminiscences of the recent visit of the 16 h.p. Napier car to France. The first was taken outside Lord Llangattock's house at Knightsbridge, and shows Lady Llangattock and the Hon. C. S. Rolls on the car. The second illustration was obtained on the way from Paris to Havre. Mr. Rolls was then driving, and while he was getting

some information with regard to the road Mr. S. F. Edge disappeared, ultimately reappearing with a supply of fruit with which to beguile the next stage of the journey. The second pair of photographs is associated with Mr. M. S. Napier, who is very seriously examining the car in Paris. This was in the early morning, soon after a water-pipe had broken, and it was only just daylight when the photo was taken. In the other view Mr. Napier is distinguished by the white handkerchief round his head, the car having been pulled up on the road between Havre and the French capital. In the last of the series Mr. Rolls is walking round the car to get up into the driver's seat.

Brakes Firing.

THE recent adventure to Lord Wolverton, arising from the firing of the brakes, has called renewed attention to this question. Many attempts have been made to get over the difficulty, and in the "Napier" car the brake drums are filled with water to prevent them heating to such an extent as to burn the brakes. Moreover, Mr. Edge informs us "if the

carriage had no brakes at all it is possible to stop it down hill by merely switching off the electric current to the engine, which at once transforms the engine into such a powerful brake that it will stop the car on the steepest hill quite independent of the band brakes."

A 50 h.p. Napier Motor-Car.

MR. S. F. EDGE, in a letter published in the correspondence columns of the *Horseless Age* of New York on the subject of the design of motor-cars, remarks that: "I have personally tried nearly every type of automobile, with the engines set in all kinds of positions, and I have come to the conclusion that ordinary engines set in the front of the car behind the front axle gives one the most convenient place for them. In front of the engine itself one has the radiators, then, just under the dash board, comes the flywheel, behind this comes one's arrangement of gearing, then comes the cross-shaft with the chain wheels on it, and then, away at the back, the rear wheels. The result of this is that, whilst you have a very expensive type of car to manufacture, you have an exceedingly effective one; everything is absolutely sealed against dirt or wet, and it makes no difference how filthy the roads are, you can run hour after hour without being affected in the slightest. As nearly as possible the car balances absolutely between the centres of the two wheels." In the same letter Mr. Edge makes the announcement that "We are building some 50 h.p. cars for the Gordon-Bennett Race for next year." The advent of these powerful vehicles will be awaited with interest.

Motors and Clean Streets.

WITH praiseworthy persistency, Mr. Shrapnell Smith continues to inform interested persons of the value of motor vehicles in connection with municipal work. Elsewhere we publish a paper he has just read at a conference at Salford, following which this resolution was adopted:—"That this Annual Conference of the Cleansing Superintendents of Great Britain, assembled in Salford this 30th day of August, 1900, is of opinion that efficient motor vehicles justify their adoption for street watering and dust removal, and this meeting urges municipal, urban, and other authorities to consider their adoption."

Motor Fire Engines.

Now that some of the more enterprising vestries have put on the streets motor-water-carts and motor-dust-carts, it is surely time, suggests a contemporary, that the fire brigade should turn their attention to the advantages offered by motor-fire-engines. It is undeniable that these would travel faster and that they would take less time to start for their destination than the ordinary engines. They could be so constructed as to enable them to be drawn by horses should the motor become suddenly deranged. A motor fire-escape could also be easily constituted, and such an appliance might lead to the saving of many lives. There is no doubt that the future will see many improvements as the result of motor power being applied.

From Edinburgh to York.

THE road from Edinburgh to York is one of the best main roads in the country, although the surface is rather bumpy in Musselburgh, Haddington, Berwick, and Alnwick, in the colliery district near Newcastle, and between Thirsk and York—as was evident during the 1,000-mile Trial. Those who contemplate invading England from the north by motor-car had better provide themselves with a copy of the "Great North Road" map, Part 2, which Messrs. Gall and Inglish have published. The plan of this series of maps is now so well known that further description is unnecessary; suffice it to say that the present map is quite up to the standard of its predecessors.

Attempt on a Record.

WE believe it is the intention of Mr. Charles Jarrott to attack the present motor-tricycle record on the Crystal Palace track. Provided the weather is not too unfavourable, the attempt to do forty miles inside the hour will probably be made one day next week.

Leaving Vehicles Unattended.

IN a case heard at the Ramsgate Police Court the chairman of the Bench said he hoped motor-cars would not be left in the road unattended. We hope that the hint to motorists will also be observed by the drivers of horse-drawn vehicles in Kent and elsewhere. In country districts it is quite common to find vehicles unattended by man or boy. Tradesmen delivering parcels at houses are in the habit of leaving their horses while taking goods to the house. Should a motor-car or a coach-and-four with a horn briskly playing come along the animal may get excited and bolt. Of course everybody but the negligent man in charge is blamed for frightening the horse. This happens every day, and as practically all these carts have a boy as well as a man in charge there is no reason why those who leave vehicles unattended should not be proceeded against, for instead of the boy looking after the horse he is generally attending to other customers.

Teams in the Road.

IN rural districts the same evil assumes another and even more awkward phase. Often when touring in country localities we have seen two or three teams of three and four horses each outside village inns. The drivers are refreshing themselves, and the horses, left alone, get into the middle of the road, or on the wrong side. When the motorist comes along and "teuf teuf" sounds out clearly there is a general scamper of the horses, a rush of the drivers from the inn, and considerable departure from the classic purity of the English language. When the drivers have done swearing at the horses they probably hurl obnoxious epithets at the unoffending and waiting motorist. Surely if the police were anxious to regulate traffic on the highway they would find a good outlet for their service in warning drivers against leaving teams unattended and taking proceedings where their warnings are disregarded.

Stones on the Highway.

WHILE referring to this topic we would refer to another objectionable feature of rural traffic in connection with which some county authorities are, we are glad to see, taking action. This is the habit of carters and others placing large stones, and even bricks, on the roadway behind the rear wheels of their wagons on reaching certain points on a hill. We do not condemn them for that, and motorists have often found such a course useful when touring; but what we do abhor is the thoughtlessness that leaves such stones lying about. There are already sufficient things on the roadway which might properly be swept away without adding huge stones and half bricks to the number. While at the Bear Hotel, Devizes, last week, we heard that the local police intend to take action in the matter, and the attention of the authorities in other counties should be called to the dangerous practice, a practice that threatens danger to every vehicle using the highway.

Porlock Hill Again.

THE last words we heard at the Plume of Feathers Hotel, Minehead, were from some huntsmen who were discussing the motor ride up Porlock Hill. Only those who have spent some time in the district can have an adequate idea of the interest aroused in automobilism by the recent successful trip up the steep gradient. Everyone talked of the achievement, and every little boy recognised the remarkable character of the feat. Several times they shouted as we passed, "There's the motor that went up Porlock." We spent several days in the neighbourhood of Minehead, and travelled about a good deal, meeting large numbers of horsemen going to and from the hunt. With persuasion on the part of the riders and caution on our own, no unpleasantness occurred. In many cases the horses were ridden by ladies, and then we invariably led the horses, the ladies always thanking us brightly, and not seeming to mind the experience at

all. Probably the ride up Porlock Hill had something to do with the feeling of confidence.

Minehead to Devizes.

OUR return to town was by way of Williton and Nether Stowey to Bridgewater, twenty-six miles—an undulating road showing glimpses of the bay—and through the Quantocks. Thence on a dismal road to Glastonbury, a distance of fifteen and a-quarter miles, where we had luncheon at the Old Pilgrim's Inn. From that ancient place we went, *via* Wells, Frome, and Trowbridge, to Devizes, where we made a stay at the "Bear." Our day's journey totalled 88 miles. Perhaps the most notable descent was that into and through Frome, from which we had a fairly stiff rise to continue the journey.

89 Miles to London.

A MOST inauspicious morning was that of the last day of our tour. Not only was there a chilliness in the air, but the rain fell in torrents. Shortly after nine a.m. the start was made, and we reached the "Bear" at Maidenhead a minute or two before one—having travelled sixty-three miles without a single stoppage. Shortly after we had crossed Marlborough Downs the rain stopped, and the roads, which had been in a sticky and greasy condition, became soft and heavy for the rest of the journey. After lunch the short run to London was soon concluded, and we had the pleasure of reaching our habitation after an absence of eight weeks, during which time we had not had a single wet day, excepting on Bank Holiday, when it rained up to 10.30 a.m., and afterwards blew with the force of a

MOTORISTS AT SEA.

gale. Even this inconvenience had its advantages, for in the afternoon we were able to drive to Gurnard's Head, Cornwall, where we photographed some very grand seas. Our M. M. C. Panhard was not always with us, but when it was, we had it in constant use, and daily excursions and trips were made. It was even used for the morning bathing trips. The car never gave us any trouble, and always ran smoothly and quiet, proving itself a reliable vehicle throughout the holiday.

Some Experiences.

OF experiences we had singularly few. The natives of Somerset and Devon—although their horses may have been troublesome—did not vent their displeasure on the motorist's head. But, alas! as soon as we had crossed the border into Wiltshire a different race of people was met. In one place a drover was leisurely walking behind two beasts that were proceeding along the road, grazing as they went. Suddenly to our astonishment he held up his hands and shouted "Stop, stop." Seeing no reason why we should do so we proceeded until we came alongside the man, who demanded to know why we did not stop when he held up his hands—surely a new rendering of the Act. On another occasion we were proceeding up a somewhat

steep hill on the second speed. A long way in front was a trap with three passengers. We sounded our horn, whereupon one of the men jumped out and frantically waved his hand for us to stop. We gradually crawled forward until we could hear what the man said. He kept on repeating, "Go back, go back." Needless to say we did nothing of the kind. The other two men were standing up in the trap, and we urged them to get out and hold the head of the horse. This they did at last, hanging round the horse's neck, while we proceeded on our way. The worst that we then heard was that they would report us—when and to whom they did not say!

An Incident on the Ascot Road.

ABOUT three months ago the Earl of Carnarvon's motor-car was being driven from Ascot to London when it met a vehicle drawn by a horse, which was either inadequately trained or had a driver who allowed it to get beyond bounds. An incident took place which was unpleasant for the horse and unsatisfactory to its owner. The latter decided to claim damages against the Earl, who has placed his case in the hands of Mr. T. W. Staplee Firth.

Touring in Cornwall.

MENTION on a previous page of the brake on the Napier car makes opportune the publication of a photograph of what is, we believe, the first finished Napier car. With this Mr. S. H. Pearce has been touring in Cornwall. He has been enjoying a long tour in that delightful county, and regards the roads as excellent for motor-driving—provided the car has sufficient power. It is little use taking a low-powered vehicle to Cornwall, if it is to be thoroughly explored. Unfortunately the nervousness of drivers of horses is as noticeable in Cornwall as elsewhere, and it is no uncommon thing for the drivers to get from their carts and hold the horses' heads, fuming all the while, and wondering why motor-cars should be permitted to use the roads at all.

Lost and Found.

A MOTOR-CAR is an attractive vehicle, though we should have imagined it to be a difficult article to steal. The other day someone removed a 6-h.p. Knightley Victoria Daimler car from the show-room of the Discount Motor-Car Co. in Clock Terrace, High Road, Cricklewood. Now, unless a man understands the working of a motor-car it is a rather strange article to take away, and that fact seems to have dawned upon the gentleman who assumed charge of this particular car, for it has since been found on the roadside at Bushey Heath with the front axle broken and other damages. Probably if the person who removed the car will again call at Cricklewood the manager will instruct him in its proper management and manipulation.

Motorists' Garments.

WE learn that some discussion is going on among American owners of automobiles as to the "correct" raiment in which they should appear on their vehicles. This is a matter that should be easily settled, if they will apply a little common sense to the matter. It was a debateable point in this country some time ago, and many automobilists adopted something between a yachting costume and one that would have done credit to Crusoe's man Friday. Now the peaked cap has gone, and a cloth-lined overall will probably take the place of the furry coats of two or three years ago. Comfort and good sense soon settle all such problems; so New Yorkers need not be alarmed at their supposed difficulties with regard to attire.

A New Winter Coat.

Now that the winter is approaching the provision of warm clothing will be a matter of concern to all motorists, and in this Messrs. Hoare and Sons, of High Holborn, E.C., are well to the fore with a very serviceable overcoat. This is of full length and size, and has nearly a dozen capacious pockets,

together with a small pocket for the watch on the outer sleeve. They have all been placed in the most convenient positions, and the trouble of stowing books, papers, etc., which has been a real one to motorists, is entirely obviated by the adoption of this coat. We have just obtained one in a dark grey cloth—one of the most suitable colours for winter riding—and this is stoutly lined, so that winds can blow and the wearer still keep warm. An ingenious arrangement for securing the warmth of the neck has been introduced, and altogether Messrs. Hoare and Sons are to be congratulated on the way in which they have thus sought to serve the motor-world. In coat-architecture their new garment for automobilists is certainly excellent in design and workmanship.

Mr. C. G. Wridgway.

OF the several well-known personalities in the motor-world who left this country for the United States early in January last, all except one have now returned to England. The exception is Mr. C. G. Wridgway, who appears to have settled down on the other side of the Atlantic, for, from the last issue to hand of the *Horseless Age*, we learn that the recently-formed De Dion-Bouton "Motorette" Company, of Brooklyn, New York, have secured him as their travelling representative. Mr. Wridgway will presently start from Albany and make a trip through the Mohawk Valley, visiting Troy, Schenectady, Utica, Syracuse, Rochester, Buffalo, Dunkirk, Erie, and Cleveland. From there he will go down through the carriage district of Ohio, and then either on to Chicago or back through Pennsylvania. It was on the racing track that Mr. Wridgway was best known in England, and his motor-tricycle riding at the Crystal Palace last year will long be remembered by those present. Apart from racing, however, he showed great business acumen, and we congratulate him on his new appointment, which should prove advantageous to both parties.

Helpful Work.

THE useful work of the Commons and Footpaths Preservation Society must commend itself to every automobilist as well as to pedestrians and riders generally. The annual report of the Kent and Surrey Committee of the Society which has just been issued is a capital record of work done, and of local activity at Haslemere, Guildford, Godalming, Horsham, Coulsdon, Reigate, Tonbridge, Charlton, and Chelsfield. The committee point out that the work of the society is permanent in character, for when once a footpath is established or an open space preserved in the ordinary course of events neither can be lost to the public. Those who assist the committee's efforts are therefore assisting a movement the results of which are of benefit for all time. In order that the work may be effectually carried out, the committee desire:—(a.) To enrol as many residents in Kent and Surrey as possible as members of the society. (b.) To enlist the services of riders or pedestrians who know any parts of the counties well, who will mark on sheets of the Ordnance map, supplied by the committee, the footpaths now open to the public, the roadside strips still unenclosed, and the commons. (c.) To enrol corresponding members who will be prepared to allow the secretary to ask them to obtain for him any information he may need in their neighbourhood, should questions arise as to enclosure of open land or obstruction of paths. (d.) To establish in all urban centres in Kent and Surrey local committees to whom any cases sent direct to the committee for advice and assistance may be referred.

Motor-Cars for Hot Weather.

COOL breezes during the past few weeks have caused us to almost forget the great heat of the days of July. In the hottest days a seat on a motor-car was, perhaps, the most enjoyable situation. A lady at Chartres, writing to an English friend, says that during the heat experienced at that place, the only resource to which they could fly was the motor, as its quick motion seemed to give them a little air. Not only was that the case, but by means of linen curtains and glass panels some protection was afforded from the dust.

The First Finished 8-h.p. Napier Car.

MR. S. H. PEARCE ON TOUR IN CORNWALL. (See opposite page.)

AN ADVOCATE OF ELECTRICAL VEHICLES.

MR. WHITNEY LYON, a prominent member of the Automobile Club of America, is an enthusiast over electric carriages. He has recently returned from France, where he has been studying automobilism, and although he found that the electric type of machine is not popular in that country, Mr. Lyon is as strong a champion of this type as ever. "France leads the world in speed machines," considers Mr. Lyons. "Immense road locomotives built at unlimited cost, and carrying enough petrol for an uninterrupted run of 300 or 400 miles, are all the rage at present. They are about as heavy as our road rollers and make as much noise as a threshing machine, but they certainly have speed. They cost as high as £3,000. They do not use electric carriages so much in Paris as in New York, but they will when they know them better. All the different types of machines have their own field, and I am willing to admit that at present the electric vehicle is not so suitable for a long-distance tour as is the petrol or steam carriage. Still, I think the field of the electric vehicle is enlarging. A year ago the best storage batteries would propel a carriage a little

over thirty-five miles without re-charging. Now an electric phaeton can go sixty miles, and the system of storage is being constantly improved. In time, the necessity for recharging will not limit the touring capabilities of the electric vehicle, because greater efficiency in the batteries will give them a longer radius for a single run, and as charging stations are being established everywhere, it will be easy to renew the motive force at convenient stopping places. I have never had any trouble with my carriage from the power giving out at a distance from a charging station.

"For town use there is nothing to compare with the electric machine. There is no odour, no boiler, no fire; it is quickly and easily operated and controlled, and is much superior in speed qualities to other types. I have driven about 6,000 miles in my car during the past year, and it has never broken down, and has never had to be towed home. The battery, which was supposed to lose 25 per cent. of its effectiveness by the end of the year, from wear and tear of the parts, has never been repaired, and has not deteriorated 5 per cent. from its former efficiency. The only care it has had is the refilling with sulphuric acid and water. During the year repairs have amounted to about 22dols., and the average cost of running it has been a little over 4dols. a month. Another great point in favour of the electric vehicle is its cleanliness."

THE CRÉANCHE PETROLEUM-SPIRIT MOTOR-CAR.

WE are able this week to illustrate still another of the many types of light motor-cars recently introduced in France. This is the Créanche of the Société des Voiturettes Créanche, 7, Rue Brunel, Paris. The car, which, as will be seen, takes the form of a three-seated phaeton, possesses

FIG. 1.—THE CRÉANCHE CAR.

one or two novel features, as will be gathered from the following brief description. The motor—a De Dion—is of 4 h.p., and is fitted with water-jacket and electric ignition. The diameter of the cylinder is 80 mm. and the stroke 95 mm.; two flywheels are provided. The engine is located on the fore part of the frame, and is mounted, together with the water and petrol tanks, the carburettor, and the silencer, on a sliding bed-plate, the object of which is referred to below. On the motor-shaft (see Fig. 2) is a pulley whose width is twice that of the belt which connects the motor-shaft to a counter-shaft, the latter carrying three pulleys. The two outer ones of the three are loose on the shaft; one is in rigid connection with a spur wheel,

FIG. 2.—PLAN OF CRÉANCHE CAR.

while the other can be made rigid with either of two pinions. These three spur wheels are always in mesh with corresponding pinions on the differential shaft, the power being transmitted through the pulley on which the belt may be and its corresponding pinions. Three forward speeds—8, 16 and 32 kilometres per hour—as also a reverse motion, are provided. From the intermediate shaft to the rear road wheels the power is transmitted by the

usual duplicate sets of sprocket wheels and driving chains. To cut the motor out from the transmission-gear, in case of blocks in the traffic, etc., no friction clutch is employed, but advantage is taken of the method adopted of mounting the motor and its accessories on a sliding bed-plate; the latter can, by means of a lever within easy reach of the driver, be drawn a slight distance towards the driver, which has, of course, the effect of causing the driving belt to run slack. A reverse motion to the controlling lever pushes the motor away from the driver, and so tightens the belt. The frame of the car, which is built up of steel angles and wood, is rectangular in shape, and is suspended on the axles by plate springs. The wheels are of the cycle type, and are fitted with pneumatic tires, while the steering is controlled by a sloping hand-wheel. Ample brake power is provided, there being a band brake on the intermediary differential shaft and cord brakes acting on drums on the hubs of each of the rear road wheels. A detachable handle is provided for starting the motor while the vehicle, which is about 6½ ft. long, the width between the wheels being 3 ft. 7 in., can be fitted with a hood, if necessary.

THE SCHEELE ELECTRICAL MOTOR-WAGON.

WHAT is probably the heaviest electrical motor-wagon in Europe has lately been turned out from the works of Herr Heinrich Scheele, at Cologne, Germany. The vehicle, of which an illustration is given on page 457, is stated to be capable of carrying loads up to 5 tons at a speed of from 4 to 5 miles per hour and of climbing gradients of from 8 to 9 per cent. The wagon is driven by two 6-h.p. electric motors geared direct, one to each of the rear wheels. The electrical energy is supplied by a battery of 44 accumulators cells, one charge of which is said to be sufficient to run the wagon a distance of from 20 to 25 miles. The controller is adapted to give two speeds forward, one reverse motion, and electric brakes. Tire brakes acting on the rear wheels are also provided. The makers claim that proprietors of large industrial establishments equipped with electric generating plants will find electric wagons an economical method of freight transport.

THE Comtesse de Béarn has just ordered a Gardner-Serpollet steam-car of 8-h.p.

THE AUTOMOBILE MANUFACTURING COMPANY, LIMITED, of North Street, Manchester Square, London, W., are, we learn, about to open extensive show rooms in Long Acre, W.C., where both petrol and electric vehicles will be on view. They have already about a dozen Columbia electric cars on hand to which they are fitting their own batteries.

THE Waltham Manufacturing Company, of Waltham, Mass., U.S.A., have lately turned out their first motor-bicycle. Ridden by Champion, the French automobilist, a five-mile exhibition was given on a local track, a mile being covered in 1min. 26½sec., and five in 7min. 16½sec.—an average of 1min. 43sec., and 40sec. better than the tandem-paced American record. The bicycle weighs 120lb., has a 48-in. wheel-base, 1¼ in. tubing is used in the frame, and it carries a supply of oil for fifty miles. The engine is affixed to the lower-cross tube of the frame, and the machine is driven by a flat leather belt, working on a pulley on the end of the motor shaft, and engaging in a pulley or grooved periphery of a metal rim 4in. smaller in diameter than the wood rim of the rear wheel, to the left side of which it is secured. To tighten or loosen the belt, an idler or lever is provided, by means of which the belt may be also thrown entirely out of gear, thus permitting the bicycle to be propelled by the pedal power alone, a free-wheel, and a rear band brake being also employed. The bicycle which Champion used was fitted with a 3¼ h.p. Aster motor, but in marketing the machines, the Waltham Company will employ motors of different powers—high powers for racing purposes, lower powers for road use, but powerful enough to climb any hill that may be encountered.

PARIS EXHIBITION NOTES.

(FROM OUR OWN CORRESPONDENT.)

(Continued from page 444.)

SO complete a description of the "Rochet" vehicle has recently been given in the columns of the *Motor-Car Journal* that it is useless to enter into details, and I will therefore but briefly enumerate the types of automobiles which are to be found upon the company's stand at Champ de Mars. The largest car is one of 12 h.p., and built for four passengers, two being placed in front and two carried upon a dickey behind. Two 6 h.p. carriages come next on the list. Both are of the "tonneau," or wagonette, type, and each carries four persons. A tri-cycle and a quadricycle, both fitted with De Dion motors, complete the list of automobiles exhibited, and it is of special interest to remember that it was these two types of machines which accomplished such extraordinary performances in the exhibition "Concours de Moto-cycles," which took place from June 18th to 25th under the direction of the French Automobile Club. Upon that occasion the quadricycle, with two persons up, covered 800 kilometres at the expense of only twenty-nine litres of petrol. The tri-cycle completed exactly the same journey on a consumption of but twenty litres. Truly remarkable performances, and accomplished simply by means of the "Rochet" carburettor, for the motor used was the De Dion.

MM. Mildé et Cie., 60, Rue des Renaudes, Paris, exhibit three of their well-known electric cars. A victoria carrying both motor and accumulators suspended under the driver's seat, and a four-seated *vis-à-vis* car similarly disposed are the smaller vehicles, while the heavier class is represented by a large omnibus. It is more especially in the field of heavy electric vehicles that MM. Mildé et Cie are prominent, and one sees daily in Paris a number of their delivery vans at work.

One finds an old friend in the shape of M. Léon Bollée's three-wheeler, which, with a *voiturette*, are the sole productions shown by the famous constructor of Le Mans. It is really extraordinary what popularity this type of automobile had, and how quickly the craze for it died out. To-day one never sees one, and where they have disappeared to I am at a loss to know, unless side-slips have carried them all off.

M. Louis Gautier exhibits a frame carrying a large single-cylinder motor, and fitted with his patent transmission gear, by means of which all chains, belts, and intermediary gear are suppressed. A single lever commands the forward and reverse motions and the change of speeds, and looking at the frame one is struck by the ingenuity displayed in crowding so much machinery into so small a space. The ordinary purchaser of a motor-car would be terrified by the sight alone of such a collection of gear and wheels and things generally as are attached to this frame.

A provincial firm which is well to the front in the construction of motor-cycles and motors for light vehicles is that of MM. Chavanet, Gros, Pichard et Cie., of Saint Etienne (Loire). Their display at Champ de Mars is fairly extensive, and comprises a 2½ h.p. roadster tri-cycle, a 3½ h.p. racing tri-cycle, and a quadricycle fitted with a 3½ h.p. engine and provided with two speeds. All these machines carry the "Auto Moto," and there are in addition the following engines of that type exhibited:—Two 2½ h.p. and two 4½ h.p. air-cooled, and two 4½ h.p. water-cooled. A collection of well-made axles, bearings, hubs, and

other motor-cycle parts go to make up a really interesting exhibit.

MM. Felix Brosse et Cie., of 22, Rue Béranger, Paris, exhibit a neat little *voiturette*, but, unfortunately, in an unfinished condition, for no controlling levers whatever are to be found. It is designed to carry two persons; it is fitted with wheel steering and carries a small radiator right in front. Between this radiator and the splash-board, and protected by a screen, is a 3 h.p. De Dion. From an artistic point of view the screen is unquestionably an advantage, but it entirely shuts off the motor from the current of cool air which would otherwise play upon it. A motor-cycle with De Dion motor and a number of ordinary cycles are also shown by this firm.

The three vehicles exhibited by MM. Cambier et Cie., 139, Rue du Faubourg de Roubaix, Lille-St.-Maurice (Nord), are similar in one respect—they are all covered in. There is a two-seated *coupé* with a single seat in front for the driver, exactly similar to the car constructed by the Daimler some three years ago. Then there is a back-to-back dog-cart, the front seat of which is protected by a wooden hood, and, finally, there is a comfortable-looking omnibus. One misses from this stand an example of the Cambier small car, for it is a smart little vehicle. It carries, too, an air-cooled, single-cylinder, horizontal motor developing between 5 and 6 h.p., in itself somewhat of a rarity.

MM. Paillet, Caron et Cie., 48, Rue Saint-Ferdinand, Paris,

show a neat *voiturette*, carrying in front one of their 5 h.p. air-cooled motors. This engine has a couple of cylinders, and its force is transmitted direct by bevel pinions, to the entire exclusion of belting, chains, etc. Three speeds and reverse are provided. The price is £240. The firm also exhibit a tri-cycle fitted with one of their 3 h.p. single cylinder motors.

On the stand of the Société Parisienne, 10, Avenue de la Grande Armée, are

to be found three of the well-known Victoria Combinations, which present no new features. A novelty, however, is the parcel delivery quadricycle, built on very similar lines to the carriage. The driver is placed in front, with an ordinary bicycle-steering handle-bar and all controlling levers before him. The goods are packed in a box behind, and the general arrangement is well thought out and designed. Cycles make up the rest of this company's exhibit.

Visitors to the automobile section who delight in seeing vehicles which have accomplished exceptional performances, should make a point of inspecting the Renault car upon which MM. Schrader and Oury made a business tour of 5,000 kilometres in France between April 18th and June 20th of this year. It is fitted with a 3 h.p. Aster motor, water-cooled, and in spite of its long journey presents a wonderfully healthy appearance.

A provincial firm which makes an excellent display, as far as displays go in a space so confined as that at Champ de Mars, is MM. Rochet and Schneider, Chemin Feuillat, Lyons, and whose Paris representative is M. Victor Mathieu, 22, Rue Taithout. Three vehicles are displayed, a couple of the type already so well known, and a third built on Mors-like lines, which give one the impression of great speed. Provided with two seats and a dickey behind, this racing carriage carries its 14 h.p. four-cylinder motor in front and its controlling levers at the driver's right hand. The two other vehicles are both four-seated, the one carrying two seats

THE SCHEELE ELECTRICAL WAGON (See opposite page.)

projecting in advance, while the other provides a seat facing the driver for a couple of passengers. Both these cars are fitted with 8 h.p. motors carried on the rear part of the frame. The makers claim that their vehicles are the only ones completely complying with the French police regulations, which is perfectly possible, for automobile constructors do not materially differ from their fellow countrymen, and only follow the laws and regulations of their native land as far as it suits them. As prices go in France these Rochet-Schneider cars are not dear, costing as they do £380.

M. Jules Tourey, 66, Rue de Sevres, Paris, exhibits a single car of the Delahaye type of vehicle. It is designed to carry four passengers, and is fitted with a two-cylinder motor developing 8 h.p. The weight complete is 800 kilogrammes, and one is at once struck by the attachment of the shielded pneumatic tires, known as the Ferré Hélène, to the front wheels. The rear wheels carry Michelins. A hood is attached to the rear seat, and the green leather upholstery is nicely finished. The price is £432. M. Jules Tourey also constructs a 3 h.p. voiturette weighing 240 kilogrammes. The size of this little vehicle is 1m. 800 in length, by 1m. 280 in width. A couple of speeds, 12 and 26 kilometres per hour, are provided, and the price is £154.

MM. Goujon Frères, 23, Rue Borghèse, Neuilly (Seine), show a car designed to carry four persons placed *vis-à-vis*. A single cylinder horizontal motor is carried on the rear part of the frame, and the transmission is effected by cog-gearing. Three forward and one reverse speeds are fitted, and the car complete weighs about 650 kilogrammes. This carriage gives me the impression to be lacking in wheel-base, and it is also too high.

A well-constructed frame secures a prominent place among the exhibits of the Compagnie Française des Cycles et Automobiles, 7, Rue Darboy, Paris. It is built up of drawn steel tubes, and a special feature is the use of expansible pulleys for the gradual gearing of the motor to the car. The motor is carried in the middle of the frame and develops 6 h.p. It is of the single cylinder horizontal type, and is water-cooled. Three forward speeds and a reverse are provided. The complete car, as built upon this frame, is also shown. It carries a seat for two persons in front, and a dickey is attached to the back. The driver finds all controlling levers carried upon the pillar of the steering wheel in front of him. One of the company's 6 h.p. single-cylinder motors also finds a place upon the stand, and the remainder of the exhibition is made up of cycles.

The single voiturette shown by MM. H. Brulé et Cie., 31, Rue Boinod, Paris, is a four-seated *vis-à-vis* car provided with a 6-h.p. engine attached to the rear part of the frame. This motor is of the horizontal two-cylinder type, and the cranks are angled at 180 deg. Electric ignition is employed, and a special carburettor is conveniently placed for the driver to vary the explosive mixture. A speciality of MM. Brulé is the large 20 h.p. omnibus, of which, however, lack of space prevents the exhibition. The motor employed consists of two ordinary and one expansion cylinders, the latter being placed between the two others. Four speeds and reverse gear are provided, the drive being made through the medium of a friction clutch. The passengers are carried in the interior of the vehicle.

Among other exhibitors of small cars and motor-cycles I may quote the following names, the exhibits of whom, although excellent in themselves, present no features calling for special attention. In the majority of instances the de Dion motor is employed to supply the motive power, and the makers have devoted all their attention to the question of transmitting its power in the most effective and economical manner. These firms are:—M. P. Sage, 57, rue Emerian, Paris; La Société Phébus, 30, Avenue de la Grande Armée, Paris; MM. E. Chenard and H. Walcker, 7, rue de Normandie, Asnières (Seine); Agence Industrielle d'Automobile and G. Fouillaron, both of 54, Avenue de Villiers, Levallois (Seine); A. Cohendet, 166, quai Jemnapes, Paris; MM. Marot, Gardon et Cie., 37, rue Brunel, Paris, and La Société Française, Marque Diamant, 11, rue Brunel, Paris. La Maison Parisienne, 71, Avenue de la Grande Armée, and La Société Française d'Automobiles, 41, Quai de Suresnes, Suresnes (Seine), exhibit Benz and Gaillardet motors respectively.

The exhibition at Champ de Mars shows one nothing strikingly

new with the single exception of the Ader car constructed by La Société Industrielle des Téléphones, a description of which was given on page 392 of this journal. In this respect the show but resembles its immediate predecessors, for neither at the Salon du Cycle held in December last, nor at the Automobile Club's exhibition of June, 1899, was there any novelty which could command serious attention. It is the old and well-known types of motors which continue to hold sway—modified and improved, of course, but still motors of the types whose names they bear. The revolutionising engine has not yet appeared upon the scene, and would appear to be as far off as ever. The majority of new motors which do appear usually follow closely upon the lines of one or other of the recognised types, and, generally speaking, the most striking difference is the elimination of the older engine's good qualities from the new design. The old-established firms, who have already got a good motor and car, effect numbers of minor improvements, which, although small in themselves, are of great importance in building up a harmonious whole. To anyone who has had an intimate acquaintance with one or other of the leading types of automobiles for any considerable length of time, it is of immense interest to compare the present-day vehicle with that of former times. One recollects the troubles experienced with such and such a part, and an inspection of the modern car shows the little modification or addition which entirely overcomes the difficulty. So simple in itself is the change, and yet so effective. And there are dozens of these alterations which the keen automobilist notes. Then, too, there are the modifications of design, both of frame and of body, which do so much to increase the beauty of the vehicle and the security and comfort of the passengers. All this is to be seen at Champ de Mars, but of real novelties there is an absolute dearth. And now to Vincennes.

A PROSPEROUS undertaker in Florida talks of adding a motor hearse and carriages to his business requisites.

A NEW company has just been formed at Levallois-Perret, Paris, with a capital of £8,800, to be known as L'Equipage Electrique (Société de Location de Voitures Electriques).

MESSRS. HEWETSONS, LIMITED, of Dean Street, Soho, have now arranged to fit a third speed, when desired, to all their cars. The charge to fit the Crypto to old cars, we understand, is fifteen pounds.

SEVERAL motorists were returning to town along the St. Albans road on Sunday. One of our staff cycling that way passed a merry party in a large Benz dog cart, Mr. Cappellen on a motor-tricycle, and a couple of wayfarers on a De Dion voiturette.

PROBATE of the will of Mr. William Wright, of Saxelby Park, Leicester, and of Wollaton, Nottingham, J.P., a director of the Daimler Motor Company, Ltd., who died on the 14th May last, aged 61 years, has been granted to his widow, Mrs. Mary Jane Wright, and his son, C. W. Wright, of Edwalton, and W. D. G. Brown, of Kenilworth, Warwick. The late Mr. William Wright's estate has been valued at £222,974 17s. 7d. gross, including personality of the net value of £187,004 2s. 7d.

AUTOMOBILING has become so popular in Westchester County, of the State of New York, U.S.A., that a number of wealthy men have decided to organise a club which will be composed of automobilists in New York, Westchester and Connecticut. A meeting to make preliminary arrangements was held recently. The name of the club will not be decided upon until the next meeting, when officers will be elected. It was stated that one of the principal purposes of the new club will be to provide supply stations along the Albany post road, Boston post road, the new macadamised boulevards now being constructed through The Bronx, the Hudson River valleys and other cross country roads leading to the Ardsley Casino, Westchester County Club and Knollwood County Club. At these stations petrol and other material will be kept for petrol and steam cars, and arrangements will also be made for charging electric vehicles.

CORRESPONDENCE.

A MOTOR-CAR DRIVING SCHOOL.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I believe it would greatly further the enthusiasm that is growing in the public if enterprising manufacturers would combine to run a school where intending purchasers could go through a course of instruction similar to horse riding schools, and where a liberal display of up-to-date motor-cars could always be seen and tried.

A similar place to Tattersall's or Baker Street Bazaar would, I believe, be a great financial success. The now all prevalent hesitation regarding purchasing would then be speedily removed and confidence established. I shall be glad to hear what your readers think of the suggestion.

Yours truly,

DANDO HARPER.

18, Tufnell Park Road, London, N.
September 3rd, 1900.

THE ENGLISH MOTOR CLUB'S RUN.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—With regard to the English Motor Club's run to Luton and Bedford on Saturday, announced in the *Motor-Car Journal* of even date, will you inform me, through your columns (as the matter is of interest to others as well as the writer), the place and time of starting, as the notice appears to be incomplete without these particulars.

Yours truly,
W. G.

St. John's Wood, N.W., September 1st, 1900.

[Owing to the traffic out of London, and the fact that the participants in the meet will have variously powered cars, it has been thought advisable that the rendezvous should be beyond the metropolis. Those who go will, therefore, make their way to Luton by whatever route they prefer, reaching Mr. Hart's house in the Windmill Road, Luton, from whence the organised run to Bedford will commence, between 4 and 5 p.m.—Ed., *M. C. J.*]

MOTOR-VEHICLES AT BOGNOR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have been staying a few days at this breezy little town of Bognor. It is growing rapidly in favour as a health resort, and motor-cars are not altogether unknown here. Several of the residents in the neighbourhood own cars, and during the past few days two "quads" have been seen in the town.

During the summer months there should be a good opening here for a few public service wagonettes. The roads are level with good service, and a number of very interesting excursions can be made, which would doubtless be appreciated by the visitors as a welcome change from the monotony of pier and beach.

Hoping some of your business readers will think over my suggestion with a view to something being done another season,

Yours truly,

A VISITOR.

Bognor, September 5th, 1900.

FOUR electric carriages have begun regular trips through Central Park, New York, to Riverside Drive, and up the drive to Claremont. The vehicles carry twelve passengers and make the round trip in an hour.

The Automobile Rapid Delivery Company has been organised in Detroit, U.S.A., with a capital of £5,000. It is the intention of the company to carry on a parcel delivery system at first, but a passenger service will be established later on. Six cars have been purchased, and an electric vehicle, with a capacity of nine passengers, for tally-ho rides, will also be put into service shortly.

MESSRS. SCHLESINGER AND MAYER, of Chicago, have put in service a number of electric omnibuses between their store in State and Madison Streets and the Chicago and North-Western Railway dépôt. Three 'buses are already running, and seven more will be put on as soon as they are ready. This is the first service of the kind in Chicago, the vehicles belonging to the Illinois Electric Vehicle Transportation Company.

THE "S.S." MOTOR-CAR.

THE accompanying illustration shows the frame of the new car which is being put on the market by the S.S. Motor Co., of 59, Holborn Viaduct, London, E.C. The motive power is provided by a 5½-h.p. single-cylinder horizontal engine, fitted with electric ignition, using the De Dion plug; the cylinder is water cooled, the circulation being maintained by a centrifugal pump actuated by friction on the fly-wheel of the motor. The valves are of relatively large size, as is also, it will be noticed, the exhaust box or silencer, which is located at the rear of the frame. The carburettor is of the Le Blon jet type. As regards the transmission, three speeds forward—six, twelve, and twenty miles per hour—and a reverse motion are available. From the motor shaft the power is transmitted to a countershaft by spur wheels, the teeth of which are always in mesh. The pinions on the countershaft are rigidly keyed, while those on the engine shaft are free to revolve over separate friction

clutches. On the engine being started, the engine shaft and the clutches fixed thereto revolve inside the gear wheels, but upon any one clutch being expanded the gear wheel instantly becomes a part of the main shaft and the car is started. This, of course, brings all the gear wheels into motion, so that in changing speeds the operation is done with the gear wheels running in mesh. The same principle is applied in the reverse motion, but a chain is substituted for gearing. Wheel steering is fitted, while the engine is started by a handle at the side. The petrol tank has a capacity of a little over four gallons, said to be sufficient for an eighty miles run under adverse conditions. Eight gallons of water are carried. Ample brake power is provided, while the road-wheels are of the cycle type shod with pneumatic tires. The motor and transmission gear are mounted on a standard frame to which any type of carriage body can be fitted to seat either two, three, or four persons. The S.S. Co. inform us that every detail in the car has been thoroughly tested and subjected to long trial before being finally put on the market and they claim that with a full load of four persons the vehicle will easily ascend a gradient of one in six.

THE DULAIT-BARAS SPARKING PLUG.

THE accompanying illustration shows a new sparking plug which has lately been devised by two French engineers, Messrs. Dulait and Baras. It is composed of a tube of porcelain or other heat-resisting and insulating material, having a shoulder C, which, by the threaded collar K, is forced to a gas-tight joint in the side of the valve-box. Inside the tube is a stem T, having a head at one end and a screw-thread cut on the other. Usually this stem is set in plaster or something similar, so that it and the tube form a solid piece. Then, when it is heated, it expands lengthwise more than the porcelain, and consequently detaches itself and causes a leak. If it is attempted to screw it tighter when hot, to stop the leak, it is under strain

when cold, and either stretches or breaks the porcelain. It is the purpose of this new plug, states *La France Automobile*, to obviate this difficulty; and to this end the head of the stem T has a copper washer u interposed between it and the end of the porcelain tube, forming a gas-tight joint. The stem is loose in the tube and is somewhat longer than the latter. Threaded on the end is a cap P, with a lock-nut X; and inside the cap a stiff helical spring is interposed in compression between the cap and the end of the tube. By this means the head of the stem is always drawn tightly against the end of the tube, and the spring can be adjusted by screwing the cap P up or down. A washer u' of amianthus, covered by a metallic washer, aids in maintaining the gas-tightness of the stem in the tube.

MR. CHARLES WALKER, a civil engineer, of South Elmsall, has been fined 7s. 6d. and 14s. 6d. costs, at the Rotherham West Riding Police Court for having had a motor without a light at Swinton on August 20th.

THE number of firms in the cycle trade in the London districts interesting themselves in the motor-car business is steadily increasing. Among the latest is Messrs. Donald and Company, of the Ravenscourt Works, 61, Goldhawk Road, Shepherd's Bush, who are not only keeping a stock of petroleum spirit, but are also stocking motor-car and cycle accessories.

HORSES AND MOTOR-CARS.

THE fact that so many automobilists of repute are horse-men of renown should have secured for those who motor some consideration on the part of the public. Those who drive motor-cars are not enemies of the horse, and those who are endeavouring to perfect vehicles for heavy traction are really the best friends of animals, for they are seeking to relieve him of many burdens and worries.

But one can hardly open a newspaper without seeing some accident or other attributed to our means of locomotion, while should a horse shy or be misled into an accident he is given only a short and mild-mannered paragraph. This has several times been referred to in these columns, but it cannot be too often pointed out that many motor-car accidents are not motor-car accidents at all. They are caused by the horse and by the horse alone. It is all very well to say that motor-cars are such peculiar fantastic contrivances that any ordinary quadruped is frightened, but the same remark applies, with lengthened extent, to electric tramcars. At Southport, the other day, a pony which had long been accustomed to the electric cars that ply in that town shied at the light on one of them. Although the driver pulled up as quickly as possible the pony was knocked on the head and killed. Would it have been fair to ascribe that casualty to the electric car?

The truth is that accidents that happen within the range of the motor-car are due to one of two causes—excitable horses and nervous drivers. The latter cause, perhaps, more accidents than the former. They hear the "teuf, teuf" of the motor-car in the distance and prepare to get nervous; they fancy it is coming their way and rein up their horse, nearly dragging him into the nearest ditch. The advent of the car thus heralded to the intelligent quadruped, small wonder is it that when the mechanical vehicle does come along the horse rears and starts with all the energy of a ballet dancer playing for an encore. And if in the midst of all these gyrations the driver is thrown into the road the motor-car is blamed—though probably it is in the next street by the time such event occurs.

This is the age of societies and organisations. Let us have an association to teach ordinary courage and a little pluck to some of the nervous people who frighten the horses they drive.

Humanity generally will welcome the universal adoption of the motor-car, giving a means of locomotion a reliability that does not obtain in the case of horses. They have their moods and tempers; heat and storms affect their health, but the motor-car is always ready for service, and if sometimes it does turn a somersault or a tire gives way such incidents only give zest to the sport. It is the love of adventure, the chance of righting one's vehicle after a little upset, and such-like things, that have made sportsmen take to motoring as they have done.

Seriously, it must be confessed that the majority of the accidents that have taken place when motor-cars have been in the proximity of horses have been due to the careless disregard of ordinary disciplinary measures. If, instead of turning horses up side lanes or getting down and leading them past motor-vehicles the drivers would boldly drive them by, the difficulty would soon be got over and much worry and annoyance saved. That is the only satisfactory way of training horses. To set a horse in the centre of half-a-dozen throbbing automobiles letting him imagine that a score of iron animals are in pain is not indicative of much regard for the horse's intelligence. He must meet the automobile on the road, treat it as he would a cable tramcar, a traction engine, or a road-sweeper, and then little fear need be felt.

Horse owners must recognise that the automobile is going forward, and provincial journalists may be equally well assured of the fact. The days of ridicule are passing away; the strength of the once existing prejudices is waning, and the sooner everyone recognises that the horse and his driver are often to blame, and not the motor-car, when accidents take place the more accurate will be the character of public information.

"WHYBROW."

HERE AND THERE.

BY LOLLIIUS.

LITTLE is doing at the Automobile Club, most of the members being away on their holidays. They will soon be returning, however, for the dinner at the Trocadero, when the prizes in connection with the 1,000 Miles Trial will be awarded. At present these are on view in Whitehall Court, and a capital display they make.

LORD CARNARVON'S delight in motoring is well known, as the residents of Newbury and other Berkshire towns will tell you. Apparently he intends to discard ordinary railway travel, for it is reported that he will go by road instead of by rail to all the principal race meetings. In this way his lordship will secure a wider view of the country than is afforded from the train—an advantage that can only be realised by those who have had experience of both means of getting about. In the train your outlook is woefully circumscribed; from the motor-car all the surrounding country is opened out as in a book.

I HAVE just been chatting with the rector of a country village about two and a-half miles from Huntingdon—a quiet old country town in which, I believe, Mr. D. Murkett is the only man ready to look after the wants of automobilists. Dissatisfied with the ordinary and rather uncertain horse-drawn service to and from his place, he wanted something better and tried an ordinary tri-cycle—feeling rather too old to venture on a bicycle. Now he has grown tired of that, and is on the look-out for a small compact motor-vehicle to carry himself and luggage as well as a friend. But he does not want to have to employ a man to look after the machine; and yet is not, himself, inclined to engineering ways, and dreads having to approach a new study at his time of life.

AFTER telling him to try, I pointed to the great philosophers who had taken up a new language when beyond the age at which ordinary men were thinking of funeral arrangements, and generally urged him to recognise that the management of a motor-car might be easier than the study of theology. He sighed, and said it might, but was not converted. Still a good many motorists go Huntingdon way—and it may be that the next time I see the worthy rector he will be on a neat little motor-car. I hope he has not yet begun to subscribe to the *Motor-Car Journal*, as "The Trials of a Tyro" last week may cause him to reserve his money for awhile.

WITH Rudyard Kipling as a resident and Mr. S. F. Edge as a visitor the other week Rottingdean should have an interest for motorists. The author has a German Daimler which, when I saw it a few days ago, had a decidedly sombre appearance. There is no need to say anything about Mr. Edge's machine—now so well known. Although I was staying at Brighton at the time, I did not know he was so near until I read about his stay in the *Brighton Gazette*, which is edited by Mr. Towner, a really good friend of motorists, whose oratory was one of the notable features of the Motor-Car Club's dinner at the Hotel Metropole last November.

WHATEVER people may say of other places, I prefer the Thames Valley for motoring. Its sylvan delights are unlimited, and nothing can be more entrancing than to whizz along a dusty road for a few miles and then find oneself by the side of the river, with its cooling breezes. On its banks are some business connections reminding one of the ordinary world. The other day at Maidenhead I heard about the enterprise of a local firm interested in motor-cars and their ways, which had actually taken half a column of space in the local newspaper to advocate the claims of automobilism.

HEADING the advertisement as Motor Talk, the announcement was made that Messrs. A. W. Heybourn and Co. had run their motor-quadricle over 1,200 miles with "no accidents,

nothing but unqualified satisfaction." The running cost, oil, etc., was £3, or with depreciation of tires, minor renewals, etc., £6. Arguing that the cost of the keep of a horse and groom was anything from 30s. to 50s. a week, for which drives of about 120 miles could be enjoyed, Messrs. Heybourn and Co. show the advantages of the motor-quadricle by saying that that distance could thus be done in a day at a cost of from 5s. to 10s. for petrol. Such economical riding for two people should satisfy the greatest apostle of thrift in the pleasantest of pleasant boroughs by Father Thames.

FAMILIAR as automobiles are in Maidenhead, they are even better known in Windsor. Among recent converts to the motor-car in and around the Royal borough are Lord Edward Spencer Churchill, Mrs. Berens, and the Baroness Campbell, while the Duke of Newcastle was there last week on his Locomobile steam car, which has already carried him on many pleasant tours. His preference for the steam car is notable.

WHILE chronicling these items of social interest utility, may be given my diary by mention of an excellent place for the repair of vehicles, should difficulties occur in the neighbourhood.

This is the establishment of Messrs. J. Fullbrook and Co, at Slough, on the London and Bath road. Mr. Fullbrook is an enthusiastic motorist, and may be seen, in the accompanying illustration, aboard his car. He is putting parts in stock for replacement—a branch of trade in which good business is likely to be done in many places in the future.

I HEAR that Captain Langrishe intends to dispose—if he has not already done so—of his 8 h.p. Peugeot, and also his 2½ h.p. De Dion trike. Applying the principle that horses are valuable because of the races they have won, I would mention that both these machines enabled their owner to win contests at the Ranelagh and Sheen House Gymkhanas.

IRISH noblemen seem to be taking to automobilism with great enthusiasm, the latest to join the ranks being Lord Louth, of Louth Hall, Ardee. He purchased a motor-tricycle from the Dublin branch of the Cycle and Motor Company, and after about ten minutes' tuition, according to one of my Irish correspondents, went eighteen miles without assistance. Since then he has had many trips in the congested streets of Dublin and seems thoroughly enamoured of his new possession.

THE Electrical Vehicle Company of New York have sent us a copy of the new catalogue which they have recently issued. It is beautifully executed, with pen and ink sketches of their factory, famous pieces of architecture and landscape, combined with half-tone illustrations of the many types of Columbia vehicles built by the company, the details of each one being given below the engraving.

A COMPRESSED AIR MOTOR-WAGON.

UP to the present time the ideal motor for hauling heavy weights is still the steam engine, but lately a new competitor has been brought forward in the shape of a compressed air motor-wagon, of which an illustration is given herewith. It has been constructed by Messrs. Molas, Lamielle and Tessier, of Paris, and has recently attracted considerable attention by reason of the relative simplicity of arrangement of its manœuvring devices and the limited amount of space occupied by the motive apparatus.

In this vehicle the air-storage reservoirs employed consist of hammered steel tubes of 8-inch external diameter. The heating is done directly by petrol instead of by steam from a boiler, as in the Mekarski system, the manufacturers being of the opinion that, since a direct heating of the air permits it to be raised to a temperature much higher than that which could be obtained by means of heating by steam, they obtain also a greater increase of volume, and, consequently, of work that compensates for the heating during expansion obtained with the above-named system.

The stove, burners and petrol reservoir used for heating have here but a light weight as compared with the arrangement in which a boiler is employed. The air reservoirs are eleven in number and are distributed in two groups, one of six forming the "battery," and the other of five constituting the "reserve." The capacity of these groups is, respectively, 11 and 7.5 cubic feet,

FIG. 1. GENERAL VIEW OF WAGON.

or, altogether, 18.5 cubic feet. With a charging pressure of 4,290 lb. to the square inch, the weight of air stored up, at a temperature of 13 deg. C., is 1,100 by 2.7 by 638, equals 392,370 lb. Before its admission to the cylinders of the motor, the air passes into a steel worm of .28-inch internal diameter, of 14-inch thickness, and of a length of 19.7 feet, which raises its temperature to a figure that varies with the discharge of air and the intensity of the burners that heat the worm. The temperature may thus reach 150 deg. C. The air afterwards passes into an expander, manœuvred by the driver, which lowers its pressure by about from 11 lb. to 4 lb., according to the difficulties of the road, the load, and the speed. It is in this way that changes of speed are effected—by admitting the compressed air at higher or lower pressure into the cylinders through the valve, so that from 1 h.p. to 35 h.p. can be delivered at the driving axle, corresponding for a load of two tons, to a varying speed on the level of from one to ten kilometres ($\frac{5}{8}$ to $6\frac{1}{4}$ miles) an hour. This expansion of the air gives rise to a lowering of the temperature, in order to raise which the air thus expanded is made to pass into a second worm concentric with the first and heated by the same burners. When the air makes its exit from this second worm its temperature may be as high as 250 deg. It is claimed that this double heating is

capable of more than doubling the volume, and, consequently, the work of the air stored up. This air is then admitted to the cylinders through an expansion distribution with a special change of speed. The admission takes place upon only one of the faces of each piston, and the motor is thus a single acting one. But the cylinders are four in number, and cast in pairs, and the connecting rods (jointed directly to the pistons) actuate the same shaft, the cranks of which are set at an angle of 180 deg. per group, and at 90 deg. from one group to the other. The motor thus has the same power as a two-cylinder double-acting engine. The arrangement, it is claimed, offers numerous advantages, and permits especially of suppressing the shocks at the joints of the connecting rods that occur in double-acting engines at the time of the change of direction of the piston; of doing away with piston-rod stuffing-boxes, which it is often difficult to keep tight, and which absorb a certain amount of work in friction; of removing and putting in place a connecting rod and its piston without having to dismount a cylinder bottom.

The distribution is effected by means of cams and valves. The opening of the latter takes place very rapidly. Their closing, on the contrary, occurs gradually, and is hastened or retarded through the shifting of the reversing lever, according to the admission that is desired. The minimum admission employed is 10 per cent., but this may be increased to 60 per cent. for starting. The exhaust and the compression are fixed, and have a duration of 20 per cent. of the stroke of the pistons. There is no special cut-off of fluid between the expander and the cylinder admission valves. These latter open wide for all admissions between 10 and 60 per cent. of the forward and backward running of the engine.

The burners, which are three in number, are arranged beneath the worms in an iron-plate jacket 10.75 in. in diameter and 12 in. in height, surmounted by a chimney which conducts the gases of combustion to the top of the roof of the vehicle. The burners are supplied by a petrol reservoir of a capacity of about five gallons, in which an air pressure of from 45 to 70 lbs. to the square inch is created. The pipe that leads the petrol to the burners may be partially closed by a screw plug. Through such arrangements it is possible for the driver of the wagon to proportion the intensity of the heating to the output of air, so as to obtain a temperature that is always sensibly the same. The quantity of petrol consumed by the burners is said to be about 15 oz. per hour of running.

The motor rests upon the floor of the carriage, beneath the seat occupied by the driver, who can thus examine it while it is running. Its rotary velocity for a speed of five miles an hour made by the vehicle is 200 revolutions per minute. The transmission is effected by means of chains which connect two sprockets, keyed at the extremities of the driving-shaft, with two toothed wheels of six times larger diameter fixed through bolts to the spokes of the hind wheels. The power of the motor upon the crank-shaft is 20 horse at a velocity of 300 revolutions, and at a pressure of 285 lb.

The differential consists of two friction cones fixed near the extremities of the driving-shaft and actuated by the steering apparatus, Figs. 2 and 3. The control of these cones is such that, in a turning about, the adhesion of the one that is situated at the side of the internal wheel diminishes in such a way as to permit of a certain amount of sliding of the cone in its socket, and, consequently, of a retardation in the revolution of the corresponding wheel; while the adhesion of the cone situated at the side of the wheel that is to traverse the wide radius increases, so that no sliding in its socket can occur, despite the greater resistance of the wheel that is moving ahead. The pivoting can thus be effected upon a driving wheel that is rendered absolutely immovable, from the view-point of revolution, and, consequently, in a circle having as a radius the distance of such wheel from the opposite wheel of the front axle, and that, too, in running forward as well as backward.

The steering is done by means of a hand wheel keyed upon the axis of an endless screw, which gears with a toothed wheel keyed upon the shaft of the reversing gearing situated beneath the vehicle. An indicator placed before the driver exactly reproduces the changes in direction of the axis of the

vehicle's path, and thus permits him to keep in a straight line. The intermediate screw lengthens the manœuvring, but renders it sure, stable and gentle. Such an arrangement, however, offers advantages only for heavy vehicles designed for running always at a low speed. Finally, it may be mentioned that the accumulators are placed longitudinally under the floor of the vehicle in two superposed rows, and are connected by easily accessible couplings placed in the rear. Movable panels permit of an inspection and of a tightening of the joints and couplings.

The whole of the compressed air is practically available for driving purposes, and the holders can be recharged during loading up, in the dinner hour, or after the day's work during cleaning down. With a compressing plant of 5 h.p. (gas engine) costing £300, the production of 100 kilogrammes of compressed air is said to cost 8s., and every succeeding 100 kilogrammes, if the plant is worked continuously, 4s. Four hundred pounds of com-

FIGS. 2 AND 3. ELEVATION AND PLAN OF DIFFERENTIAL GEAR.

pressed air will, it is claimed, transport 20 tons of goods for 30 miles on one of these vans. The rate of transport per ton-kilometre amounts to a little over 2½d. for 50 kilometres, and is under 2d. for 100. One of these vehicles will, it is claimed, do the work of six horses and two vans, carrying 1½ tons each and with a radius of delivery of 25 kilometres (15½ miles), the goods handled by which cost per ton-kilometre about 6½d. (10½d. per ton-mile).

A PHILADELPHIA undertaker is stated to have an automobile funeral wagon in successful use, and intends to add five more.

THE Painesville Automobile Company, organised some time ago at Painesville, Ohio, U.S.A., to operate an automobile 'bus line between that town and surrounding villages, is in the market for several vehicles of large passenger carrying capacity. Early last spring the company contracted with a New York concern for a sample vehicle which was to be delivered during June, but after repeated promises of delivery the vehicle seems farther from completion than at the start, with the result that the contract has been cancelled.

MOTOR-CARS ON THE CONTINENT.

(From Our Own Correspondent.)

At Brescia.

THURSDAY last witnessed the opening day of the Brescia meet, which has been so eagerly looked forward to by Italian automobilists. A well-organised exhibition of vehicles is being held in the splendid hall of Crocera Saint Lucas and short distance races are being decided daily. To-morrow a six kilometre event will be run off over a rectangular route from Bagnolo Mella to Saint Zeno Naviglio, and Monday will witness the most important race of the meeting. This will be decided over a route of 223 kilometres, from Brescia by way of Cremona, Mantua and Verona back to Brescia. Some £240 worth of prizes will be competed for during the meet, and all the crack Italian *chauffeurs* as well as several strangers will be seen racing.

A Racer Fined.

It will be remembered that in the Bordeaux-Périgueux-Bordeaux race of June 4th last, Antony, one of the hot favourites, did not finish, but that he fully intended to be in at the death was conclusively proved some few days ago at the Angoulême police court, where the local justice of the peace condemned him to pay a fine of five francs for refusing to stop when ordered to by the town police. A like offence in Paris would have cost M. Debray, for such is Antony's real name, probably ten times the amount of this fine and a few days of imprisonment besides, so he cannot complain as to the severity of the sentence. But even in Paris the sentences passed upon offending *chauffeurs* are moderating, as, indeed, is the whole campaign against the automobile, and before long cases in the courts will be as rare as of yore.

Belgian Customs.

THE secretary of the Automobile Club of France informs members, in a recently issued circular letter, that they can now pass their motor-vehicles through the Belgian Customs without any other formality than the presentation of a sort of pass called a "triptyque." This measure has been brought about by the goodwill of the Belgian Minister of Finance and an understanding with the "A.C.B." The pass is procurable at the club-house, 6, Place de la Concorde, Paris, upon depositing a sum equal to 12 per cent. of the value of the car, which amount is refunded upon the return of the automobilist to France. Similar arrangements are in course of negotiation with other countries, and, although members of the English Automobile Club do not apparently indulge in automobile travelling on the Continent to any extent, it is to be hoped that the Club will secure the same privileges, for later on the desire for extended tours will undoubtedly increase, and then the facility of entering a foreign country under such easy conditions will be a perfect boon. A circular tour in Europe is at present a trial and tribulation so far as the formalities of the several Customs are concerned, and many people are undoubtedly deterred from making such trips by this reason.

Military Motor-Cars in Germany.

ON the day that the Count of Waldersee took leave of the Emperor of Germany at Cassel, prior to his departure for China, an elegant four-seated motor-car was inspected by the Emperor. The vehicle is intended for the use of the officers of the Magdeburg garrison, and is to be employed in conveying them to and from the manœuvring grounds at Libourg.

THE local authorities at Rochester, N.Y., are considering a speed ordinance similar to that proposed in Syracuse. The speed for all motor-vehicles is limited to eight miles an hour, which is reduced to six within a radius of one-half mile from the city's centre.

ELECTRIC IGNITION TROUBLES.

MOTOR-CYCLES and motor-cars frequently fall into the hands of those who are unacquainted with electrical matters, and to such persons the ignition frequently gives serious trouble, serious because the novice is at a loss to remedy the same. It is, to say the least, quite annoying for the automobilist who has just paid a substantial consideration to some exultant farmer for horse-hauling his vehicle to the shop of one who knows, to have that worthy run his fingers over the vehicle, tighten a screw, and then to start off as though nothing had happened. In the course of an article in the *New York Automobile*, a writer states that he has seen this situation materialise more than once, and therefore ventures to offer the following rules, which, though highly elementary, are invaluable to those who do not know them. A sparking device fails through one of three causes: Open circuit, short circuit, or dead battery. An open circuit is a discontinuity in the electric circuit. It may be due to (a) a broken wire; (b) a loose screw; (c) a bad joint; all joints should be tight metal to metal contacts; (d) contact on the engine failing to touch. Broken wires are quite deceptive at times. They may appear continuous while being merely held together by the outside wrapping. Similarly a defective joint will not disclose its nature till stripped and examined. A well soldered joint removes much uncertainty. Loose screws are the most frequent troubles, as the jar of the vehicle invites them. The wires connecting the batteries together are just as important as those leading from the cells.

The first thing to do when the ignition fails to work properly is to see that all the screws are tight. Next examine all the moving contacts and make sure that they are operative. After these are found secure broken wires or bad joints may be sought. A short circuit is a spurious path for the current other than through the engine contacts. It deflects so much current from them that they fail to operate. For instance, suppose the two wires leading to the contacts become bared and crossed before they arrive there. It is unlikely in that case that any current worth mentioning would appear at the contacts. A similar result would obtain if both wires were bared and pressed against the ironwork of the frame. In many vehicles one wire is permanently attached to the frame, and the operation of the device depends solely on the insulation of the other. To avoid short circuits keep the wires insulated from the frame and from each other. In hunting short circuits suspect every spot where the insulation appears defective. Dead batteries obviously cannot give current for sparking purposes. Short circuits and long usage are mainly responsible for dead cells.

THE newly-formed Pennsylvania Automobile Club held a successful run recently from Philadelphia to Willow Grove via Chestnut Hill.

A NEW two-seated electric car has lately been constructed by Mr. D. L. Davis, superintendent of the Salem Electric Light Company of Salem, O., U.S.A. Its trial trip has been made, and we are told it proved most satisfactory in its workings. In the construction some new ideas have been adopted. The car has a wheel base of 54 inches, and, owing to its different construction from other vehicles, its body is small, and lower than customary, and the batteries of 40 cells are below the axle line. The wheels are of the cycle type, shod with pneumatic tires. Two springs only are used—one on either side of the body and directly beneath the passengers. The power is supplied by two 1 h.p. electric motors, which are connected with the front wheels, working independently of each other. The vehicle is also steered by the front wheels, which swing on pins close to the inside of the wheels, carrying the motors back and forth with them, the connection being made with brass contact plates which allow for the swing of the wheels. The framework is of tubing, which is carried from the body up to the top of the front axle, and through this tubing is carried the wiring from the batteries to the motors. The brake is stationary, the wheels being drawn up to the shoe when the brake is applied. The reversing lever also applies the brake.

SOME ACTUAL WORKING COSTS OF MOTORS FOR STREET WATERING AND DUST REMOVAL.*

By E. SHRAPNELL SMITH.

AT the Birmingham Congress of the Sanitary Institute, two years ago, I read a paper entitled "Some Sanitary and Allied Advantages Attending the Introduction and Use of Motor-Vehicles," and at your own Congress at Glasgow last year I read a second entitled "The Application of Mechanical Power to Street Cleansing." On each of these occasions I was rewarded by a unanimous resolution in favour of the adoption of self-propelled vehicles in place of animal haulage, and one may, perhaps, be excused for inquiring as to the *raison d'être* of a third paper. Two replies suggest themselves in explanation. The first is that, the motor-vehicle industry being a new one, fresh data will probably have accumulated in an interval of twelve months. The second is that a few more facts will not fail to have their effect in deciding authorities who are at present in doubt. These contentions are certainly sound, for the experiences of the last twelve months are most important and in close agreement with previous estimates; in fact, it would have been a source of subsequent regret to me had I neglected this opportunity of speaking for the movement whose good I have at heart. And here I may venture to remind you that I have no connection with any firm manufacturing motors, my position as hon. secretary of the L.S.P.T.A. being contingent upon perfect freedom. Consequently, I feel that you will have confidence in my views and in the absence of bias or prejudice from any opinions I may express.

I shall refer at once to the Chiswick results. The Surveyor, Mr. Arthur Ramsden, recently gave the automobile world a shock by publishing a report, in the form of a summary, which I give *in extenso* :—

SUTTON COURT,

CHISWICK, 15th May, 1900.

COMPARATIVE STATEMENT OF COST OF COLLECTION OF DUST BY STEAM MOTOR VANS, HORSE VANS, AND CARTS, FROM 5TH MAY, 1899, TO 3RD MAY, 1900.

STEAM MOTOR VANS.			
Weight collected :		Motor drivers' wages ...	£147 10 0
Tons. Cwts. Qrs.		Cost of collection—	
2,261 12 0		Labour at 1s. 6d. per ton ...	169 12 5
		Oils, &c. ...	33 2 8
		Coal ...	88 13 5
		Repairs ...	190 10 6
		T. Bills ...	15 7 7
		Interest and repayment of loan ...	82 11 9
			£727 8 4

Equal to an average of 6.43 shillings per ton.
Total amount expended on repairs to steam vans since June, 1897, when purchased, is £324 8s. 9d. Taking this year's proportion at £110, the total cost of repairs in above statement would be reduced by £80 10s. 6d., which is equal to a less cost per ton of ... 71 shillings

5.72 "

HORSE VANS.			
Weight collected :		Cost of collection—	
Tons. Cwts. Qrs.		Labour at 1s. 6d. per ton ...	£156 7 4
2,084 17 3		Hire of horses and men, 568 days at 8s. ...	227 4 0
		Interest and repayment on loan ...	14 5 0
		Allow for repairs, painting, etc. ...	15 0 0
			£412 16 4

Equal to an average of 3.96 shillings per ton.

HORSES AND CARTS.			
Weight collected :		Cost of collection—	
Tons. Cwts. Qrs.		Labour at 1s. 6d. per ton ...	£146 5 9
1,950 9 2		Hire of horses and men, 593 days at 8s. 6d. ...	252 0 6
		Allow for repairs, painting, etc. ...	10 0 0
			£408 6 3

Equal to an average of 4.18 shillings per ton.

* From a paper read at the Annual Meeting of the Association of Cleansing Superintendents of Great Britain at Salford, on the 30th ult.

These data look very bad for the motor, but they are no criterion of the results that have been obtained since the two motors were purchased in June, 1897. Further, they are incomplete, even for the period embraced, without an explanatory statement respecting local circumstances. Mr. Ramsden, who is a firm believer in the economy of mechanical cleansing, has supplied me with facts which place an entirely different complexion upon what, at first sight, admits of nothing but a construction adverse to the motor. I have collated these facts in tabular form :—

Year Ending March 31st.	Estimated.		Cost of Dusting.
	Population.	Houses.	
1895	23,982	4,796	£1,400
1896	24,582	4,916	£1,654
1897	25,000	5,000	£1,545
1898	25,972	5,195	£1,253
1899	26,772	5,354	£1,410
1900	27,772	5,554	£1,809

The first motor began work on August 14th, and the second on November 6th, 1897. The horse contractors' tender for the year ending March, 31st, 1898, was £1,900, whereas the actual expenditure was only £1,253. Thus the motors, for which £350 each was paid, effected a saving of nearly their prime cost in the first six months of their employment. At the end of this period, the Surveyor referred to the motors as follows in his annual report:—"I am very pleased to say that they have in every respect answered what I foreshadowed in my last year's report. Owing to the rapid growth of the parish, coupled with a large decrease in the number of empty houses, the amount of dust to be removed has increased considerably, and I should strongly recommend the purchase of another steam tip-wagon, which could be used as a slop cart, dust cart, or water cart." Now, since the horse contractors' tender for the year ending March 31st, 1898, was £1,900, it is pretty certain that it would not have been reduced for subsequent years, when provender and other stores had advanced in cost. Three years' work at this rate would have amounted to £5,700, whilst the recorded cost has been £4,472.

Will anybody quarrel with a departure that has reduced the cost of dusting by £1,228 in thirty months, notwithstanding a mean annual growth of the district by 185 houses? But this does not dispose of the high costs of the motors during the last year. I have made careful enquiry into the falling off, and have come to the conclusion that the motors are now worked at not more than about half their capacity even for the single shift during which they are out. The mileage is only seven per day, and not more than three loads are collected. Further, there appears to be steady obstruction by horse interests in the Council, whereby orders for repairs are delayed, and the motors obliged to spend days, and even weeks, in enforced idleness. In addition, the motor performs services which are not included in the statement of dust collection. These are, particularly carrying five to six-ton loads of slop on Sundays and on other occasions, a matter which will soon add say 100 tons to the weight stated in the published results. Again, until a few months ago the motors had to run over about 300 yards of an uneven sleeper track leading to the tip, which seriously strained the connections and mechanism whilst it saved the Council 2s. 6d. per ton for barging. Lastly, the two motors are of the earliest type, now relatively obsolete, and I cannot comprehend the parsimony of the Chiswick U.D.C. in not getting rid of them and purchasing two modern ones, such as that now at work for the Strand Board of Works, with which I deal later.

I had hoped to refer at some length to the costs of working at Liverpool and Chelsea. Mr. John A. Brodie, the City Engineer of Liverpool, has been using a vehicle, built by the Lancashire Steam Motor Company, Ltd., Leyland, for eighteen months, but has so far given it work upon the conveyance of

four-ton loads of tramway material and other heavy stores. The working has proved satisfactory and highly economical, but has no reference to watering or dusting. Mr. T. W. E. Higgins, Surveyor to the Chelsea Vestry, has had a Thornycroft motor at work for six months. This was purchased from the makers at a reduced figure, on account of its not being a new vehicle, and was fitted with watering and dusting bodies, but Mr. Higgins, like Mr. Brodie, has found the motor so useful for carting four-ton loads of stores, flagging, cement, etc., that, whilst it has at times done the work of four vans in watering the King's Road, Chelsea, no dusting has been done. Partly in consequence of this splitting up of the work, and for other reasons, Mr. Higgins informs me that he is not publishing any figures at present. The Chelsea Vestry have also ordered two motors from the Lancashire Steam Motor Company, one of which was delivered two weeks ago, whilst the other is nearly ready for delivery.

I am indebted to Mr. Arthur Ventris, Engineer and Surveyor to the Strand Board of Works, for detailed information upon the working of the Board's Thornycroft motor between February 5th and August 4th of this year. The records are divided into three periods, viz. :—

First.—Motor on hire from February 5th to March 31st, say eight weeks, used in dust collection only.

The motor was then sent to the makers' works, where it remained for the month of April for overhaul, painting, and the construction of new tipping and watering bodies. It was then purchased complete, with two bodies, for £750.

Second.—Motor working from May 1st to June 18th, say seven weeks; used in dust collection only.

Third.—Motor working from June 19th to August 4th, say seven weeks; used in dust collection between 6 a.m. and 11 a.m., in street watering between 11 a.m. and 6 p.m., and in flooding the streets (preparatory to the flushing by fire hose) between 11 p.m. and 5 a.m.

The performance obtained has been as follows :—

Period.	Work.	Weight of Dust Collected and Tipped.		Watering.		Flooding.	
		Total.	Weekly Average	Days.	Loads.	Days.	Loads.
First	{Dusting—6 a.m. to 6 p.m.}	252	31.5	—	—	—	—
Second	{Ditto.	363	52.0	—	—	—	—
Third	{Dusting, Water- ing, Flooding, Two Shifts.}	189	27.0	25	225	37	777

It will be observed that better work resulted during the second period than was the case when the motor was on trial. This is due partly to increased experience in handling, and partly to the regular use of a trailing dust-van on one run per day. But the third period is the most interesting, and I pride myself that Mr. Ventris has followed the suggestion contained in my paper read at Glasgow last year. The motor is at work day and night, though the fires are drawn at 6 p.m. and re-lighted at 11 p.m., the duties being divided between two drivers. At present, it is found necessary to have an assistant with the watering-tank body in the day time when the traffic is heavy, to work the levers controlling the water delivery, but Mr. Ventris thinks this extra man may be superfluous if a van is fitted with foot levers. The water tank has a capacity of 700 gallons.

Passing now to a comparison with horse work, Mr. Ventris points out that he has discontinued the work of three single dust carts, horses and drivers, and finds that the work is done better and more speedily. The house dust, which is collected for the most part between 6 a.m. and 10 a.m., is very light, and the weight does not convey a correct idea of the labour in collection. I may say that the yearly average for the Strand district, exclusive of street and market sweepings, is 1,265 tons per mile of street per annum, whilst the bulk is 4,216 cubic

yards. This gives an average weight of only 6wt. per cubic yard. The average morning run of the motor in this collecting is sixteen miles. In addition to this replacement, Mr. Ventris has discontinued the use of two water-vans, horses and drivers, that were previously engaged in flooding the streets prior to the flushing by fire-hose at night.

The reduction of cost thus obtained is, per annum :—

Hire of five horses and harness (feeding and stabling done by contractors), at £65 per horse	£325	0	0
Dust vans are owned by Board, and used for other purposes	0	0	0
Hire of two water vans, at £16	32	0	0
Three drivers of dust vans, at £71 10s.	214	10	0
Two drivers of water vans, at £84 10s.	169	0	0
Oiling and repairing three dust vans, at £8	24	0	0
Third-party insurance on five vans	7	10	0

Total reduction in cost per annum ... £772 0 0

The expenditure in respect of the motor has been—

First Period.—Hire for eight weeks at £7 10s. per week, for day work only, inclusive of all charges.

Second and Third Periods.—These aggregate a clear three months. The appended table, supplied by Mr. Ventris, is in proportion, and may be relied upon as being the outcome of experience.

ESTIMATED ANNUAL EXPENDITURE.

Interest and return of capital, spread over ten years, say	£82	6	0
Fuel—36 cwt. per week, at 32s. per ton, say	150	0	0
Wages—Two drivers at 37s. per week	192	8	0
Attendant to work levers of water van on day shift, at 25s.	65	0	0
Repairs—Thornycroft's guarantee	75	0	0
Lubrication and waste	20	0	0
Boiler insurance on £2,000	3	4	0
Third-party insurance	10	10	0

Total cost per annum ... £598 8 0

The saving per annum is, therefore, £173 12s. per motor, when the capabilities of the mechanical vehicles are properly utilised, and the operations organised upon such excellent lines as one finds in the Strand district. Steam is the only power within the range of practical politics, and solid fuel, i.e., coke or coal, is more economical than oil fuel. Prospective users must not be afraid of the high prime cost, for motors give results commensurate with the initial outlay.

I have every confidence in urging the adoption of motors for use in operations similar to those so admirably carried on in the Strand district. The warnings I would give are :—

(a) Concentrate sufficient dustmen upon the motor to permit of its large capacity being taken advantage of.

(b) Arrange for all repairs to be made promptly, and for periodic tightening of the wheels in a hydraulic tyre-setting machine.

(c) Work the motor two shifts per day.

A STAR car is owned by a resident in Minehead and is in daily use.

SAN FRANCISCO had an automobile division in the Fourth of July parade. This is the first parade the Californians have been treated to and the display of motor-cars was considered quite creditable.

A TWELVE-SEATED wagonette has lately been built by the Electric Vehicle Company, New York, for use by public service companies in New York, Boston, and Chicago. The motive power is electricity, and the vehicle has a capacity of twenty-five miles on one charge of the battery at a maximum speed of ten miles an hour.

THE Chicago Automobile Club is the name finally fixed upon for the motor-vehicle organisation in Chicago. It is estimated that there are about fifty private parties owning or controlling automobiles in Chicago, and about half of these are charter members of the club. On the occasion of the first club run sixteen vehicles turned out. Meeting in front of the Auditorium Hotel on Michigan Boulevard, the members drove north to the Lake Shore Drive and Lincoln Park, and on to the Bismarck Garden, afterwards dining together in Chicago.

FURIOUS DRIVING CASES.

At Great Yarmouth Police Court, on Friday last week, Edwin Chiel of 15A, Baker-street, London, was summoned for furiously driving a motor-car.—Detective-Sergt. Moore said on Monday, about one o'clock, he was on the Drive, where he saw the defendant driving a four-wheel motor-vehicle in the direction of the Aquarium. He was going at the rate of 10 to 12 miles per hour. There was a large number of people about at the time. Upon being stopped, defendant said he thought he could drive 12 miles an hour. He had driven thousands of miles, and could pull up the car within two yards.—Defendant said the legal limit was twelve miles an hour, and he should not think of endangering the lives of his passengers.—The Clerk explained that under no circumstances could he drive more than 12 miles per hour, but the Local Government Board regulations further laid down that he could not drive at any speed greater than was reasonable and proper, so as not to endanger the life of any person.—Sergt. Mason corroborated Detective Moore's evidence. He considered that the defendant was driving at a dangerous rate. A few Sundays ago he cautioned the defendant, who was then driving a three-wheeled motor-vehicle at a terrific rate.—Defendant said he had never before been in trouble with the police. He had driven motors and cycles for years. With all motor-cycles the pedals were stationary, and they appeared to be travelling very rapidly. He had the machine under proper control, and could pull it up in its own length. He extended invitations to the magistrates or any officer of the court to take a seat in the vehicle, and see for themselves the power a skilful driver had over such machines.—Defendant was fined 20s., including costs.

At Bridlington Petty Sessions last week, O. Hey, Mannington, was fined £1 and costs for driving a motor-car through the streets on the 11th ult. at such a rate as to be dangerous to the public safety.—P.S. Richardson proved that the defendant was driving through the crowded main streets at a rate of from 12 to 15 miles an hour.—Defendant said he was not going more than six miles an hour.

THE STORAGE OF PETROLEUM.

At the Hove Petty Sessions on Monday, Frederick John Foulger, Church-road, cycle and motor agent, was summoned for keeping on his premises a larger quantity of petrol than three gallons without a licence, at Hove, on August 15th. Mr. R. Foulger, of the defendant firm, appeared, and pleaded guilty. George Presslie, an officer under the Petroleum Act, proved finding four ten-gallon drums of petrol in a room at the back of the defendant's shop on August 15th, and that he purchased samples of it. It was a dangerous oil, very volatile, and defendant had no licence. Mr. Foulger said the firm were under the impression that they did not require a licence for any quantity under sixty gallons, and, on finding out their mistake, they at once applied for a licence. Witness produced a printed pamphlet bearing out his statement as to the sixty gallons, but it was pointed out that the advice that a licence was not required for a smaller quantity was contradicted in another part of the book. A fine of 20s. and costs was imposed.

CHARLES GARBUTT GODDARD, George-street, was summoned for a similar offence at Hove, on August 23rd. In this case the Inspector said the defendant had forty gallons on his premises. The previous day he received fifty-four gallons. It was a dangerous oil. Defendant admitted having the oil on the premises, but pleaded ignorance of the law on the question of storage. He followed the book referred to in the last case, and thought he was perfectly safe. He spoke to the Inspector on the subject of a licence before he visited the premises. A fine of 20s. and costs was also inflicted in this case.

LEAVING A CAR UNATTENDED.

PERCY FRANK MADGE was summoned at the Ramsgate Police Court for being the driver of a carriage, and leaving the same for thirty minutes so as to obstruct the free passage, at Minster, on Sunday, August 12th. He pleaded "not guilty." Corporal Acton said he was on duty at High Street, Minster, when he saw the motor-car standing by the roadside. There were a number of vehicles drawn up on one side of the road, but the motor-car was on the other side. He asked the ostler of the inn, outside which the car was standing, if he knew to whom it belonged, and found that it was the defendant, who came out and asked if it was in the way, and drew attention to the other vehicles. In cross-examination witness said there was plenty of room for other vehicles to pass, but there was not room for a brake and a carriage to pass at one time. A Mr. Beerling, a brake proprietor of Margate, said at 4.30 or 4.35 p.m. on the 12th August he arrived with his brake at Minster. In consequence of the motor-car being in the way he could not unload without causing an obstruction, so he obtained permission to unload in Mr. Goulders' yard. Defendant said he did leave the motor-car on that side of the road, for he was afraid his engine might frighten some of the horses. He also thought if he took the car into the stables it might frighten the horses there, as even the sight of a motor would frighten some horses. He went into the tea gardens with his wife. After the magistrates had deliberated for some time in private the Chairman said: The Bench are not unanimous in their decision. They do not think there was proof of obstruction sufficient to convict, but they hope in future motor-cars will not be left in the road unattended. The summons was dismissed.

THE Motor-Car Journal.

VOL. II.]

LONDON, SATURDAY, SEPTEMBER 15, 1900.

[No. 80.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

THE Prince of Wales has evidently caught the automobile fever, and is determined to become acquainted with the various forms of motor-carriages. He has just been enjoying some delightful rides on a steam vehicle, and, according to some accounts, has been urging M. Serpollet, who drove, to the topmost speed. Reports of thirty miles an hour with the Prince aboard would probably cause consternation among the English constabulary. The vehicles on which the Prince was driven from Homburg to Langen-Swalbach and back (a distance of eighty miles) was a Serpollet steam car. On the following day His Royal Highness (who donned the goggles to avoid the inconvenience of the dusty road) went to Frankfurt, and has evidently been well satisfied with his adventure. Mr. Gardiner, who is associated with M. Serpollet in his undertaking, suggested the trips to the Prince, whose automobile education is advancing rapidly.

The Kaiser's Car.

A REPORT of the motor talk between the Emperor of Germany and the Prince of Wales should be interesting reading, for both are in the first flush of the happiness of possession. The Kaiser's car is from the Daimler Works at Cannstatt, and cost £1,800—if rumour speaks truly. It has been accommodated in one of the buildings attached to the Royal palace at Potsdam. The car has seating accommodation for four persons, weighs 32 cwt., and has a very high rate of speed. What will happen in Germany should the Emperor be seen going beyond the recognised legal limit? We doubt whether any of the German police would be found in his way, especially if the road had many turnings.

Accident at Eastbourne.

It is to be hoped that visitors to Eastbourne will not be unnecessarily alarmed by the motor-car accident which has happened near that pleasant place. A party of ladies and gentlemen were returning from a visit to Hurstmonceaux Castle. All went well until they were proceeding down Wartling Hill on the way to Hailsham, when the driver in avoiding a dog in the middle of the road ran into a bank. The result was that the car overturned, and three or four of the passengers were badly hurt. Dogs are a fruitful source of annoyance to motorists on the road, and have been the cause of many accidents. But we would emphasise the fact that such an accident should not be urged against automobilism.

A Service at Barry.

MR. T. G. GOULD, of the Windsor Hotel, Barry Dock, proposes to run a large motor-car from his hotel to Barry Island and back at a charge of 3d. for the single journey. The Licensing Committee of the Barry District Council have had a trip on the vehicle, and should no objection be made by the

owners of the horse-drawn brakes in the district the car will shortly ply for hire. It should prove of great service to the locality.

Five to One.

NOT often is the ordinary business meeting of a company made the occasion for such levity as that shown by Major-General Fellows at the gathering of the Motor Traction Company the other day. So convinced is he that the concern will be in liquidation in two years that he offered to bet five to one upon that event. Equally sure of the major-general's error one of the directors accepted the hazard, and both parties are now prepared to wait till the next century is two years old so that time may decide the issue.

Road Improvement.

FOLLOWING the paper by Professor Hele-Shaw at the British Association, which is reported in another column, Mr. J. Brown gave a description of the viagraph, an instrument for testing the unevenness of road surfaces. It is practically a "straight edge" to be drawn along the surface of the road. A wheel rises and falls with the irregularities of the surface, and automatically actuates a pencil making a profile of the road surface on a paper strip. In the discussion Major-General Webber spoke upon the importance of the subject to military authorities, and Sir William Preece, speaking of the effect of speed on traction resistance, said that the resistance rapidly diminished with increasing speed, and the ascent of a hill was expedited with less work if one did one's utmost to get up the hill quickly. Mr. Worby Beaumont discussed the condition of road surfaces in connection with the question of traction, and complained that so many local authorities adopted a penny wise and pound foolish policy in regard to the making and maintenance of roadways. Local authorities did not sufficiently realise the economic value of paying attention to small repairs. Mr. Beaumont suggested that it would be an economical national expenditure if a hundred millions were laid out on the general improvement of the common roads of the country, particularly in cutting down hills and in filling up hollows. Professor Hele-Shaw, in his reply, said he had calculated that there were a hundred thousand miles of highways in this country, and thought if roads were improved and the speed of traction doubled many millions might be saved annually.

Competent Repairers.

THE difficulty of obtaining really satisfactory repairs to motor-vehicles is keenly felt in many districts. Engineers and others profess to be able to put things right, but, unfortunately, many so-called repairers have little practical acquaintance with the automobile. To ensure proper attention to their machines when in need of adjustment, etc., the De Dion-Bouton Syndicate, Limited, is appointing official repairers for their motor-cycles, voiturettes, and cars. From these spare parts will also be obtainable. Provided every care is taken to ensure that only really competent persons are put on the list, this should be a useful enterprise.

Bournemouth Motors, Limited.

WE should imagine that one of the best managed public services in the kingdom is that at Bournemouth. The smartness of the drivers is only equalled by the clearliness and brightness of the vehicles. The service is a regular and constant one; nine waggonettes are in use, and twelve thousand passengers are carried every week. The garage is a commodious one, and well equipped with tools for repairing work. Our photo

shows one of the cars with Mr. Bell, managing director of the concern, at the helm.

A Week End Trip.

LONDON to Bournemouth (a distance of 109 miles) via Ripley Road, Guildford, Farnham, Alton, Winchester, Southampton, and Lyndhurst, is an ideal day's run, especially with the roads in their present fine, although dusty, condition. Our party last Saturday started early, breakfasting at Guildford, lunching at the "Dolphin," Southampton, and reaching our destination at four o'clock in the afternoon. The road between Alton and Winchester was looking its best, and the way over Windmill Hill, between woods of wild cherry trees, sloe, hawthorn, and alder bushes, all laden with berries; hazels, with nuts; coloured brambles, with ripening fruit; eating and horse chestnuts, towering above the rowan trees, with their gracefully hanging red berries, was delightful. The scene was completed by the waving carpet of bracken and bushes so thick in the background. The roads in the New Forest are at their best just now, and the trees are commencing to shed their leaves and put on their autumn plumage.

Return to Town.

SUNDAY was spent quietly resting at Bournemouth, and the return journey to town was commenced about nine o'clock on the next day. Excepting stoppages at Christchurch, to see the Priory, Winchester, and Alton (a town where we had luncheon, and where we shall not stop again), London was reached without incident at six o'clock. Round about Winchester there was a veritable plague of fluff from the thistles and dandelions, the air being white with the "pussy cats" as if it was snowing. Of cars on the road on the downward journey we met a Benz, three passengers and luggage; a tricycle, with trailer, carrying two heavy men and luggage packed behind; and three De Dion voiturettes. On the return journey we did not meet a single motor-vehicle.

Our M.M.C. Panhard.

OUR English Panhard is affording us great satisfaction. It has been in constant use for some weeks for touring, and we find it gives an almost regular average of sixteen miles per hour. The only stoppages on the Bournemouth journey were for our own convenience. The car is as silent and easy running as one as we have ever ridden on, and we are pleased to record this testimony to the excellence of the latest type of vehicle furnished by the Motor Manufacturing Company.

Lafayette, the Necromancer.

THIS gentleman is not only a clever conjurer, but he is certainly a past master in the art of obtaining publicity. Scarcely a paper can be picked up that does not mention his silver-bodied car, which he avers can travel at a mile a minute. Returning from Bournemouth, and passing up Shaftesbury Avenue, the gentleman referred to was just then leaving the Hippodrome on his Locomobile steam-car, with a passenger by his side and his dog on a seat in front. Seeing our car he followed us up Shaftesbury Avenue, down Gower Street, and round to our residence. Although he was steaming pretty hard and Gower Street was fairly clear of traffic, he did not catch us up until our car had landed us at our destination; and we do not claim that our car travels a mile a minute.

Motor Fire-Engines.

ALTHOUGH New York and Paris have adopted motor fire-engines, the fire brigade authorities of London and our other large towns do not seem so encouraging in their views of the new movement. On each engine employed by the Metropolitan Fire Brigade three tons is carried. Speed is an absolute necessity, and so far nothing combining both qualities has yet been shown in English motor-work. What the authorities require is a motor fire-engine that will carry weight, travel at a great speed, and also do the pumping when the fire is reached. There is a splendid chance for the constructor of such a vehicle. Meanwhile we hear that Mr. C. T. Crowden, of Leamington, is converting a 360 gallon steam fire engine which is at present drawn by horses into a self propeller, using steam to supply the propelling apparatus from the existing boiler.

Nervous Councillors in Essex.

WHY are the councillors of Chelmsford so nervous with regard to motor vehicles? Really they ought to be given a ride on cars and treated to an application of petrol by way of soothing syrup. The other day the motor vehicle owners of Minneapolis treated the County Commissioners to a country run. Thirteen vehicles made the start, going to Wayzata, on the shore of Minnetonka Lake. On their return dinner was served, after which came an informal discussion on the subject of good roads and the need of them in the country around Minneapolis took place. Something of the same kind will have to be done for the Chelmsford Town Council, whose fears are distressing indeed. They instructed their town clerk to write to the chief constable of the county with regard to the speed of motor-cars, and he replied that it would be useless to take proceedings unless it could be clearly proved that some person's safety had been endangered. This has not satisfied the Town Council, and further correspondence is to be conducted with the chief constable on the subject. Why cannot the Chelmsford councillors be content with the power to take proceedings when dangerous driving is indulged in—and not seek to irritate and annoy under ordinary conditions?

Racing in Italy.

THE most important of the series of automobile races at Brescia, Italy, was decided on Monday last, under most unfavourable conditions, for the roads were in a positively dangerous state by reason of the recent downpours of rain. The distance covered was 223 kilometres (140 miles), and the route a

circular one from Brescia and back by way of Crémone, Mantone and Vérone. The race was completely marred by the fatal accident which occurred to Caffarati Attilis, one of the competitors in the motor-cycle category, and which came about at a nasty corner, where the road surface was particularly slippery. After a terrible side-slip the machine turned over, and the unfortunate rider was thrown violently against a tree, and suffered a concussion of the brain, from which he shortly afterwards succumbed. The official results were as follows:—Motor-bicycles.—1, Masserati, in 7h. 20min. Motor-tricycles.—1, Soucin, in 3h. 52min.; 2, Noury, 4h. 23min.; 3, Gasté, 4h. 55min.; 4, Sanguinette, 7h. 49min. Motor-quadracycles.—1, Monti, 6h. 15min.; 2, Benedetti, 6h. 57min. Voiturettes.—1, Nagliati, 4h. 9min.; 2, Frascini, in 5h. 52min.; 3, Isalta, in 5h. 55min. Cars (two-seated).—1, Franchetti, 4h. 9min.; 2, Lancia, 5h. 7min.; 3, Tometti, 6h. 12min.; 4, Marchand, 6h. 33min. In all fifty-eight competitors put in an appearance at the starting post.

Motor-Car Upkeep.

MANY are the silly statements circulated with regard to the cost of keeping a motor-car, and varied are the sums actually spent by those who own cars. The subject has been discussed in the *Field*, which calculates £35 for a set of tires, which will last for 6,000 to 8,000 miles with ordinary care. Fuel and lubrication is said to be a halfpenny per mile in most cases. Allowing twice that amount the cost of riding 6,000 miles is £25. Then comes the wear and tear of the transmission gear. Now it is true that in some cars this is not equal to the requirements of the case, and may need renewing at the end of a season but if only made sufficiently strong at the outset the gear should be equal to 30,000 miles of driving. The owner of a car worth, say, £800, would probably engage a skilled mechanic to relieve him of all worry in connection with the keeping of the car in order, and the *Field* puts down a wage of £3 a week as the biggest item in the building up of the expense. Occasional repairs and the cost of batteries, if electric ignition be employed, have also to be considered. So far from motoring being a "pastime for millionaires" alone, says our contemporary, it may be asserted with perfect safety that many existing automobilists manage to keep a car in running order with no more help than that of a boy. They give, say, from £200 to £400 for the car, and so far as the cost of running goes, it does not by any means follow that they cover so great a distance as six thousand miles a year. This is far in excess of what a horse and brougham would be expected to accomplish. To make a fair comparison, the cost of automobile driving should be measured only against the distance which a horse-drawn vehicle of similar size would cover in the year, and the use of the car would then come out considerably cheaper than that of the conventional mode of locomotion.

In Lovely Devon.

REVERTING to recent tours in Devonshire, the following distances may be useful to automobilists who intend to spend a few days in the land of Lorna Doone. From Bridgwater, Watchet is 17½ miles, Minehead, 28½ miles, Porlock, 32½ miles, and Lynmouth, 44½ miles. From Bridgwater to Barnstaple is another interesting run. Thence to Bideford, with its memories of Kingsley, is 9½ miles, and a trip can also be made, via Westward Ho, to a place associated with Mr. Rudyard Kipling's latest work. The whole district is rich with interest and the roads are capital for motoring.

A Necessary Distinction.

A CRAWLEY correspondent sends us a cutting from the contributions of some sapient scribbler to the local paper. This gentleman declares that "motor-cars are becoming an absolute nuisance on the roads"—just as though they would be in place in a drawing-room or on a pier pavilion—and then says that

"many hundreds of them run through Crawley, poisoning the atmosphere and frightening horses and pedestrians alike." To remedy this it is suggested that the police should be "a little less lenient towards motorists." Such vapourings are becoming trite and commonplace. Our contemporary should tell its scribbler that if motor-cars are a nuisance they are becoming quite as necessary as newspapers, and that if they poison the atmosphere that is a matter for the officers of health and not the minions of the law. The distinction between pollution of the atmosphere and frightening nervous old ladies should be clearly stated even in casual gleanings.

The Motor-Car Journal Challenge Cup.

THE accompanying illustration depicts the *Motor-Car Journal* Challenge Cup, lately presented by the proprietors of this paper to the Automobile Club of Great Britain and Ireland as a perpetual trophy for a five-miles race for touring motor-cycles. The cup is of solid silver, and, as will be seen, is handsomely chased. It was first competed for on June 30th last on

the track at the Crystal Palace, when three competitors started in a five-miles scratch race, the winner being Mr. A. E. J. Steele on a Simpson-Strickland tricycle, his time for the five miles being 11 min. 2½ secs.

The Maintenance of Highways.

It appears from a Parliamentary return just issued that during the year ended March 31st, 1899, the expenditure of the several highway authorities in England and Wales, exclusive of loans, amounted to £2,188,422, and the loans raised by the highway authorities during the year amounted to £29,721, all of which was borrowed by Rural District Councils. The expenditure on the repair of roads other than main roads in the year 1888-89 was £1,218,181, the mileage of the roads being 99,953 miles, while in 1898-99, although the mileage of these highways had decreased to 96,573 miles, the expenditure thereon had increased to £1,632,070. The mileage of main roads in rural districts repaired by the County Councils themselves increased yearly from the date when the Local Government Act, 1888, came into operation, until the year 1895-96, when the repair of certain main roads previously repaired by some County Councils was undertaken by Rural District Councils. The aggregate length of the roads under the supervision of Rural District Councils, Highway Boards, and Surveyors of Highways during the year 1898-99 was 103,747 miles, comprising, according to the returns furnished by those authorities, 7,174 miles of main roads not repaired by the County Councils themselves, and 96,573 miles of district roads (ordinary highways).

Automobile Racing in America.

AN automobile race meeting was held at Newport, U.S.A., the popular rendezvous of American society, on Thursday, the 6th, when it was estimated that at least 15,000 persons were present. In the first race, the electric vehicle class, Mrs. Hermann Oelrichs' car, in charge of Mr. S. Leroy, had a walk-over, there being no competitors. For the five-mile tricycle race, Mr. Harold Vanderbilt entered a De Dion and Bouton machine, driven by a professional, and won in 10min. 30sec. Mr. J. Boiselote was second, in 11min. 40sec. In the five-mile race for electric vehicles, Mr. A. L. Riker, of Elizabethport, beat Mr. Spencer E. Crane, of Boston, by 8sec. Time, 10min. 44sec. Mr. John Jacob Astor, with a steam vehicle, contested the next race, but was beaten by more than half a mile by S. T. Davis, a professional on a racing machine. Time, 10min. 48sec. In a five-mile race between Mr. W. K. Vanderbilt, junr., and Mr. David Wolfe Bishop, Mr. Vanderbilt, who drove his German Daimler, won easily. The time was: Mr. Vanderbilt, 8min. 53½sec.; Mr. Bishop, 9min. 30sec. The closing event was the championship 5-mile race between the winners of all classes, and was extremely exciting. Mr. Vanderbilt won in 8min. 54sec. Mr. Kenneth Skinner, on a tricycle, was second in 9min. 22sec., and Mr. A. L. Riker, on an electric vehicle, was third in 10min. 20sec.

A Move in Norfolk.

MOTOR-CARS and their riders have been the subject of discussion at the Norfolk County Council, the matter having been introduced by Mr. G. Stracey on behalf of the Taverham Bench of Magistrates. In the course of his speech he declared that motorists "all appeared to be dressed alike in indiarubber coats and spectacles," and suggested that all cars should be numbered. Support to his contention was given by Lord Wodehouse, Lord Cranworth and Mr. H. Broadhurst, M.P., the latter of whom called automobilists wild people and asserted that they were becoming intolerable. Mr. Broadhurst having given his opinion of motorists, it would be interesting to have the motorists' opinion of Mr. Broadhurst.

The Duty on Motor-Cars.

MOTOR-CARS of between one and two tons weight have to pay two guineas as a local taxation duty, and those of more than two tons weight have to pay three guineas annually, in addition to the ordinary carriage tax. According to a return just issued by the Local Government Board, the total sum received on this account during the year ended March 31st last was £469 7s., a sum which represents 223 vehicles of the smaller weight or 149 of the larger. Of course, the amount was divided among vehicles of both classes. In the London county area £158 11s. was paid in duty, Hampshire coming next with £31 10s. In twenty-seven of the sixty-two administrative counties no duty was paid, so that the average revenue in each of the other twenty-seven was £13 1s. 4d. The county borough drawing the most money from motors was Newcastle-on-Tyne, the amount being £45 3s.; and Brighton and Leicester tie for second place with £18 18s. each. In fifty-two out of the sixty-four municipalities no tax was paid, and the average receipts in each of the remaining twelve were, therefore, £9 14s. 11d. In the whole of Wales only £10 10s. was collected—all in the counties of Cardigan and Glamorgan.

Sports at Vincennes.

IN spite of the counter attraction offered by the Fête des Fleurs at Champ de Mars, a goodly crowd journeyed out to Vincennes on Thursday, the 6th instant, when the usual weekly race meeting was held, and they were rewarded by witnessing some capital sport. Following the custom adopted in connection with these Thursday meetings, the programme was diversified in the extreme, and several items were of quite an

extraordinary nature. Among them I may cite, writes our Paris correspondent, a stilt race, a barrel rolling race for the championship of the world, a hoop trundling race for bicyclists, and a match between two stilt walkers and the legless champion, Hasslinger. Automobilists were principally interested in a couple of events for both of which eleven competitors had sent in their names. The first of these was a ribbon race for voiturettes, which resulted as follows:—First heat: 1, Wrard, 3m. 23sec.; 2, Ricard. Second heat: 1, Denesle, 3m. 29sec.; 2, Sancho. Final: Ricard, 4m. 35sec.; 2, Denesle. The distance was 1,400 mètres. The second event was an ordinary race over a course of 2,400 mètres, and two categories were provided, the final being decided between the leaders of each class over a distance of 4,800 mètres. Wrard, Montier, and Vinet were the placed men in the class for 3 h.p. motors, and in the category reserved for the larger engines Denesle, Marcel, and Ricard finished in the order named. Denesle gained the final, followed home by Wrard, Montier, and Marcel. These Thursday fêtes really afford capital amusement, and they are doing much to brighten up the unfortunate Vincennes annex.

Motor Dust-Vans in Chelsea.

DURING the past week a copy of the Forty-fourth Report of the Vestry of the Parish of Chelsea has come to hand, and glancing through it we came across a reference to the motor dust-vans recently acquired by the Vestry on the recommendation of Mr. Thos. W. E. Higgins, A.M.I.C.E., the surveyor. In his report this gentleman remarks: "The Chelsea Vestry has probably completed its last whole year of administration, but that year will always be remembered as the one in which a much needed improvement in methods of cartage was initiated by them. Ever since the autumn of 1895, when it was announced that Sir David Salamons would organise an exhibition of horseless carriages at Tunbridge Wells, I have taken the greatest interest in the new means of locomotion which was evidently about to establish itself upon a firm footing (if that may be said of a form of traffic which dispenses with horses' hoofs) before the close of the century. At that time I made inquiries and obtained sketches and estimates, but after considering them carefully did not feel justified in bringing them before the Vestry. The next year I made further inquiries, and in November, 1897, the Vestry instructed me to make investigations and report fully to them. I reported in March, 1898, and from that time to February last I was from time to time making various investigations and reports, with the result that on February 13th the Vestry ordered two new motor-vehicles to my specification from the Lancashire Steam Motor Company, of Leyland, Lancs., and one vehicle from the Thornycroft Steam Wagon Company, which had been in use for some little time but which had been overhauled, and was having a watering body fitted to it. Before the end of the Vestry's year this vehicle had been delivered and was working in Chelsea." Mr. Higgins adds, with pardonable pride, that "this was the first motor-vehicle for municipal purposes bought by any local authority within the metropolis."

Automobile Accommodation.

AN account of a new residence for a wealthy American in St. Paul, Minn., refers to an automobile and bicycle room on the basement floor, from which an asphalt drive leads to the street. The apartment is to be fitted with a work bench, and the cement floor will have a sink in the centre, so that the vehicles can be thoroughly washed and the water readily passed away. The idea, although chronicled in large type in our American contemporaries, is by no means new, and the Hon. Evelyn Ellis has, as we illustrated in a recent issue, most complete automobile accommodation, while at his Knightsbridge residence the Hon. C. S. Rolls has a combined motor-carriage house and workshop. The time will probably come when every country house of any importance will have its convenience for automobiles—not only those of the owner, but also those of friends who may be staying on a visit.

The Marot - Gardon Voiturette.

FIG. 1.—GENERAL VIEW OF CAR. (See page 472.)

MOTOR-CAR TRIP.

FARNHAM TO BATH.

THE following account of a run by Mr. John Henry Knight on his Benz car is of interest to motorists as indicating a capital trip, and of use to the public in giving practical information as to the cost of touring in this way. Mr. Knight was accompanied by his two eldest sons.

Leaving Barfield on a Wednesday at 10 a.m. we ran (says Mr. Knight), without stopping, to a few miles north of Basingstoke, where, to obtain a supply of cooling water, we ran into the village of Sherbourne St. John. This caused a slight delay. The roads in this district not being always provided with sign-posts, we had frequently to stop and inquire the way. Newbury was reached about 1.30. After lunch we ran through Savernake Forest to Marlborough, where a stop was made to visit the College, and for tea. We then ran on to Calne, stopping to inspect the curious mound or earthen pyramid known as Silbury Hill. Starting from Calne next morning, a run of 1 hour 55 minutes covered the 18½ miles into Bath. This part of the road is very hilly, and the straggling suburbs of Bath and two or three villages had to be passed through at a comparatively slow pace. The day was spent in seeing the sights of Bath, and in the evening we ran back to our quarters of the previous night, the Lansdowne Arms Hotel, at Calne. Next morning we left the main road to visit Avebury, to inspect the Druidical circle and quaint old Saxon church; then through Marlborough, and up an extremely long hill to Savernake Forest, which the road book states is one mile in length and rises 250 feet. Up this the car went in nine minutes, then a run over a splendid road to Newbury, where some time was spent in looking round the town and refreshing man and car. Then along the valley of the Kennet, passing Thatcham and Theale, to Reading, and with two or three stops to oil the car we reached home soon after seven o'clock, having run 176½ miles in the three days.

On the journey 6½ gallons of petrol were used; that is one gallon to 25½ miles, and as a gallon of petrol can be bought for one shilling and threepence, the cost works out as 3.5ths of a penny per mile. Of course when petrol is purchased in out of the way places in small quantities, eighteenpence is often charged for it. To make a run like this of an average of nearly 60 miles a day, the car must be carefully looked after; when a stoppage is made bearings should be felt to see if any are heating, lubricators must be filled and examined to see if they are working properly, and several other things that the motor-car man will soon find out for himself must be done. Half an hour or three-quarters of an hour must be spent in looking over the car, cleaning the engine, and filling lubricators, before the start is made in the morning.

No sane man would go for a driving tour without seeing that his horse was properly fed and cared for when the day's work was done; and it is the same with the motor car. Treat the car well and it will do its work well. I may add that on this run there was no attempt to cover long distances in the day; our trip was for pleasure, not record breaking.

MR. D. M. WEIGEL, writing from Springvale Terrace, Hammersmith, W., asks us to mention that he has disposed of his holding in the Automobile Association, Limited, to Dr. Lehweß, and has now no connection with the firm.

A MEETING of motor-cyclists was lately held in Boston, U.S.A., when a club was formed under the name of the Associated American Motor-Cyclists.

WITH reference to the electrical cars which the Automobile Manufacturing Company, Limited, have on hand, mentioned in our last issue, Mr. W. C. Bersey, the managing director, writes us that these are not Columbia but Cleveland vehicles, for which they have the sole rights in the United Kingdom. It will be remembered that we published a description of this type of car in our issue of July 28th last.

THE MAROT-GARDON VOITURETTE.

THE attractive-looking car illustrated in Fig. 1 (page 471) is stated by the makers to be intended to meet the demand for a vehicle intermediate between the high-priced cars built by the large firms in France, and the light and often fragile voitu-
rettes. The motor is of the horizontal, water-cooled, double-cylinder petrol type. The bore of the cylinders is 3.4 inches and the stroke 4.8 inches, the normal speed being 700 revolutions per min. The rating of the motor is 4½ h.p., but it is claimed that on the brake they will develop from 4.7 to 4.9 h.p. The ignition is of the regular electrical type, and can be varied at will. A little switch in the circuit is placed on the steering hand-wheel, and permits the operator to stop the sparking instantly. The carburettor used with this motor is of the constant level type. The levers for advancing the ignition, and for regulating the carburation, are located just below the steering hand-wheel, as will be seen from Fig. 2. A special rotary pump is employed for circulating the water. It consists of a chamber in which two meshing spur gears rotate. The water enters at one side of the chamber, and is carried along by the teeth of the gears

FIGS. 2 AND 3.—ELEVATION AND PLAN OF FRAME OF MAROT-GARDON VOITURETTE.

around the surface of the chamber, emerging at the side opposite to that at which it entered. The little pump, which weighs only 7½ lb., is driven by a chain at 800 revolutions per minute, and it will lift the water 24 in. As will be seen, a radiating coil is fitted around the bonnet over the engine in the fore part of the vehicle.

Coming now to the transmission mechanism, it may here be stated that three forward speeds—five, nine, and twenty-two miles per hour—as also a reverse motion, are available. A plan of the complete frame is given in Fig. 3, from which it will be seen that the motor is located in the fore part of the same. The motor shaft is geared to a side shaft *A* by bevel gear. The shaft *A* transmits the power to a Megy friction clutch *B*, the shifted sleeve of which is operated by a foot lever. The friction clutch lever is so connected to the brake lever that when the latter is operated, the clutch disengages automatically. The shaft *D* ends in a squared portion *E*, on which slides a double bevel pinion, used for reversing the motion of the vehicle. The shaft *J*, which receives its motion through the bevel pinions *F* or *G*, carries three friction clutches, *K*, *L*, and *M*. Each of these clutches has attached to it a spur gear, which engages with

a corresponding spur gear on the differential shaft *N*. At the middle of this shaft will be noticed the combined differential gear and brake drum (Fig. 5), and at the ends the sprocket wheels which transmit the power by chains to the rear wheels. It will be noticed that there are three disconnecting couplings in series between the engine and the wheels, viz., the friction clutch *B*, the double bevel gear *F*, *G*, and the friction clutches *K*, *L* and

FIG. 4.—ELEVATION OF MAROT-GARDON MOTOR.

M. As a special advantage of the friction clutch speed change, it is claimed that when going at full speed, and throwing in the low-speed gear, the motor can be made to act as a very powerful brake. All the gears and clutches are enclosed in a casing, provided with doors to permit easy access and inspection. The operation of the friction clutches is effected by means of a rack and a gear sector.

The Megy friction clutch *B* deserves special mention. It consists of an outer drum to which the gear is fastened, and which ordinarily turns loose on the shaft, an inner expandable ring, and a casting keyed and pinned to the shaft. The expandable ring carries two lever supports in which are hinged single-arm levers, with fulcrum on opposite ends of a pin passing through the casting. At the extremity of the levers pins pass through them, which act as guides for coiled springs. These springs are contained in hollow cylinders open at one end, and slide in a drilled hole in the casting. A tapered pin forced between these cylinders will act on the levers through the intermediary of the springs, thus expanding the ring and making it grip the outer drum.

FIG. 5.—VIEW OF VARIABLE-SPEED GEAR—MAROT-GARDON VOITURETTE.

The steering gear is operated by means of a hand-wheel fastened to an inclined steering rod. This rod is provided at its lower extremity with a pinion engaging with a gear sector on one arm of a double-armed lever. The other arm of this lever is joined to the lever of the steering spindle by means of a connecting rod or link.

The frame is of V-iron, assembled in such a manner that the longitudinal pieces form a flush joint with the transverse pieces, the whole being rivetted together by means of elbows of sheet

steel. The frame is suspended by four semi-elliptic springs. Distance rods are attached to the rear axle and to the gear box. The distance between the rear axle and the differential shaft is, therefore, not altered by the tension of the chains, but remains always the same. A feature of the pivots of the steering spindles is that they slant rearwards, for which it is claimed that corners may be turned at high speed within a diameter of 25 feet. Ample brake power is provided, while wooden wheels shod with pneumatic tires are fitted. The car is made by the Etablissements Marot-Gardon, of Paris, for whom Messrs. Wm. H. M. Burgess, Limited, 21, Charterhouse Street, London, E.C., are the agents in this country.

MOTOR-CAR TRACK RACING AT OSTEND.

(From Our Own Correspondent.)

SATURDAY, September 1st, was the date selected for the inaugural automobile meet on the Ostend Motodrome, but so deplorable was the weather that the organisers found it necessary to postpone the racing until the following Monday afternoon. Even then the various events were decided under atmospheric conditions far from pleasant, the wind in particular being very violent. But, in spite of these circumstances, upwards of six thousand spectators assembled upon the Wellington racecourse to witness the competitions, and their courage was rewarded by witnessing some exciting racing. The course is 2,700 mètres in length, and the starts and finishes were effected directly in front of the grand stand. From the starting point the competitors had a straight run of 850 mètres before entering the first bend, which continued for 600 mètres, the succeeding corners being equally easy, and calling for no diminution of speed. The track is perfectly level, and has a grass surface, which proved particularly binding after the rain of the previous days, in spite of the attention given to render it firm and hard. As will be seen from the figures quoted below, no speedy performances were made, the nature of the surface destroying all possibility of the accomplishment of really fast times, for, in addition to its binding nature, the track was very defective, ruts, clods of turf, and patches of broken ground rendering the attainment of high speeds a matter of difficulty.

But all the same the meet proved a great success and clearly demonstrated that automobile racing on a large track will attract the public. The faults and failings of this initial effort are mere details which can be readily rectified, and the more important questions have been satisfactorily answered by the Ostend experiment. The public followed all the phases of the various events with the liveliest interest, and were as vastly amused at the numerous breakdowns of the competing vehicles as they were impressed by the great speeds shown by the mounts of Beconnais and Levegh. The organisers of the meet were Baron Van Loo, the Marquis de Nieulant, and M. Le Bon, and their programme was an excellent one in every respect. First on the list came *La Course Nationale*, open to Belgian voiturettes not exceeding 500 kilogrammes in weight. The distance was five laps, or 13,500 mètres, and the number of starters five. At the very start of the race the leather driving belt of M. Marting's car came off, but a rapid readjustment enabled that competitor to quickly start in pursuit of his rivals, whom he eventually caught and passed. His time for the complete distance was 23min. 30sec., and he was followed home by Vasseur, de Benkelaer and Peschard in the order named. Maughan did not finish. Then came the turn of the motor-cyclists, and for this event, over a distance of 19,500 mètres, Beconnais, Marcellin, Gasté, Fournier, Demester, Lodé, Rigal, Bertin, Lopard, and Courbe turned out. Rigal was soon finished with, and the superior speed of Beconnais' machine quickly carried him to the front, which position he retained until but 500 mètres from the winning post, when a stupid accident deprived him of the victory almost within his grasp. Gasté, Marcellin, Fournier, and Demester had meanwhile been struggling desperately for the second place, which Marcellin ultimately secured. The final result was—1, Marcellin, in 21min. 8½sec.; 2, Demester; 3, Fournier; 4,

Gasté. With the termination of this race the way was cleared for the international voiturette event of five laps, or 13,500 mètres. The weight limit was fixed at 400 kilogrammes. The favourite was Marcellin, and from the start this *chauffeur* went right away from his rivals. But after covering some 5,000 mètres his left back wheel came away from the axle, and although replaced with all speed Marcellin could only secure the fourth place in the list of prize winners. The winner was found in Oury in 19min. 27sec., Van Langendonck and Marting being respectively second and third. The last item on the programme was the twelve lap race reserved for big cars, and great interest was manifested in the *rencontre* of Levegh's Mors racer and Jenatzy's car, which holds the record for the kilomètre with flying start. It may be remembered that this record was achieved upon June 17th last, the Sunday following the Gordon Bennet Cup races, and that the time then accomplished was 38½sec., representing a speed of 94 kilometres (59 miles) per hour. Unfortunately at Ostend Jenatzy's racer proved obstreperous from the start, and he was ultimately compelled to abandon. Carillois-Renaux, who was also driving a high-powered car, found himself in a similar plight, and all the other competitors, excepting Levegh, experienced troubles. The latter, therefore, won easily in 38min. 48½sec., his nearest rival, Phillipe, being then some 13,500 mètres behind. The third man was Broc, and Crawhez finished fourth.

It is doubtful whether, even with special preparation, the ordinary race-course can be rendered fit for automobile racing, but on a track reserved for the sport one would see some grand struggles. As regards size, I fancy that a track of two miles to the lap would be found to be about the thing, for larger than this much of the racing would be lost to the spectators, while a smaller course would necessitate considerable banking at the corners and would produce confusion in one's efforts to follow the fortunes of an event. Much would have to be carefully considered and the regulations elaborately prepared before racing of this description could be indulged in under perfect conditions, but with the success of the experiment at Ostend I think that serious attention will be given to the question, and that one may expect great developments in this direction in the future.

CORRESPONDENCE.

A MOTOR-CAR DRIVING SCHOOL.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—May I inform your correspondent, Mr. Harper, through your columns, that a school such as he suggests will be re-opened on October 1st, after the summer holidays, at the appended address. Intending motorists will then be able to go through a course of driving, first in the school and then on the road. The school has a floor space of 4,000 square feet. Petrol will be obtainable, spare parts carried, and repairs effected.

Yours truly,

AUGUSTINE J. NEVILLE.

21, Abingdon Villas, Kensington,
September 10th, 1900.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—With regard to Mr. Dando Harper's letter in your last issue, I may point out that he has, within a stone's throw, what he requires—i.e., Tufnell Park Track and Grounds, which are used for the purpose by the Gordon Cycle and Motor Company, of Holloway.

Yours truly,

H. JOHNSON.

1, Dyer's Buildings, Holborn, E.C.,
September 11th, 1900.

IN London the lessening in the number of horses that exhibit fright at passing a motor-carriage is very noticeable, according to the *Court Journal*.

CONGRATULATIONS to Mr. Percy Richardson, the London manager of the Daimler Motor Company, Limited, on his marriage, which, we understand, took place in Dublin on Wednesday last.

THE PACKARD PETROLEUM-SPIRIT-MOTOR-CAR.

AFTER a thorough course of preliminary experiments, the New York and Ohio Co., of Warren, Ohio, U.S.A., who are well known as the makers of the "Packard" incandescent lamps and transformers, lately brought out a new petrol vehicle embodying some interesting features. The car, which takes the form of a four-seated dog-cart, is solidly built, to endure high speeds on rough roads. The road wheels are both 34 in. in diameter, with 3-in. pneumatic tires. This diameter of wheel was preferred to a smaller one, as it is claimed to improve the running and steering qualities of the vehicle; and as front and rear wheels are alike, the rear tires can, if desired, be put on the front wheels when too far worn to be of further service for traction. The gauge is 4 ft. 8½ in.; the frame is of seamless steel tubing, made flexible by ball joints, so that any wheel can rise independently of the rest. Double elliptic springs support the body at the rear, and a reversed elliptic spring carries the front end. The engine is of the horizontal, single cylinder, four-cycle type, with a high compression for full load and a throttling control. The motor is designed to run at a normal maximum of 800 revolutions, and at this speed, with a full charge, it will give 9 h.p. on the brake. A spring transmission is interspersed between the engine and the gear shaft,

which prevents binding in the bearings and relieves the wheels of the "kick" of the explosion. Electrical ignition is adopted. A gear and chain drive is used. The reverse is a slow speed, giving, with varied speeds of the engine, from six to ten miles an hour. The hill-climbing gear is approximately the same speed. The high or working speed gives a range of from seven to twenty miles or over per hour, dependent upon the speed of the engine. The latter is controlled through a pedal operated by the right foot of the driver. The two forward speeds, the reverse and the brake, are controlled by a single lever at the right of the driver. Any one of these operations can be performed by the lever instantly, it not being necessary to pass through the intermediate functions. Thus, if the brake has been applied and it is desired to put on the high speed at once, it is not necessary to pass through the slow speed, which, if the carriage was running, would make a very unpleasant, if not dangerous, check to the speed. Steering is done by a lever held by the left hand. In addition to the hand brake, a powerful foot brake acting on the rear axle is fitted. Arrangements are provided whereby the distance between the centres of the chain wheels is maintained constant, irrespective of the relative motion of the carriage and the rear axle.

The New York and Ohio Company have furnished us with a photo reproduced herewith showing their latest production. The appearance and general design of the vehicle are the same as the standard Packard car. The special vehicle illustrated is, however, more powerful and adapted for higher speeds, having in fact been designed to compete with the high priced French cars. A single-cylinder engine which will indicate 12 h.p. on the brake at its maximum normal speed of 800 revolutions per minute is used. Four speeds ahead—varying from six to thirty or more miles per

hour—and two speeds backwards are available. As in the standard car there are no idle gears in operation when the vehicle is running on the higher speeds. The speed in running is controlled by throttling the engine. The sparking, which is of the high-tension type, is automatically controlled, a sensitive automatic governor adjusting the spark so that the explosion takes place at exactly the proper point in the stroke for the speed at which the motor is running. The car is fitted with a new rim brake, an auxiliary brake rim being fitted on the inside of the rims of the rear wheels on which large brake shoes are applied. This is said to be exceedingly effective, durable, and absolutely safe arrangement, even if the rear axle, differential, and chain should all give way. The usual band brake on the forward counter-shaft is also provided, and this is operated by a single hand-controlling lever. The rim brakes are operated by an auxiliary foot lever. Inclined wheel steering is fitted, the makers considering this essential for a high-speed machine, although probably not necessary for motor-cars designed to run not over twenty miles per hour. All bearings and oil cups are supplied with oil from a single reservoir, and enough oil and petrol can be carried in the tanks for a run of 150 to 200 miles. The machine is provided with a detachable dos-a-dos rear seat, and is amply strong and powerful to carry four or five passengers. The wheels are all 36 in. in diameter, and are provided with 4 in. pneumatic tires. The frame is ball-jointed throughout, and is accordingly extremely flexible, being designed to stand maintained high speeds on rough roads. The Packard cars are given a thorough test before they leave the factory. The rear or driving wheels of the vehicle under test are supported on a pair of endless belts running over pulleys on two parallel shafts. One of these shafts is provided with a brake pulley, by means of which any desired load can be applied. A tachometer is attached to the engine, indicating at all times the exact speed, and while on this tester numerous indicator cards are taken from each engine. The car is run under varying loads and speeds for one or two days on this testing machine, and is then with a skeleton body taken out for a further and final test on the road. Thus when the finished body of the car is fitted all the mechanism has been thoroughly tested, and is in perfect running order.

A MOTOR-QUADRICYCLE has just been shipped to South Africa by the Waltham Manufacturing Company, of Waltham, Mass., U.S.A.

LONDON correspondents of leading provincial journals are acknowledging that motor vehicles are becoming more and more common in metropolitan thoroughfares. "Looking back no further than three years ago one is impressed," says the *Manchester Evening News*, "by the very notable increase in the number of smart motor carriages to be seen on the streets of London. Two other facts are also apparent—first, that these equipages are handsomer and less noisy than the first examples seen; secondly, that a goodly proportion are driven by ladies. At first the motor was looked on as a somewhat vulgar innovation, but it is now to be seen in the most exclusive neighbourhoods, and its votaries include many arbiters of good form."

EARL RUSSELL has read with great surprise and indignation the convictions at Bow-street against automobilists for causing an obstruction by leaving their motor-cars standing in the street. These are reported on page 482 of the current issue. No doubt, says the Earl, it would be impossible in London to allow an accumulation of waiting carriages in narrow and busy thoroughfares, but do we ever hear of the owner of a landau being summoned while it waits for half an hour outside a door in Grosvenor-square, or of a cabman being summoned for obstruction if he stands in Arundel-street while his fare sees a solicitor? I am astounded that the magistrate should have made no comment on the unreasonableness of the summons. It would appear that both he and the police fail to realise that motor-cars are declared by law to be carriages, and as such are entitled under Highways Acts and Traffic Regulations to exactly the same treatment as any other private carriage.

TO BEDFORD AND BACK.

THE ENGLISH MOTOR CLUB'S RUN.

THE social instinct is strong in automobilists, and although last Saturday's run of the English Motor Club was the scene of strife between motoring canines, it was a very pleasant gathering for all the human beings participating therein. There was no organised start—probably a concession to the "last man," who will always appear just when the rest have got away. All who intended to journey to Bedford were invited to go to Luton and share in the hospitality of Mr. E. W. Hart at Windmill Road, arriving there between four and five o'clock in the afternoon. Such a course proved very acceptable, and, thanks to the kindly consideration of Mr. Hart and his brothers and the several charming ladies who assisted in entertaining the guests, those who got early to the rendezvous were inclined to linger—even when towards 6.30 p.m. the signal was given for the cars to be got ready for the second stage of the trip.

The first to arrive were Mr. J. C. Hill and his party on a Hurtu. Then followed in quick succession a goodly number of cars and motor-cycles, until we were able to count twenty-five vehicles of all kinds. The host's little son was riding about in his electric Sherinette, and Mr. Hart's Panhard was also *en évidence*. Dr. Roberts came over from St. Albans, Mr. and Mrs.

ARRIVING AT WINDMILL ROAD, LUTON.

Edge and the dog came along on the famous Napier car, Mr. C. Jarrott had travelled on a De Dion voiturette, as had also Mr. Roger Fuller. Mr. Holtzafel and Mr. Campbell were among the others who came on cars. A motor-tricycle with a basket chair trailing behind occasioned some notice, and then the arrival of Mr. F. F. Wellington on his 8 h.p. Panhard claimed all attention. Unluckily for the snapshotist, the light was growing weak, or we might have illumined these pages with a picture of how a Panhard car kicks out behind to the destruction of any gates or bars that may be closed against it. Such a demonstration was given by Mr. Wellington owing to his chain breaking. Mr. M. Moyle came along on his motor-tricycle with news of how Mr. T. Maltby, jun., had had a spill, and was even then on the way. Shortly after Mr. Maltby appeared, neither himself nor his motor-tricycle any the worse for contact with Mother Earth. Mr. Ovenden, of Sutton, Mr. A. McCormack, and Mr. Gladding were also in the motor-tricycle contingent, and Mr. Marriott was on a quadricycle. Two Werner motor-bicycles were there, upon which Mr. Leonard and Mr. G. L. Rendell had ridden from town.

A most enjoyable tea was provided, and conversation became general. The roads had been good though dusty, and no mishaps worth retailing had occurred. Again in the yard, where Mr. Hart had thoughtfully given instructions for the cars to be

dusted over before the start for Bedford, everyone was anticipating a good day for the morrow. Suddenly a growling and a barking and a scuffling was heard, and it was seen that the dog from the 16 h.p. Napier car and another of similar type from an 8 h.p. Panhard were engaged in conflict. Evidently one or other

IN THE YARD OF THE SWAN AT BEDFORD.

Photo by) [Mr. C. Jarrott.]

had gone too near the car over which the remaining animal had an eye, and a few uncivil yelps had culminated in battle. The contestants were fierce, and in vain did their owners seek to disengage the dogs until the upholder of the honour of the car of Napier had lain the Panhard representative on the ground with a torn shoulder. But not all the woes lay with the latter, for the Napier dog had a torn ear and a generally unpleasant look about the coat. And when the contest was over a mere horse and cart was requisitioned, Mr. Edge conveying Mr. Wellington's dog to the veterinary surgeon, where he was to remain a few days. Though he then escaped, Mr. Edge's dog was doomed.

Shortly before seven o'clock the journey to Bedford was resumed, the streets of Luton being lined with a great crowd. Just before reaching Barton Mr. Wellington's chain broke again, and in the village itself a local constable made himself prominent but not altogether objectionable. In fact, his antics were amusing. Between Silsoe and Bedford the motor-cyclists had to pedal hard, but all got safely to the Swan at Bedford, where dinner was served.

At Bedford the Birmingham contingent arrived half an hour after the party from Luton, and then it was seen to include Messrs. Harvey du Cros, junr., and J. W. Stocks on a De Dion voiturette, and Messrs. Walter Talbot, Crowdy, Stevens, McDonald

SUNDAY MORNING—NEARLY READY.

Photo by) [Mr. C. Jarrott.]

and Clark on motor-cycles. Mr. C. W. Brown also came along, having got to Luton late. Mr. Chater Lea on a motor-tricycle, and Messrs. Ellington and Bruce had come over on a quadricycle direct from London to Bedford.

Sunday morning opened well, and after the usual overhauling of the cars and cycles the party started for Hitchin *via* Biggleswade. On the way the company "visibly decreased," for whereas thirty-five had dined at Bedford, only twenty-four partook of luncheon at Hitchin, where the organised tour ended, and from whence the various participants made their several ways homeward at will. Most of the party came home by way of Hatfield, and there a regrettable incident occurred. To avoid a passing cyclist Mr. Edge diverted the course of his car, and at that moment his dog fell from his place and got beneath the wheels, being killed almost instantaneously. He has been a familiar figure at every important motor meet of the last few years and was probably nearly as well known to automobilists as his master. Otherwise nothing occurred to mar the delight of the run, and the English Motor Club is to be congratulated on the success of the outing. Another run is in contemplation on the 22nd inst., and Wendover will most likely be one of the points of the journey.

BUSINESS pressure has caused Mr. C. Jarrott to postpone for a few days his attempt to beat the motor-tricycle record.

AN interesting automobile parade was held in Washington Park, Bridgeport, Conn., U.S.A., on July 4th. Forty-two vehicles, of all types and sizes, plain and ornamented, were in line, and their proud occupants were continuously cheered along the route. A number of the vehicles were artistically decorated, and the judges had some difficulty in deciding which was the handsomest decoration and worthy of the silver cup offered as a prize. They finally decided to award it to Miss Emma Guy Pike, who held the lever of a "Locomobile" steam car. The sides of the automobile, which had a sort of a Japanese effect, were covered with crepe paper, Easter lilies and green foliage of the same material. The front and rear of the carriage were extended by ornamental figures, and paper lanterns completed the effect. The steering bar was covered with roses.

FOR a long time it has been our intention to run out to Chalk Farm and have a look over Mr. Frank F. Wellington's motor-car depôt in St. George's Square, N.W., but for one reason or another the projected visit was delayed last week. We were quite surprised at the large number of motor-vehicles on hand, these ranging from a motor-bicycle right up to large Daimler wagonettes. Motor-cars of every description were to be seen, including both early and modern specimens of automobile construction, for side by side we noticed an ancient Benz high-built delivery van and a very elegant Panhard car of recent build. It is not only in the sale of automobiles that Mr. Wellington is interested, but he is well equipped to carry on the repairs of all kinds. In fact, this branch of his business has grown so rapidly that for a long time the men have been compelled to work in excess of the usual hours. Recently he has added to his facilities in this department, and being unable to obtain good English repairing mechanics in sufficient number has had to fall back on French workmen. A good many motorists are under the impression that Mr. F. F. Wellington is connected with the Wellington Motor Company, of Battersea, but in the course of our ramble over the depôt he informed us that there is no connection between the two concerns whatever.

THE ADLER MOTOR-VOITURETTE.

REFERENCE has already been made in these columns to the fact that the Adler Fahrradwerke Gesellschaft (Kleyer), of Frankfort-am-Main, one of the largest cycle-making concerns in Germany, had taken up the construction of motor-cars and cycles. We are now able to give an illustration and a brief description of the two- or three-seated car which has lately been put on the market by this company. From the particulars sent us the arrangement adopted appears to closely resemble that of the Renault cars. The engine—a vertical single-cylinder one of the petroleum-spirit type—is located under a bonnet in the fore-part of a tubular frame. The motor is rated at $3\frac{1}{2}$ h.p.; it is fitted with a water-jacket to both the cylinder and explosion chamber, the circulation being maintained by means of a small pump. The ignition is electrical, while a radiating coil is fitted in the fore-part of the car in connection with the water circulation.

Three speeds are available, those usually fitted being $6\frac{1}{2}$, 14, and 28 kilometres per hour, but these can be increased or decreased by means of the variable electrical ignition. The power of the engine is transmitted to a longitudinal variable-gear shaft by pinions, and thence to the differential rear axle by bevel gearing, no belts or chains being employed. A hand lever controls band brakes on the hubs of each of the rear wheels, while there is a hand brake on the intermediate shaft, operated in conjunction with the friction clutch by a foot pedal. The steering is controlled by a bar on a vertical standard, and the wheels are of the cycle type shod with pneumatic tyres. The petrol tank has a capacity sufficient for a run of 150 kilometres. Before being put on the market the Adler car has, we understand, been submitted to extended trials over all sorts of roads and gradients, the results of which have apparently proved satisfactory to the makers.

THE ADLER VOITURETTE.

THE first Thornycroft steam lorry built in America was submitted for its trial trip at the Cooke Locomotive Works, Paterson, N.J., on the 21st ult. It was under the personal guidance of Mr. Charles D. Cooke, of the well-known engine-building company, who has for years taken a keen interest in the motor-vehicle, and it gave so good an account of itself that others on similar lines will be turned out as soon as possible. A new company to manufacture Thornycroft wagons on an extensive scale will be organised by the Cooke Company and the American agents of the Thornycroft system, Messrs. Thorpe, Platt, and Co., of New York.

IN reply to a correspondent who signs himself "R," the question as to the relative merits of block and roller chains for motor-cars is a much debated one. So far as our own experience has gone, there is very little difference between the two as regards speed and durability. We, of course, only speak of best quality chains. The principal advantage of roller chains over the block type, when they are used without gear-cases, as is generally the case in motor-cars, is that they are less liable to be detrimentally affected by wet, dirt, or mud, the block chain having a decided tendency to tighten when working in an exposed condition in bad weather.

HERE AND THERE.

HOLBORN is becoming known as the Automobilists' Parade, and country folk are beginning to take a walk from St. Sepulchre's to beyond Chancery Lane in the sure and certain hope of seeing a motor-car pass along. One day last week I walked along there shortly after two o'clock, and within a few minutes saw Mr. Mann on his Marshall dogcart; a gentleman unknown on a Benz car; Mr. H. J. Lawson in his German Daimler, the hood attracting general attention; Mr. Mark Mayhew on a fiery looking Renault car; and the steam van of Messrs. Harmsworth, which was a feature of the motor-car exhibition at the Agricultural Hall.

MR JOSEPH PENNELL, whose wanderings by bicycle are well known, has achieved further fame by an achievement with his motor-bicycle. He has just ridden from Paris to Andermatt, crossing the Furka and the St. Gothard Passes for the first time with a bicycle of that description. Probably the result will be another book and more illustrations.

WHEN will cyclists have the sense to withstand the temptation to "hang on" to fast motor-cars? Several accidents have occurred from this cause, and the cyclist has, like the lady invited to become Mrs. 'Enery 'Awkins, "only yerself to blame." The other day Mr. H. H. Sansom, an ex-champion cyclist, was motoring, and a Nottingham cyclist was following close behind. The former pulled up suddenly to avoid some cattle and the latter went down and damaged his knee cap. Probably that has taught him a lesson; will others learn by his experience?

EVERY week brings me news from automobilists on tour of different people catering for their requirements in various places. At Bognor the Cycle Manufacturing Company, of London Road, stock petroleum spirit, and also undertake repairs to motor-cars that happen to require such attention. At Weymouth, Messrs. Pearce and Herbert, ironmongers, are storing Pratt's motor spirit—a fact of interest to all who travel that way.

SLOUGH is seeing some smart things in connection with automobilism. When a serious accident lately occurred at the railway station there, Dr. Bruce Porter rode over from Windsor on his motor-car, arriving some time before the next train from the Royal borough to Slough was due. One day last week another instance of the convenience of the motor-car was given. Some tourists from Windsor arrived at Slough, and found that they were too late to get on to Reading in time to join an express to the north. It was of the greatest importance that they should go by that train, and they decided to charter a motor-vehicle and hasten to the biscuit town. Mr. Fullbrook went to their assistance with his new Daimler wagonette, which reached the station at Reading in time for the travellers to take their seats in the express.

SEVERAL times has it been urged upon the railway companies to consider the automobile as a feeder to their leading systems. There are many out-of-the-way places where a motor-car service would bring the railways and their passengers into close connection, and I am glad to give the above instance as a testimony to the feasibility of the idea. The car was got ready without delay, and went off at a good rate.

THERE was a pleasant little party at the Bow Street Police-court last week, when Mr. Edge appeared as a defendant, Mr. Jarrott as a witness on his behalf, and Mr. Staplee Firth as the good legal friend. Explaining that he (the witness) had gone to Regent Street for his motor-tricycle, Mr. Jarrott told Mr. Marsham, the magistrate, that he caught Mr. Edge up at Rottingdean on the same day—a fact that seemed to startle the worthy man, who evidently regarded it as a novelty, and asked the witness how long it would take him to go from London to Brighton. Mr. Jarrott confessed he

could do it under three or four hours, and Mr. Firth seriously remarked that motor-vehicles went fairly rapidly on good roads. I fancy I saw a twinkle about the eyes of the trio of automobilists concerned, and that they enjoyed the jokelet. Anyhow, I do know that the same Mr. Jarrott has designs on the forty miles in the hour motor-tricycle record, and that he has since travelled the London to Brighton road in — hour — minutes — seconds. Further details might worry the good Bow Street magistrate. Suffice to say that, like the daily runs of Mr. Rolls and Mr. Edge in the 1,000-Mile Trial, the speed was fully up to the legal limit.

THIS week journalists have been meeting in London, listening to papers by day and attending receptions by night. At the Hotel Cecil, on Monday, I noticed many who recorded the doings of the great tour, travelling from their own town a few miles and returning by train. From several little chats I had with representatives of the leading provincial journals it is clear that the "great organs of opinion" are with automobilists, and that it is mainly the "tinkling cymbals" of little importance that are engaged in inciting local authorities and others to harass our movement. The way in which general newspapers have given attention to automobilism is very gratifying to all interested in the problem of locomotion. The service is, however, reciprocal, for automobilism has provided many a readable article and given an interest to the columns of several papers. But newspaper men have much to learn about motor-cars, although the reporter who went to the stand of the Daimler Company at the last exhibition and asked where the electricity was stored in their car must not be regarded as typical of the state of knowledge of the whole profession.

THE Earl of Carnarvon, the Duke of Newcastle, and Lord Louth are not the only titled automobilists. The Marquis of Exeter is also a lover of the motor-car, and often drives himself. He has just had a slight spill while riding at Aswarby. He had ridden over from Butleigh House with Sir George Whichcote, and during the afternoon went for a short trip. When travelling at a good speed the car got on to the roadside and overturned. His lordship was thrown out, but happily escaped with nothing worse than a cut shin and other slight injuries subsequently returned home by train.

THERE are many enthusiastic motorists in East London, and some of them recently arranged for an excursion to Brighton. Five motor-cars were chartered, leaders appointed, and Mr. Lawrence Doyle elected captain. Messrs. T. Maltby, jun., and M. Moyle had consented to pilot the cars on their own motor-tricycles, and everything seemed in a fair way for a pleasant journey. In Railway Street, Bromley, E., the party assembled at 8 a.m.; the cars were due half an hour later. But they came not. At nine o'clock the telephone was requisitioned to the West End depot from which they had been ordered, and the reply came, "Cars are on the way; wait half an hour." At eleven o'clock one car arrived, and great was the disappointment of the would-be passengers. Thirty chagrined men stood on the pavement and solemnly adopted the resolution, "That we proceed to Brighton by train and call on the motor people to pay the extra expenses." Then they proceeded by cabs and trains to London Bridge, caught the train to London-by-the-Sea and denounced all associated with automobilism. They have slept since then, and something of the feeling of irritation has worn off, for a second attempt is to be made on Monday next, and cars have been chartered to take the party to Southend-on-Sea. If the cars do not appear this time some of the trippers will get quite cross—so one of the pilots, who went on the English Motor Club's run on Saturday, told me over the teacups at Luton.

LOLLIUS

ON Sunday afternoon last a motor-car accident occurred at Haxton Brow, near Scarborough. The vehicle ran into a hedge, and the occupants—a lady and gentleman—were thrown.

THE BERLIN-AIX-LA-CHAPELLE RACE.

FOR the first time in the history of German automobilism a long-distance automobile race has been decided, and, it may be added, decided most successfully. It is due to the Westdeutscher Automobile Club that this great event over a route of 700 kilometres, or about 438 miles, was organised and carried out, and that club should always bear the gratitude of German automobilists for the pluck and energy displayed by its members in undertaking such a heavy task as the organisation of an event of this length and importance. For it must be borne in mind that automobile racing is but of very recent date in Germany, and that those few events which have been decided have been run over, comparatively speaking, very short routes. But in the case under notice the conditions were widely different, for the preparation of a race extending from Berlin to Aix-la-Chapelle necessitated an enormous amount of work, all the heavier by reason of the lack of experience by the organisers. The course was divided into four stages, as follows:—

	Kilomètres.
1st day, Berlin, Potsdam, Magdeburg	142
2nd day, Magdeburg, Braunschweig, Moritzburg, Hanover	153
3rd day, Hanover, Munster	188
4th day, Munster, Aix-la-Chapelle	217
	700

Five categories were provided, these being: 1, Motor-cycles; 2, Voiturettes not exceeding 400 kilogrammes in weight and carrying a motor of four or less horse-power; 3, Tourists' two-seated cars weighing more than 400 kilogrammes, and carrying a motor of nine or less horse-power; 4, Tourists with four-seated cars weighing more than 600 kilogrammes, and carrying a motor of nine or more horse-power; 5, Racers with cars exceeding 250 kilogrammes in weight. The prizes offered were numerous and valuable, the winner in the fifth category, for example, taking £95. A start was made on Wednesday, August 29th, at nine o'clock in the morning, from the Berlin Zoological Garden, the actual competitors being:—Racers: Messrs. Bereis and Kraentler. Motor-cyclists: Messrs. Encke, Vogel, Gleizes, Kittsteiner, and Joyeux de Castillon's. Voiturettists: Messrs. Herfeldt, Jeannin, Paul Schleicher, Dassé, Reuter, Otto Kruger, Hewald, Langen, Meyer, Barthelems, Jean Moncet, Dupont, Emile Jeannin, Jager, Schaller, Mertes, and Carl May. Tourists (two seats): Messrs. Ernst Neuss, H. Gal, Isbert, Christian Barth, Fritz Kirchheim, and Ehrhardt. Tourists (four seats) Messrs. Buchner and Mundner. The leaders for the first day were Kraentler, who covered the 142 kilometres of route in 2h. 47min., and Gleizes, whose time was 3h. 5min. The other men well to the front were Kittsteiner, 3h. 25min.; Jeannin, 3h. 38min.; Barth, 3h. 50min.; Kirchheim, 4h. 1min.; and Neuss, 4h. 8min. During the second stage Kraentler's big car broke down for a couple of hours at Koenigs-lutter, which enabled Gleizes to secure a substantial lead, and no competitor could make any impression upon the French racer's commanding advance. Ultimately fifteen of the thirty-two starters completed the course, the official return being as follows:—

MOTOR-CYCLES.

	H.	M.	S.
1. Gleizes	14	46	22
2. Kittsteiner	17	49	36 ³ / ₄
3. Vogel	33	28	39

VOITURETTES.

	H.	M.	S.

RACERS.

1. Kraentler... ..	16	56	24
--------------------	----	----	----

This event has undoubtedly done much to popularise the sport in Germany, and it is to be hoped that it is merely the first of a long series of similar races. The interest shown in the event was not merely confined to automobile circles, but it attracted the attention of, one might almost say, the nation, and it demonstrated that what racing has done for the French industry it would assuredly do for the movement in Germany. May it be given the chance is the wish of all motor enthusiasts.

ACCUMULATORS FOR MOTOR-CYCLES AND CARS.

AMONG the several firms who are devoting special attention to the requirements of automobilists in the way of electrical accessories is Messrs. Peto and Radford Limited, of 57B, Hatton Garden, London, E.C. One of their leading features are accumulators for use in connection with the production of the spark for igniting the explosive charge in petrol motors. The batteries are made in various sizes, ranging from 4-volt 4 ampère-hours for short runs up to 100 miles, to 4-volt 14 ampère-hours for runs up to 500 miles. A convenient size for a motor-cycle is the 4-volt 12 ampère-hour battery, comprising a couple of accumulators, which are made to exactly fit into a standard De Dion battery case. Of these, only one is used at a time, the other being a reserve charging. They also manufacture accumulators for use with engines of higher power. These consist of single cells giving two volts each, and are usually supplied in 4-volt sets, consisting of two cells in a light wood tray. Any number of cells can be used if greater power is required. A set of six cells, consisting of two 6-volt batteries, is recommended as a useful set for chauffeurs to take on tour. Only one set is used at a time, and when this is discharged the other can be put in circuit, whilst the discharged set is sent to be recharged at the nearest convenient charging depot. Messrs. Peto and Radford also supply primary batteries for recharging accumulators, as well as handy little electric inspection lamps, which can be hung on brackets in the carriage, and used for inspecting the engine or transmission gear should such be necessary after dark.

La Locomotion Automobile states that it is proposed to establish an automobilodrome at Salon.

SOME enterprising gentleman has, we notice, acquired one of the electric cabs of the old London Electrical Cab Company, and is now running the same about London.

THE managers of the Berlin permanent automobile exhibition have fitted up on their premises near the Friedrich-Strasse Station a motor driving school for instruction in automobile driving.

THE postmaster of New York City made a test with a Hertel petrol motor-car a few days ago for the collection of mail. The usual carrier went with the motor driver to open the boxes and take out the mail. The first test was confined to the downtown districts, but subsequent trips were made uptown, the results being forwarded to the authorities at Washington.

ANY motorist who finds himself in want of sundries or petrol when passing through London on a Sunday will be able to have his requirements filled by calling on Mr. C. E. Rush, of the London Autocar Company, of Grays Inn Road, W.C. Mr. Rush resides at 74, Clovelly Mansions, close by, and will, he tells us, be only too glad to be of assistance to automobilists in the way named.

MOTOR-CARS IN THE FRENCH ARMY.

(From Our Paris Correspondent.)

FOR a long time past the French military authorities have regarded with favour the automobile for army purposes, and when opportunity occurred they have never failed to utilise the new means of locomotion. In this they have but demonstrated that, unlike the military systems of many countries, the French army has at its head chiefs who are not imbued with old-fashioned conservative principles so detrimental to modern progress. Granted that the sight of a brilliantly uniformed officer astride a motor-cycle may appear somewhat incongruous, still the rapidity with which orders can be transmitted and commands executed by means of the motor is in itself a reason sufficiently weighty to outbalance such minor consideration as the question of appearance. And then, too, there is a field in the army for such a variety of vehicles. Cycles for despatch service; voiturettes and carriages for passenger transport; drays and heavy vehicles for artillery, ammunition, ambulance, medical, telegraphic, and commissariat work, not to mention dozens of other directions in which the automobile may be employed with advantage. Frenchmen appreciate the possibilities of the self-propelled vehicle in a manner unknown in other countries, and French military men are in no way behind their civilian countrymen in this recognition of the motor-car's future. And this appreciation is not a mere senseless belief in the powers of the automobile, for its faults are also known, and strenuous efforts are being made to eliminate them. No, it is a recognition of automobilism as a whole, and the knowledge that only by employment and continual experiments will the cars be ultimately brought to perfection. From time to time I have noted in these columns the automobile trials made in connection with military operations in various provinces in France, but none of these experiments have approached in magnitude those now actually in progress in connection with the great manoeuvres of the Beauce. There the transport service is being practically entirely carried out by self-propelled vehicles, and a variety of types are engaged upon the work. First of all there are a couple of Scotte trains, one of which is being driven by M. Scotte in person. Then there are two De Dion steamers, two Panhard drays, and a couple of similar vehicles constructed by De Dietrich. So much for the heavy brigade, and here I may state that the Government hires these vehicles, paying twenty francs per day for their use, by no means a miserly figure; especially when the importance of the tests for the suppliers is considered. Coming to the lighter types of cars quite a caravan is in use. M. Debray, or Antony, as he is known in racing circles, is in attendance with his 32 h.p. Mors upon General Lucas, and this General has also three motor-cycles at his disposition. General Pendeze has a couple of motor-cycles in addition to the 16 h.p. car of M. Brault. General de Négrier makes use of the 12 h.p. car of M. Fabvier and three motor-cycles. As for the Commander-in-Chief himself, General Brugère, he employs two 16 h.p. cars belonging respectively to M. Journu and M. Brisson, two voiturettes of MM. Marcel and Louis Renault, and has in addition three motor-cycles. All the larger cars carry four persons, and both driver and mechanic are engaged upon their periodical twenty-eight days of service. As may be readily imagined, the greatest interest is being evinced

in these trials, and the official report will be awaited with impatience. A special commission has been appointed to follow the performances of the vehicles throughout the manoeuvres, and elaborate precautions are being taken to ensure an accurate record of their achievements. This is the sort of encouragement that is required, and all honour is due to the French Government, who show their sympathy with the new industry in so practical a manner.

Since the above article reached us we learn that a serious accident occurred at Sauveterre de Guienne (Gironde) on Monday owing to the front pneumatic tire of one of the cars bursting. General Marchal and two other officers were being driven by M. Versein, to whom the car belonged, when, owing to the bursting of the tire, the car skidded and collided violently with a tree. General Marchal was the first thrown out. He was severely bruised in the face, his forehead was fractured, and an eye injured. He also sprained his foot, and was for some time unconscious on the roadside. His aide-de-camp, a captain, was severely hurt in the left arm and hip, but was able to give help to the General and to the owner of the car, who was badly injured in the head and face. Owing to the accident, it is stated in one account that the petrol tank was broken, and that the car was destroyed by fire, but another report is to the effect that only a portion of the framework was damaged. General

Marchal, who was the worst injured of the three occupants of the car, is reported to be gradually recovering.

THE CLUB HOUSE OF THE FRENCH AUTOMOBILE CLUB, PLACE DE LA CONCORDE, PARIS.
(L'Avenir de l'Automobile.)

MOTOR tire repairs are now being undertaken by the Clipper Pneumatic Tyre Co., Limited.

A MOTOR TRADE EMPLOYMENT AGENCY is the latest development in the automobile world.

"F. H. P." is referred to the work on "Horseless Vehicles" by Mr. Gardner D. Hiscox, recently published by Sampson Low, Marston and Co., London.

ALL the new type of two-cylinder Napier motor-carriages for 1901 will be fitted with a 9 h.p. motor in place of the 8 h.p. engine as in the past.

THE City Editor of the *Westminster Gazette* acknowledges that the motor-car industry "is advancing by leaps and bounds, and gives promise of a magnificent future."

MR. HUGH MOFFAT, of Bournbrook, Birmingham, has just issued a little waistcoat-pocket card giving a list of spare parts which should be carried by motor-cyclists, and a number of useful hints to riders of motor trikes.

LAST week we referred to the consideration now being given by the Home Secretary to the speed of motors on the road, and on Wednesday of this week one of our cycling contemporaries gave some "information published exclusively by us" as follows—"I have the best authority for stating that the Home Office is at present considering the whole question of the speed of motors on the road."

THE leading feature of the divisional manoeuvres of the Austrian military authorities just concluded was the experiments made with motor-vehicles. It is stated that as a result of the trials the authorities are fully convinced that for all purposes of haulage the motor-car is essential to the equipment of an army. The conditions were made as trying as possible. The cars were put to work through level country churned into mud by the operating armies, and among the abrupt steep inclines in the lower spurs of the Carpathian Mountains.

ELECTRIC TROLLEY OMNIBUSES.

At a meeting of Section G of the British Association, on Monday, Mr. J. G. W. Aldridge read a paper on the automobile for electric street traction. He pointed to the difficulties presented to the provision of electric traction, particularly in crowded localities, one of the chief of which, he said, was that of expense. In the adoption of the system he advocated he claimed as advantages that no permanent way was required, overhead equipment was reduced to a minimum, the electric motor-cars had no accumulators to carry, and the system was worked from the same generating station and feeders as the tramway system. The first cost was, therefore, enormously reduced, and the motor-cars or omnibuses might run through any streets which allowed vehicular traffic. This system provided for a service of electric motor-vehicles deriving power from a pair of trolley wires supported on short brackets along one side of the road. On these wires ran a two-wheel trolley containing a small electric motor for its own propulsion, the whole being connected to the omnibus by a flexible cable attached to a pole on the roof, devices being provided for keep-

ing the cable sufficiently taut and to obviate any risk of derailing the trolley. Continuous current at 500 volts was supplied to the omnibus motor via the trolley wheels and flexible cable. The system dealt with is that of M. Lombard-Gérin, who has established an experimental line in the Vincennes Annex of the Paris Exhibition.

THE *Poids Légers* competition will commence in Paris on Monday, the 17th inst. So far seven entries have been received.

A SERVICE of steam omnibuses is about to be started between Genoa and Piacenza, Italy. The vehicles, which will accommodate twenty-five persons, are being supplied by Messrs. De Dion, Bouton, and Co., of Puteaux, France.

La France Automobile states that a Koch heavy oil car is now being used by the French military authorities for the conveyance between Vincennes and Champ de Mars of the pigeons used in the pigeon-post service.

ACCORDING to the *New York Herald*, Mr. I. A. Lyon and Mr. Luis de Onativia have started from Paris on a new 16 h.p. Panhard car for a trip via Dieppe, Newhaven, Brighton, Henley, Leamington, to the North of England. At Liverpool the car will be shipped to America.

THE promoters of the *Inter-Ocean* motor-vehicle tournament, which is to be held at Chicago from the 18th to the 22nd inst., are endeavouring to secure a race between Mr. A. C. Bostwick and Mr. W. K. Vanderbilt, Jun. As both these gentlemen are owners of European built high-powered cars, the race, should it take place, should prove an exciting event.

RESISTANCE OF ROAD VEHICLES TO TRACTION.*

BY PROFESSOR HELE-SHAW.

ABOUT the time of the general introduction of railways considerable attention was directed to the nature of the resistances encountered by vehicles upon the common road, and the researches of Correze, Edgeworth, Coriolis, Morin, Tredgold, Dupuit, and others must be regarded as having thrown considerable light upon the subject. From time to time recently others have done work in this direction, but there is no doubt that the attention directed to traction on railways has thrown the scientific investigation of the subject of common roads almost entirely into the background. During the last few years, however, it has been realised that there was a great field for the development of traction, and particularly by mechanical means upon the common roads, and the improvement which has been quietly taking place in the construction and maintenance of roads is a feature of national importance. Not only is the condition of the pavements in the cities and towns much improved, but in out-of-the-way districts, such as in the hilly parts of Cumberland and Westmorland, the use of steam rollers by the County Councils has effected vast improvement in the state of the roads. Various causes have contributed to this result, but it is worthy of notice that whereas when the coaching days became comparatively a thing of the past the roads fell into neglect, so now the increasing number of cyclists and tourists who visit country places are an appreciable factor worthy of the consideration and encouragement by the local authorities. The recent remarkable and growing development of motor-vehicles with a legal limit of speed as high as twelve miles an hour, and the generally increased speeds of tram-cars in cities owing to the introduction of electricity and steam, give some reason for thinking the general rate of speed on common roads may reach, or even exceed, the present legal limit applying to motor-vehicles. As showing the mechanical possibilities in this direction, it may be pointed out that quite recently in France between forty and fifty miles an hour has been safely maintained for more than 300 miles upon the common road. Such a speed—or anything approaching to it—would not be allowed in this country, but the fact remains that it is possible with safety. With heavy traffic the legal limit for a self-propelled wagon of about two tons tare, capable of carrying several tons, is no less than eight miles an hour, and the heaviest traffic with a tare limit of vehicle of three tons, probably carrying a load of eight or ten more, is as high as five miles an hour.

These facts, and the introduction generally of mechanical propulsion, point to the necessity of having a fairly complete knowledge of the resistance of common roads of various kinds upon different classes of vehicles moving at different speeds. In the brief historical account given by the author of what has hitherto been done in this direction it will be seen that the experimental means of traction has without exception—as far as the author is aware—been limited to traction by horses; and as at any rate the earlier experiments were made with the view of horse traction, only two speeds were taken into account, viz., walking and trotting. Considering the variation in speed of horses under these two conditions, these terms cannot be said to express anything very definite, and certainly afford no guidance whatever as to the resistance of self-propelled vehicles at various speeds. Again, in recent years large sections of cities have been paved with asphalt and wood, while the laying of setts or stone pavements has undergone considerable modification, which is readily seen by an examination of a modern street and one of ten or fifteen years ago. Another modern development is the introduction of solid indiarubber and pneumatic tires, which were at first regarded merely as a luxury, but have now proved to be an important factor in the life of the vehicle, as well as of its resistance, this being so much the case that efforts have from time to time been made to introduce the use of indiarubber tires upon traction engines.

Beyond the foregoing points, which have not been brought

* Paper read before Section G of the British Association at Bradford.

under investigation in connection with the resistance of vehicles, no attempt appears to have been made to ascertain the extent to which the various factors of resistance relatively effect the whole result. Now it is evident that as the higher speeds are used, and the weights are increased, vibration and shock become more and more important; thus the resistance due to the rim of the wheel, and the ways in which it can be met by mechanical contrivances, must be regarded as quite a different problem from that of the springs attached to the body of vehicles, and some distinction must be made between the resistances as effected by each of the foregoing.

Enough has been said to show that there is not only matter for an inquiry which would be welcomed by makers of road vehicles, especially of self-propelled road vehicles, but that such an investigation, if it is to be of any real value, must be thorough, and requires not only some expenditure of money, but cannot well be undertaken by any single individual. The great interest which was excited by the paper read by Mr. Thornycroft at the last meeting at Dover of the British Association, and the previous communications which have passed between the author and the president of this section, who is himself a high authority upon the question of roads, have led to this matter being brought forward with the idea of forming a committee of the British Association for the investigation of road resistance.

In order to facilitate the work of the committee a summary of previous investigations in this subject has been prepared, which can be laid before the members, if it is formed. Some preliminary experiments have also been made with a view to obtaining some idea of the nature of the apparatus thus required, and the amount of expense likely to be entailed.

Preliminary Experiments.—Allusion has been made to the fact that all the previous experiments have been performed by means of the traction of horses; it seemed with the introduction of powerful motor-cars it might be able to pull steadily any vehicle at any required speed. This idea really forms the chief feature of the proposed experiments, as it is evident that if one motor-car is not sufficient two or more could be harnessed

to the vehicle which is to be drawn. In order to ascertain how far this idea was practicable Mr. J. A. Holder, of Birmingham, who owns a 12 h.p. Daimler car, was kind enough to visit Liverpool, and on Tuesday, Wednesday, and Thursday, July 17th, 18th, and 19th, a series of experiments, in which the author was assisted by two former students, Mr. Humfrey, B.Sc., and Mr. Cormack, B.Sc., were made, Mr. Holder's car towing the author's New Orleans voiturette. These experiments took place over roads of asphalt, wood, setts, and macadam in the neighbourhood of Liverpool, both level and up the steepest gradients which could be found, viz., Everton Brow. It will not serve any useful purpose at present to give the detailed results of these experiments, as they were obviously incomplete, and pointed to the absolute necessity of more elaborate apparatus of a self-recording nature; but it may be of interest to explain the apparatus actually employed, so as to indicate what will be required to insure satisfactory results.

The apparatus consists of two parts: (1) a dynamometer and (2) a speed indicator:

Dynamometer.—This consisted of an ordinary spring balance, the back of which was riveted to a cylinder of a small steam engine which acted as a dashpot. The ports of the steam cylinder were closed up, and a small hole drilled into the piston was found quite sufficient when the cylinder was filled with oil to check the free oscillations of the spring.

Speed Indicator.—The speed indicator was a Schaffer and Budenburg tachometer to which a temporary wooden wheel was attached, and a special dial was made, so that instead of indicating revolutions per minute the miles per hour at which the vehicle was travelling were at once made visible. The mode of conducting the experiments is shown by a photograph. A rope about 20ft. long was attached to the voiturette and connected with the dynamometer, the dial of which an observer was able to read. At the same time a second observer called out the actual speed of the vehicle at that instant and the nature of the road which was being passed over, which were recorded by the first observer in his note-book, together with the pull on the dynamometer.

The net result of the experiments showed that even on apparently the smoothest road the variation in the pull was so considerable that nothing but appliances which would record autographically both the pull and velocity at the same instant and indicate also the distance travelled, so as to identify the exact piece of road corresponding to the record, would be of any value. Moreover, it was evident that some autographic record of the nature of the road as well as some instrument for recording the vibration of the vehicle which was being towed were necessary in order to form some estimate of the effect of vibration upon the resistance. With such appliances the pull on wagons, lorries, ordinary vehicles with iron rims, pneumatic and indiarubber tires, could be investigated for any speed, and it is not too much to hope that some definite idea of the laws concerning traction might be found, with the effect of springs, tires, and the surface of the road taken into account.

DR. CHURCH'S STEAM CAR, BUILT ABOUT 1832.

FURIOUS DRIVING CASES.

At the Yarmouth Police Court last week, Mr. Edward E. Lackenby was summoned for furiously driving a motor-car. Sergeant Mason said that on the previous Friday he saw defendant driving a motor-car at the rate of ten or twelve miles an hour along the Parade. Defendant said he could not remember being on the Drive at the time, but Police-constable Fish also proved he was there. Defendant said he did not think he was driving too fast, and in

reply to Mr. De Caux said he drove his car at eight or nine miles an hour. He had been passed by every other motor-car on the Drive, and been laughed at for being so slow because he was careful. Mr. de Caux said that on the Drive a good many motor-cars and bicycles went a good deal too fast, and they often came round a corner on the wrong side of the road, which was very dangerous. Defendant was fined 20s., including costs.

CHARLES ALBERT CLARK, cutlery manufacturer, of Sheffield, has been summoned for driving a light locomotive on the highway in the parish of Skipsea (Yorkshire), on the 19th August, at a speed which was calculated to endanger the safety of the public. P.C. Bell deposed that on Sunday afternoon, the 19th August, at 3.45, he was on duty on the Bridlington-road, Skipsea, when he met the defendant driving a motor-cycle at a furious rate. He was going at the rate of about 20 miles an hour. He had another man with him. The weather was foggy, and witness could only see the defendant at a distance of 150 yards. He was then coming down a hill, and witness had the greatest difficulty in getting out of the way. Witness followed him to Hornsea, and told him he should report him for furiously driving. Defendant pleaded that he was only going 13 to 14 miles an hour. A fine of £1 and costs was imposed.

At Porth Police Court last week, William James Gunning, motor-car driver in the employ of Mr. F. Gould, landlord of the Brigend Hotel, Pentre, and the Osborne Hotel, Barry, was summoned for furiously driving a motor-car down Tynewydd Hill, near Treallaw. Mr. James Phillips, solicitor, Pontypridd, who defended, observed that in cross-examination Police-constable Harrel said that the passengers had not complained to him of it; neither did he see any persons running away from the car.—Mr. Phillips said that the car was only registered to travel twelve miles an hour, and at the time in question could not have gone faster than nine miles an hour. But his point was that there was no evidence to show that the car on the night in question had been

dangerous to life and limb. Not one of the passengers had complained, and the constable's evidence as to it being dangerous, he submitted, could not be accepted. He argued that if a man was on the pavement, and the car travelling over the road, even at a rate of thirty or a hundred miles an hour, the driver was not liable to prosecution.—Defendant said he had been driving motor-cars for five years in London, and had built this car.—The Bench, after a lengthy consultation, dismissed the case.

At Douglas on Saturday last, John Lewis, driver of a motor-car for the Isle of Man Cycle Company, was charged with travelling along the Promenade at a speed which endangered the public. Evidence was given that the car was going at the rate of ten miles an hour, and that many people had to hurry out of the way. The defence tried to show that the car went but a little faster than the trams and 'buses, out of the way of which people had frequently to hurry, and that defendant was justified in travelling at 40 miles an hour if the road was clear. Mr. Hutchinson, J.P., said that drivers of all sorts should remember they had as much right to get out of the way of foot passengers as foot passengers had to get out of their way. Lewis was fined 10s. and costs.

At Llanrwst, on Monday, Mr. William Geipel, of Blackheath, London, was summoned for furiously driving a motor-car on the 25th August. Superintendent Jones said about 7.35 p.m. on the night in question he saw the defendant, who was accompanied by a lady and a little boy, coming at such a furious rate down Station-road that he (witness) thought he had lost control of the machine. He held his hand up, and defendant stopped within four yards. The streets were crowded at the time, and the defendant was going as fast as a horse could gallop. Defendant denied that he was travelling at an unusual rate, and as he did not want to be summoned offered to pay any amount witness liked to a public institution he liked to name. The defendant, who did not appear, was fined £5 and costs.

OBSTRUCTION BY MOTOR-CARS.

At Bow Street Police Court last week, Mr. Archibald Ford, of 2, Shaftesbury Avenue, was summoned, before Mr. Marsham, for causing an obstruction by a motor-car. Police-constable 102A stated that the defendant left a motor-car standing in the roadway at Charing Cross from 3.35 to 4 in the afternoon. It caused great obstruction to the traffic, and eventually a 'bus ran into it. The defendant said he left the car standing in the street while he went into an office to see his solicitor. He expected to be gone about four minutes, but time passed quickly, and he was absent altogether about twenty-five minutes. It was only a small car, holding three persons, and he did not think it could have caused any obstruction. The 'bus that ran into it did damage to the extent of about £5, and possibly there would be county court proceedings. Mr. Marsham: Of course no one had a right to run into your car, but you were causing an obstruction, and must pay a fine of 2s. 6d. and 2s. costs.

At the same court, Mr. Selwyn F. Edge, of Tavistock Chambers, Hart Street, W.C., was summoned for committing a similar offence. Mr. T. W. Staplee Firth appeared for the defendant. Police-constable 112D stated that on the afternoon of the 25th ult. he was on duty at the corner of Hart Street and Museum Street. At twenty-five minutes to two o'clock the defendant drew up at Tavistock Chambers, Hart Street, in a motor-car, which he left outside while he went upstairs. The defendant allowed the car to remain in the roadway till twenty minutes past three o'clock. During that time fifty or sixty persons stood round the car, and the vehicular traffic was greatly obstructed. There were three lines of vehicular traffic. When the defendant came out, and witness told him the car had been staying in the street an hour and three-quarters, he said, "Do you mean to say it cannot remain there as long as I like?" In reply to Mr. Firth, witness said a furniture van stood near the motor-car, but the men in charge were engaged in loading or unloading. Mr. Firth argued that the mere opinion of a constable as to an obstruction having been caused was not sufficient to warrant a conviction. He submitted that some private person who felt aggrieved should be called to complete the case, and in support of his contention cited the case in which a newspaper boy was summoned for shouting his papers late at night to the annoyance of the public. He was fined, but upon the case being taken to a Divisional Court the conviction was quashed on the ground that no private individual had been called to prove annoyance. Mr. Marsham said that case had nothing to do with obstruction, and there was nothing in the point raised by Mr. Firth. If an obstruction was caused to traffic in London the police had a perfect right to take proceedings. The defendant was called, and said that on the afternoon in question he was going to take his wife out on a motor-car. While he was waiting for her to dress a heavy storm came on, and the motor-car remained outside until the rain abated, but no obstruction was caused, and it was untrue to say that the car was surrounded by fifty or sixty persons. Mr. Jarrott, a friend of the defendant, agreed that no obstruction was caused, and said that not more than two persons stood looking at the car at any one time. Mr. Marsham said he had no doubt the defendant let the motor-car stand in the road longer than he would have done if it had not rained, and only called upon him to pay the cost of the summons, 2s. A few minutes afterwards Mr. Firth returned to the court and said he wished to take the case to a Divisional Court, as there was no evidence as to obstruction. Mr. Marsham: It is absurd to say there was no evidence. The constable distinctly said an obstruction was caused. Mr. Firth: And I called three witnesses who said there was no obstruction. Mr. Marsham: The constable proved an affirmative. Your witnesses tried to prove a negative, which, of course, is a very different thing. Mr.

Firth: Will you grant me a special case? Mr. Marsham: Certainly not. Mr. Firth: I would rather that you fine him, so that I may take the case to a higher court. Mr. Marsham: If you like I will fine your client, but it will not do him any good. Mr. Firth: Then I must leave it where it is, but I must say the police treat motor-car drivers as though they were all rascals, and they are too readily upheld by the courts.

FATAL ACCIDENT AT ABERDARE.

At Aberdare Police Court, on Tuesday, William Howard and George Ison, the driver and conductor of a motor-car at Mountain Ash, were charged with having killed a child, aged two years and nine months, at Abercynon on Monday last. Mr. J. W. Evans, Aberdare, defended. Mr. George Blacker said he was sitting in his house when he heard a motor-car come down the street. He heard it grinding against the kerbstone, and ran out and saw the deceased child between the wheels. He saw the hind-wheel pass over the child. He shouted to the driver to stop, and he did so. The child had one leg crushed and the other practically off. It was taken to the Cottage Hospital, and died that evening. Ison was driving. Cross-examined: Witness went out fearing his own child was about. There was a cart on the road opposite, and the horse's forefeet were in the gutter opposite, and the cart somehow slewed to the road. There was some room between the tail of the cart and the motor.

Mr. William Smith, who drove the cart, said the motor-car was coming towards him, and when some five yards away his horse shied suddenly to the gutter and slewed the cart somewhat out into the road. Defendants then swerved. He did not see the child until it was run over. Police-constable Tucker, Matthewston, said that he found by the marks on the kerb that the cart had ground against the kerb for 28ft. The width of the road at the point the spots of blood were was 23ft. Cross-examined: He could not say less than that the child had been drawn to the spot. It was picked up from the middle of the road.

Mr. J. W. Evans made an eloquent appeal to the bench not to commit the defendants. All the evidence showed that it was a pure accident. There was no evidence whatever of negligence. The Bench, however, decided to send the case for trial, but admitted both defendants to bail on their own recognisances.

THE MOTOR TRACTION COMPANY.

THE second ordinary general meeting was held at Cannon Street Hotel, London, last week. Lieutenant-Colonel C. E. Macdonald, who presided, said that since the present board took office they had had to encounter many difficulties and discouragements, but he believed that they would succeed in bringing the company to a successful and dividend-earning stage. He thought that the shareholders would agree with the directors in refusing to make any large capital outlay on motor-omnibuses until a more perfect type of vehicle than those hitherto built had been evolved. The two petrol omnibuses now running between Oxford Circus and Kennington Gate, and which were built under the direction of the previous board, had been put through a very extended trial. By the new licence granted by the vendors the company obtained the right to manufacture not omnibuses only, but any kind of motor-carriage under the patents of the licensors. Seeing that some considerable time must elapse before the omnibus business could be worked on any large scale, and being convinced that there was a large business to be done in the manufacture and sale of ordinary motor-carriages, the board had determined to take steps to develop this part of the business. Another consideration which had influenced them in coming to this decision was that when the company possessed a proper manufacturing plant they would be able to build their own omnibuses and thus save a great deal of money in the initial cost. With the object he had mentioned in view, the company had secured the business and premises of Mr. Alex. Mackenzie, of Lambeth. The board had made what they considered a satisfactory arrangement for the manufacturing rights and control by this company of an invention in motor engines, patented by Major Holden. The engine was remarkable for its lightness, simplicity, and freedom from vibration, and, if the expectations formed after a trial of the models which had been in use for some time should be fully borne out when the engine was constructed on a larger scale, it was believed that a great improvement on existing motors would have been obtained. Turning to the balance-sheet, he said that the figure of £210,000 appearing on the assets side of the earlier balance-sheet under the heading "licences and patents," was now reduced to £50,000, representing the sum by which the purchase price in cash and shares for the licences and patents was reduced. Of the authorised capital of £420,000 rather less than £140,000 had been issued, and of this amount £5 per share, representing about £68,000, had at the date of the present balance-sheet been called up. The call since made brought in about £35,000. He concluded by moving the adoption of the report. Lieutenant-Colonel C. M. Davidson, who seconded the motion, said that when the company built their own omnibuses they should be able to run them at a profit. A discussion followed, in the course of which considerable dissatisfaction was expressed with the company's position, and Major-General Fellows suggested that it should be wound up. He had no faith that the business would prove successful. Mr. Heath moved an amendment to adjourn the meeting for a month, to enable certain shareholders, who were ruled out of order on rising to speak, on the ground that they had not paid the last call, to pay the call should they see fit. This was duly seconded, and on a show of hands was negatived by a majority of one. The motion for the adoption of the report was afterwards carried by a small majority.

THE Motor-Car Journal.

VOL. II.]

LONDON, SATURDAY, SEPTEMBER 22, 1900.

[No. 81.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

THE Maidenhead Corporation decided on Wednesday evening that the tolls for Maidenhead bridge should be lowered to 6d. for motor-cars and to 3d. for tricycles for one day, however many times the bridge might be used. Alderman Cox said that motorists would no doubt consider that they were very fairly dealt with by Maidenhead, seeing that the toll for Cookham Bridge was 1s. 6d. for the first time, and 9d. each subsequent time, while at the west end of the county one

authority charged 4s. 6d. for each motor-car. Councillor Upton said he had no doubt that the reduction would result in benefit to Maidenhead and its trade. The change will come into operation after October 31st. Excessive tolls should be resisted wherever possible, and certainly should have full publicity. No doubt the many letters that have appeared on the subject of the toll over Maidenhead bridge have had much to do with this reduction.

Porlock Hill Again.

So many rumours have been in circulation with regard to the ascent of Porlock Hill by the Napier car that an authoritative statement from Mr. Edge should now settle up some little points about which contradictory things have been said. It appears that the motorist and a local gentleman were casually discussing the possibility of motor-cars ascending the hill. Mr. Edge maintained that there was no difficulty providing the car was geared low enough, and made a bet of £50—not £20 or £1,000—that his car would go up the hill. This was done at an average speed of 12 miles per hour. "Of course," says Mr. Edge, "a much lower powered car would also have gone up easily enough, but very, very slowly, and, curiously enough, the thing that impressed everybody there was not the fact of its climbing the hill, but the fact of its going up faster than they could run up, or drag a coach up, or even gallop a horse from top to bottom; that is to say, a motor-car went from the bottom to the top of the hill in faster time than any other method of travelling on the road could do. And then, again, you must remember that a car of this sort is an ideal car to drive, for the simple reason that whilst it develops a big h.p. when run at 750 revolutions a minute, one can go along at 10 or 12 miles an hour with the engine running at 250 revolutions per minute. The result of this is that you get very little wear of the car."

Another Car Goes Up.

CONFIRMATION of Mr. Edge's statement as to the ability of a lower-powered car than his 16 h.p. Napier being able to ascend the hill comes this week. On Saturday Rouse, one of Messrs. Hewetson's drivers, took a Benz Ideal Victoria to Mr. H. Hickley, of the Electrical Works, Taunton. Mr. Hickley met the car at Bath and went on with it to Castle Cary, arriving

there eight hours after it had left London. On Monday Mr. Hickley and the driver left Castle Cary at 10.30 a.m. for Taunton, via Ilminster. At 3.45 p.m. they left Taunton for a run up Porlock Hill, which the car successfully negotiated at 6 p.m. In some places the road had inches of loose material, into which the wheels sank deeply.

Passing Horses.

IN another column will be found a report of the inquiry into the circumstances of the death of the gentleman who fell from a coach at Cheltenham recently. It appears that the driver of the coach requested a passing motorist to stop. He did as desired, but the vibration of the car frightened the horses, one of which bolted, and all the passengers were thrown. Captain Hunt, the owner of the coach, said that had he been driving he would have driven past the motor-car without stopping it, so as to get away from the noise as soon as possible. He thought no one was to blame. There is no doubt that the best plan is to drive right past animals whose temper is unknown or uncertain.

An Experience on the Brighton Road.

THIS was demonstrated during the course of a drive to Brighton on Saturday. Turning a corner we came suddenly upon a coach and four. A gentleman, apparently the owner, jumped off the coach and put up his hand. We immediately slowed down, and as the horses did not appear restless we continued travelling slowly until we got past the them, when we stopped. The gentleman came up to us and remonstrated for not stopping immediately when he raised his hand. Our contention was that had we done so we should most assuredly have frightened the horses. He informed us that one horse had been giving him trouble all the morning, and he was extremely nervous about that particular horse, otherwise he would not have troubled us. Continuing our journey, when passing over Clayton Hill we heard the well-known sound of a motor horn behind us, and saw coming towards us Count Seilern's cream-coloured 16 h.p. Panhard. On it as passengers were Mr. Cheel and a lady. Meeting Mr. Cheel at the Hotel Metropole afterwards, he mentioned he had met the same coach which we had passed, but being near a lane they had turned aside and stopped the motor. The gentleman got off the coach and thanked the occupants for turning aside as they had done.

Taken at Luton.

THE group on another page shows some of the cars and motor-cycles participating in the English Motor Club's run at Luton on the 8th inst. They were drawing up for the start to Bedford, and in the group are the faces of several well known motorists. To the left of the photo Mr. Leonard is standing by his motor-bicycle, with Mr. G. L. Rendell on his left. To the rear of the latter, with both hands gripping the handle-bar, is Mr. M. Moyle on his motor-tricycle, and a little behind is Mr. T. Maltby, jun. On the right Mr. and Mrs. Edge are in full view, and to their rear is Mr. F. F. Wellington, with Mr.

E. W. Hart peering over his shoulder, the latter gentleman being faced by Mr. Holtzafel. Immediately in the foreground is a brother of Mr. E. W. Hart, ready to act as pilot on the way to Bedford.

A Run to Wendover.

ON Saturday, the 22nd inst., the English Motor Club will have a run to Wendover via Uxbridge and Amersham. As the trip is a somewhat short one, the distance being only thirty-five miles, the motorists will take their own time in getting to the destination, where dinner will be served at the Red Lion Hotel at 7.30 p.m. On Sunday a run to Thame via Aylesbury has been arranged, with luncheon at the Spread Eagle Hotel. Then via High Wycombe, Great Marlow, and Maidenhead, the party will return, via Colnbrook, to town, the whole distance of the day's run being about sixty-eight miles. The road to Wendover is a particularly pretty one and the view of the Chiltern Hills very fine. It is one which is not generally known to motorists and on that account alone will have a particular charm. The Club, as before, will welcome most cordially any motorists, not being members of the Club, who would like to take part in the run, and further particulars can be obtained either from Mr. F. W. Baily, hon. sec., at 94, Oakfield Road, Penge, or the Chairman of the Runs Committee of the Club, Mr. Charles Jarrott, 14, Regent Street, S.W.

A Lady Automobilist.

ALTHOUGH lady automobilists are not yet so numerous in this country as in France, their number is, we are glad to say, steadily increasing. Our illustration shows Mrs. Thynne, of Horley, at the helm of a Marshall car, in which she may be frequently seen driving about in the district. Mrs.

Thynne is the daughter of Dr. J. Muter, the Public Analyst for Lambeth, to whom the car belongs, and has become quite an adept *chauffeuse*.

To Waterloo by Motor-Car.

SHADE of the Iron Duke! The latest thing from Brussels is the organisation of trips to Waterloo and over the historic battlefield by motor-car. And why not? For by such means the whole area of the great conflict may be traversed and every point of interest seen within a reasonable time. Hitherto it has been impossible for visitors to adequately inspect the field of Waterloo in any reasonable time from the tourist's point of view. But the automobile has changed that state of things, and the development should suggest imitation in other historic districts—such as Shakespeare's country, the land of the Lake poets, etc.

Automobiles at the French Manœuvres.

ALTHOUGH the troops have up to the present been manœuvring some distance from the town, the distance varying from twenty to sixty kilomètres, the fact that General Brugère, Generalissimo of the French army and director of the manœuvres, established his headquarters at Chartres caused a continual coming and going of officers of the staff, aides-de-camp, and orderlies, on foot, on horseback, on cycles, and in automobiles. This last innovation has been the great feature of this year's French military manœuvres, and all day long the streets of the town have echoed with the puffing and the rattle of the vehicle of the future. There were automobiles of every kind, tricycles, two-seated, four-seated, and eight-seated carriages, driven by petroleum and electricity, and long lines of transport wagons, veritable trains, puffing slowly along, drawn by the Dion-Bouton and Scotte steam tractors. General Brugère boldly accepted the innovation and attended the manœuvres in a four-seated Panhard-Lavassor car. The rate at which he travelled certainly inspired awe. One saw a distant speck in the road three or four miles away, travelling in the midst of a cloud of dust. Five minutes later the speck took the form of a white painted automobile, which rushed by like a whirlwind. At the instant it passed, through the dust cloud the Generalissimo of the French army and his aide-de-camp were seen, their faces covered with black masks with glass-covered eyeholes, and a minute later, the vehicle, travelling at sixty kilomètres an hour, was again a speck in the distance. The automobile of the Generalissimo occasionally gave an illustration of the hare and the tortoise. One morning it passed the representative of the *Times* and the Paris correspondent of the *Daily Graphic* (to whom we are indebted for the foregoing) travelling like a meteor as usual, but five kilomètres further the steady trot of their horses enabled them to overtake General Brugère, whose mechanic was wrestling with a burst tire.

A Motor-Bicycle in Switzerland.

FOLLOWING on the reference to Mr. Joseph Pennell's feat in Switzerland by "Lollius" last week we now give the following details. Mr. Pennell set out on his trip from Paris. He went over the Juras to Andermatt and Lausanne and up the first portion of the Furka Pass. The second portion of the latter was traversed by carriage. The Furka pass is closed to motorists by the police authorities and so Mr. Pennell's ability to pedal stood him in good stead on that part of the ride. By means of his motor-bicycle he was able to do the whole trip in about half the time that would have been taken by an ordinary bicycle.

Police Ingenuity.

THE declarations of policemen in police courts have been so frequently discredited that various devices have been suggested to secure reliable confirmation as to their testimony. Stationing comrades at various points with stop-watches has not been a successful method, and the requisition of field glasses—a practice adopted at Yarmouth a year ago—has not been continued. Now it is suggested in France that cameras working on the biograph principle should be employed. The notion is ingenious, but will never be seriously considered by the police authorities of this country. We doubt whether it will do anything but raise a smile elsewhere.

Ladies' Motor Garments.

ON Saturday the *Daily Chronicle* gave a sketch of a lady's automobile cloak, and declared that the sportswoman who is up to date should learn to drive her own motor-car. Garbed correctly for the pastime she will be seen enveloped in a long coat made of a material that is absolutely impenetrable so far as dust is concerned. In colour it should be that of the roads, though a mouse-grey is found a good alternative. The coat sketched is of stone-hued automobile silk much strapped and stitched with silk to match. The tricorne hat is excessively

smart, and is one type of the genus "cocher." Fine beaver composes it, and the sole trimming it possesses is a flat band of silk round the crown threaded through a long iron buckle in the centre.

Lincoln and Automobiles.

AUTOMOBILISM is developing rapidly at Lincoln, and the Lincoln Motor-Bus Company has decided to build extensive premises to accommodate the expansion of business which is anticipated. In this expansion Mr. A. W. Goodall is playing an important part. Motor-cars wait every evening at the theatre exits, and during the football season teams and their supporters will be rapidly and comfortably carried to the outlying districts. A number of bus tops are now being built for the cars, and a spirit of enterprise marks the whole concern. Every facility is wisely offered to owners of horses to train them to regard automobiles with indifference, and the public is showing great interest in the whole development. We hear that a passenger on one of the company's cars has just won a £10 cheque offered by *Pearson's Weekly* in connection with a novel competition now running to advertise that journal.

Carriage Builders and Motor-Cars.

THE construction of automobiles by English carriage builders was one of the subjects discussed at the conference of the Carriage Builders' Institute, which opened at Dover on Tuesday. The president acknowledged that motor-cars had "come to stay," and, in reply to the suggestion that coach builders were not keeping abreast of the times in this line, said their capital was, as a general rule, fully invested. But, supposing firms had the money to spare, the difficulty was to know what class of motor to adopt. He thought engineers should construct the machinery and running gear, the body of the motor-car being built by their own trade.

From Brighton to Arundel.

FROM North Street, Brighton, to the Castle at Arundel in eighty minutes sounds a "tall order," but we did it, says a writer in *Brighton Society*. And at no part of the journey did they appear to be going at a dangerous speed. Something depends upon the class of carriage, and much depends upon the driver; and in these two particulars everything necessary is combined in Mr. H. Chapman and his magnificent Daimler-Hampton char-a-banc, which has recently taken up a position for hire on the Brighton front. The road to the Duke of Norfolk's famous castle is one of the prettiest in the pretty county of Sussex, but it is also one of the most trying for vehicular traffic; and the hilly character of the journey, affording such constant changes of scenery, is not rendered easier by the present wretched state of the roads, a condition to which the local authorities should give early and proper attention.

The Motor Racing Track.

THE idea of a motor racing track is not dead, although it has been rather unobtrusive of late. Mr. S. F. Edge has now given his view of the matter. He would like the track to be in the form of a road with gradual curves, so that the highest speed could be taken at those curves without throwing undue strain on the tires. Of course the great radius which Mr. Edge considers necessary is in itself an obstacle to the realisation of the project at present, but the heavy expense of the tires when used on the ordinary racing track will probably prevent track racing growing to any extent. At the Automobile Club's race meeting at the Crystal Palace a few months ago an object lesson on this point was given. A racing tricycle used up a set of tires inside an hour, owing to the tremendous scraping action that takes place in going round the curves.

The "Traveller."

ENTERPRISE seems one noteworthy feature of the *Traveller*, the new sixpenny weekly paper which is being published by the Newnes Company. We hear that it is about to despatch Mr. C. N. Williamson on a long journey through the whole of France and Spain. The tour will extend through the winter, and his adventures will appear every week in the *Traveller*. The interest of the matter to our readers consists in the fact that he will travel on a motor-car of English manufacture—the Royal International.

The "Royal International" Car.

This new car, of which an illustration is given herewith, can be fitted with either an 8, 10 or 12 h.p. engine, and shortly a 16 h.p. motor will be available. The engine is made in either tandem or twin cylinder form, with all the valves on the top, so as to render them easily accessible. Two Clarkson coolers and a semi-rotary pump are provided in connection with the cylinder-cooling water. The frame is built of channel steel, the motor being suspended on the top of the same, so keeping the belts well out of the wet, damp and dirt. The crank is

enclosed in an oil chamber, and all lubrication is automatic. Electric ignition is adopted, a useful feature being that the sparking plugs can be detached without upsetting the packing of the joint. Three forward speeds—from two to twenty-four miles per hour—and one reverse are available. The car is claimed by its makers, the International Motor-Car Company, to be almost entirely free from vibration, and to be able to mount hills on the first and second speeds, the occasions on which the third speed is necessary being extremely rare.

The Sunbeam Car.

THE latest addition to the list of cycle-making firms taking up the construction of motor cars is John Marston, Limited, of Wolverhampton. In the particulars sent us the makers state that they have endeavoured to produce a vehicle combining the elegance and comfort of a victoria, with a motor and mechanism easily accessible in all its parts. The motor, which is located in the fore part of the frame, is of 4 h.p., with water-cooled cylinder, the water constantly circulating from a tank through a cooler to the water jacket without the use of a pump. The ignition is electrical, a small lever, placed conveniently for the right hand, being provided for timing the spark. The motor is started by means of the usual detachable handle. The cylinder and main bearings are lubricated from a sight feed box fixed on the dashboard in front of the driver. The power of the motor is transmitted to the driving wheels by belts. Two speeds forward and one reverse are fitted, the changes of speed being effected by fast and loose pulleys acting on a second shaft.

and connected with the live axle of the driving wheels by two gear wheels enclosed in the differential gear box. Wheel or other steering is provided as desired, while the road wheels are of wood, 28in. diameter at the front and 36in. at the back, fitted with either solid rubber or pneumatic tires. Two powerful brakes, both acting direct on the driving wheels, are fitted: (1) a band brake operated by a pedal for ordinary use, and (2) an emergency hand-controlled brake acting direct on the driving wheel tires by means of special shoes. The weight of the car is between 9 and 10 cwt.

Scotch Caution (?)

SCOTCHMEN are credited with caution and much worldly wisdom. They never do things in a hurry, and are regarded as considerate persons. That may be true of the race, but it apparently belies the character of the Corporation of the city of Glasgow. During the present month this august body invited tenders for a motor dust-van. Sealed tenders had to be submitted four days later—a fine chance for manufacturers to submit designs and prices. With such a display of unnatural celerity we shall not be surprised to hear that the stable manager of the dust-cart department is looking forward to a long and happy life among his gee-gees.

Some Early Automobiles at the Paris Exhibition.

NOT the least interesting feature of the Paris Exhibition from the automobilists' point of view, is the display of historical motor-cars that is to be found in various parts of the great show. Visiting the Exhibition last week, we noticed in the French section a Bollée steam 'bus of 1873, and a steam tricycle built by Roger L'abbé de Montais in 1885; also a De Dion steam tricycle of 1885, a steam 'bus of Amedée Bollée of 1885, and the first De Dion petrol motor-tricycle. The air-cooled motor of the latter looks rather insignificant when compared with the engines with which the De Dion tricycles are equipped to-day. Close by, in the Austrian section, the Austrian Automobile Club exhibit, on the stand of Messrs. Jacob Lohner and Co., an historical petrol vehicle, built by Herr Siegfried Marius in Vienna in 1875. The vehicle has a turning fore-carriage steering gear, a single-cylinder engine, a single speed-belt transmission from engine shaft to driving axle, and no differential. In the German section, at the Vincennes Annexe to the Exhibition, is shown the first Benz petrol motor-tricycle, with a single-cylinder engine, the shaft of which is placed vertically, an arrangement which was probably adopted to make room for the large fly-wheel with which the engine is provided.

The Prince of Wales on a Steam-Car.

ON the opposite page we reproduce a photograph by M. Serpollet, which depicts H.R.H. the Prince of Wales and Major-General Sir S. Clark on the steam-car with which he has been touring from Homburg to Frankfort and other places in Germany. Mr. Gardner is at the helm. As we said last week, his Royal Highness has now been on motor-vehicles of nearly every description, and evidently appreciates his experiences. Both Mr. Gardner and M. Serpollet have pleasant recollections of their drives with the Prince, who gave each a pin in the form of a sword set with brilliants as a souvenir of his trips on their car.

Steam-Cars in England.

TALKING of steam-cars, an attempt is about to be made to extend a knowledge of their merits in this country, and Mr. W. M. Letts, late of the British Motor Coupé Company, has been appointed general selling agent in the United Kingdom for the Locomobile. The headquarters of the Locomobile Company of America in this country will be, as heretofore, in Sussex Place, South Kensington, and Mr. H. N. Searles, who won many friends among automobilists during the 1,000-mile Trial, will continue in charge of the dépôt,

which now presents a busy aspect. So large has the business prospect become that no one man could supervise the whole of the arrangements, hence Mr. Letts will probably find his time well occupied in appointing agents and generally developing the popularity of the Locomobile throughout Great Britain. When in America he was much struck with the usefulness of the steam-car, and this enthusiasm for that class of automobile will now have a particular outlet—the progress of which will be followed by all interested in the new form of locomotion on common roads.

Another Royal "Chauffeur."

THE Shah, it appears, will not be the only royal automobilist in Persia, for already one of the princes has followed the example of his sovereign and purchased a self-propelled vehicle. "This new adherent to the motor cause is," writes our Paris correspondent, "his Highness Ehtessam-es-Saltaneh, and in selecting a Koch heavy oil car the prince has shown excellent judgment, for petrol is hardly a common commodity in his native land, and the *chauffeur* dependent upon it would have rather a worrying time; and the Koch is such an excellent vehicle that the automobilist about to voyage in far-distant climes should never hesitate to take it in preference to the light oil car. From personal experience I can testify to the good running of the Koch car."

Motor-Cars for Traders.

TRADE journals are giving more and more attention to the utilisation of the automobile in connection with the delivery of goods and there is no doubt important progress is being made in that direction. Apart from the heavy traffic now conveyable by steam wagons there are many retail trades in which the motor-car can be adopted with economy and success. The great difficulty that modern tradesmen who have only two or three horses for delivery purposes have to contend against is the uncertainty of their delivery. One day their animals may have comparatively nothing to do, and another they may have exceptional loads and far more than any respectable horse can be burdened with. These periods of relaxation and excessive strain tell very hardly upon horses, and hence the adoption of the automobile will be a boon and a blessing to that section of the equine race engaged in the delivery of goods.

Excursions from Coventry.

THE Coventry and District Motor-Car Syndicate has arranged a number of local excursions, commenting on which a writer in a Midland journal says: It has long been a mystery why in a city which is so closely connected with motor-car enterprise so little has been done in making use of the new vehicle to serve the purposes of the public. I have long wondered that no service of cars was run between different points of the city, say between Hertford Street and Earlsdon. The expense would not be considerable; the convenience would be great. I was in Nottingham lately, and saw there a couple of motor-cars engaged in 'omnibus' work, and very fairly they seemed patronised. Nottingham is, of course, a busier place than Coventry, but there was no difficulty with the omnibus and other traffic, the cars being steered with great comfort and freedom from accident. The horses seemed perfectly accustomed to them. The running of a motor-car for public convenience through any district of Coventry would be a good advertisement for the horseless carriage, as well as a public convenience.

AT the Paris Exhibition Messrs. Arnot and Marot, of Paris, exhibit a rotary engine, which can be run by steam, compressed air, gas, petrol, etc. The engine has four cylinders, and when working with steam or compressed air there are claimed to be eight impulses per revolution, while with petrol there are four impulses. The two engines shown are both constructed as explosive engines, having flanges on the cylinders for air-cooling. The engines have no flywheel, and are claimed to be entirely vibrationless.

Royalty and Automobilmism.

H.R.H. THE PRINCE OF WALES AND MAJ.-GEN. SIR S. CLARK ON A SERPOLLET STEAM CAR, MR. GARDNER AT THE HELM.
(See opposite page.)

THE RUN OF THE MILITARY GUN CARRIAGE IN AMERICA.

IN our issue of August 11th last we referred to the attempt that was to be made to run from Fort Sheridan to Washington the automobile rapid-fire gun built by the Duryea Company for Major Highland, of the U.S. North-Western Military Academy at Highland Park, Ill. The trip proved unsuccessful, and as various incorrect accounts of the failure have been circulated in America, the following authentic account of the run, sent by Major Davidson to the *Horseless Age*, may not be without interest:—

"Some weeks ago I started from Fort Sheridan with a motor gun wagon to carry a message to General Miles at Washington. With the exception of two or three minor troubles, such as the loosening of nuts and the short-circuiting of batteries, we got along nicely to just this side of Hammond, Ind., when one of our rear tires exploded. I was using some inferior tires, but as I had ridden some thousands of miles through Central Illinois with them, I assumed they would carry me at least 100 miles further to La Porte, Ind., where I had contracted with the Preston Hose and Tire Company, of Everett, Mass., to have new tires for me. On sending a messenger ahead, I found, however, that they had failed to arrive. To make a long story short, I was compelled to wait there, camped in the sand hills for twenty-two days before we could get our tires, all manner of accidents having happened at the tire factory in the meantime. When we at last did receive them, having in the meantime ridden the carriage some twenty

miles on a flat tire to get into a better country, it began to rain. We pushed on, however, to La Porte, Ind., much of the way through heavy black mud, and as it continued to rain for seven days, I was compelled to postpone the trip on account of work at home. I wish to say, however, that the engine did not explode, nor did we have any serious trouble aside from our tires. I am, in fact, so confident the trip can be made that I am now planning to build another carriage and take a battery of two carriages with the message to Washington. This I hope to be able to do some time in October."

Mr. J. B. WALKER, editor of the *American Cosmopolitan Magazine*, has the distinction of being the first to ascend Pike's Peak (Colorado) in an automobile. He reached a height of 11,000ft. The roads were very bad. The return journey was like going down a toboggan chute, and was fearfully rapid work.

THE recent automobile race from Berlin to Aix-la-Chapelle is said to have resulted in the following loss of life:—A cow, two hogs, three sheep, sixteen dogs, and twenty-three chickens. A stone wall and a hay-cart were also injured. The enumerator of these casualties must have had the sense of exaggerated imagination in addition to arithmetical talents of a very patient order.

SOME horses attached to an omnibus took fright in the Kew Road, Richmond, the other evening. Bolting through the town they collided with a butcher's van and a mineral water cart. Not satisfied with that, they jumped on a brougham and overturned a fruiterer's van, finally mixing themselves up with a hansom cab. Needless to say, the local reporter ascribes their excited condition to the presence of a motor-car.

CORRESPONDENCE.

A SUGGESTED IRISH MOTOR-CAR TOUR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—It is to be hoped that the Automobile Club will arrange some great event for next year. The success of the 1,000-mile Trial was so unmistakable that manufacturers would probably be glad of another great scheme to further popularise the industry. Of course, I know that there was a lot of expense, but experience has probably justified every penny that was spent.

Could not an arrangement be made that London and southern members of the club should go to Liverpool—a city that was missed in the last itinerary—and there be joined by a Scotch and northern contingent? Such a display would be welcome in a place where motor-vehicles for heavy traffic have been so much to the fore. Thence to Holyhead and across to Dublin should begin an interesting tour through a country where motor traffic will be popular in the near future.

A visit to the manufacturing towns of the north of Ireland should certainly prove a paying as well as a pleasant trip for manufacturers engaged therein.

Liverpool, September 18th, 1900.

Yours truly,
NESTORIAN.

PRICE'S BRAKE BLOCKS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I should be glad if any of your readers who have had experience of the above would favour me with an opinion of their usefulness or otherwise. I understand that when properly fitted they will so brake the wheels as to prevent the car running backwards. If this is so, surely they would be a great boon to motorists, especially those running 6 h.p. vehicles, weighing a ton or more.

Sheffield, September 17th, 1900.

Yours truly,
NERVOUS.

MAGISTERIAL WISDOM.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR, I have been much exercised over two decisions of Mr. Marsham, reported in this week's *Motor-Car Journal*, and should be glad to hear further opinions from your readers as to their soundness.

I have never had any trouble about my horse and carriage standing any length of time outside my patients' houses. This winter I am contemplating using a motor-car, but if I am to be responsible for the idle curiosity of the casual lounge I shall have to reconsider my decision.

Stones End House, Southwark, S.E.

Yours truly,
J. L. JAQUET.

September 15th, 1900.

TIRE TROUBLES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I am having a great deal of trouble with the tires of my motor-quadracycle, which I received new last March, and I should feel much obliged if some of your readers could give me some hints or instructions which would help me, and perhaps others who may be similarly placed, out of their difficulties.

I have not had any punctures, nor any cuts which have required attention, but after running a few hundred miles, say six or thereabouts, the strips or bands which are fixed on the treads of the tires commence to loosen or peel at the edges, coming away from the tire proper, and from this time onwards they are continually giving trouble, first one place and then another coming loose. A few days ago I refixed a number of loose places on one cover whose united length was as much as five feet.

I have five outer covers for four wheels, and, although I ride very little, and have not done more than about 1,500 miles since I got the machine, yet I seem nearly always to have a cover either wanting or undergoing repair, generally the latter.

I adopt the following method of refixing, which has been suggested to me, viz:—Clean out all the loose places carefully with petrol; let dry. Coat with Dunlop solution both tire and

strip; leave half-an-hour. Apply another thin coat; leave ten minutes or so. Bind tightly with tape or wide elastic, and leave for twelve hours or so.

I should be glad to know whether such strips as are on my tires can be fixed in such a manner as to be permanent, so that the fixing will last as long as the strips themselves. If so, is it likely that the covers, the strips, or the rubber solution is wrong in some way, or have they been fixed carelessly or by a wrong method?

I should be very glad to know whether my own method is at fault, and in what way. The trouble I have with the tires spoils most of the pleasure I get from using the machine, and seems to make me wish that I could get covers with a very thick tread, without strips, and run them, with comparatively little trouble, until they are worn out, and then discard them.

September 14th, 1900.

Yours truly,

LINZEE.

EXPERIENCES IN WALES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—As I see you make mention in a recent issue of the penalty inflicted upon me by the Llanrwst magistrates for alleged furious driving, I am prompted to write you briefly as to the results of my experience during a recent motor tour in Wales.

Taking first the case above alluded to, I was fined £5 and costs for entering this small town or village, where there were no other vehicles in sight, at the rate of ten miles an hour. The policeman said he thought my car was beyond control, though he admitted subsequently that it was stopped dead within four yards from the time of his signal. He further swore that the speed was fifteen miles an hour. Yet I was within thirty yards of a sharp corner, and was not, therefore, likely to be driving furiously with passengers whose lives I valued. Further than that, drivers of Daimler motor-cars will understand me when I say that I was on the third speed with the engine unclutched on a level road, and that fifteen miles an hour, or any speed approaching that, was impossible.

I did no harm to anybody; I stopped when requested to do so, and offered to reduce my speed to local requirements in future, notwithstanding the provisions of the Road Locomotives Act, but without avail. Taffy had got hold of an English motor-car driver, and he meant to salt him. I was accordingly persecuted by the police in every possible way, and subsequently fined £5 by the venerable Nestors of Llanrwst.

I see in the same issue of your paper that you make mention of four other prosecutions for furious driving, the total fines for which amounted to 50s., or an average of 12s. 6d. each, against mine of £5. These four cases appeared in English courts. On another occasion my car was actually standing in the road when a coach drove up; the horses shied at the car, and shortly after returning to my hotel I was honoured with a call from the local policeman. My name was promptly taken down, and in the course of the evening I was informed that a terrible motor-car accident had occurred, and given all kinds of tragic details, amongst others that a coach had been run into by a motor-car running at sixty miles an hour, killing two horses, etc., etc. The horses were working the following day.

I could give other instances of the prejudice and ignorance with which I met during my few weeks' tour in Wales, and can confidently state that I had more trouble than I have had during the whole of my motoring experience in England. I venture to suggest, therefore, to any of my fellow motorists who contemplate a tour, that they should give these small Welsh towns a wide berth.

Let us hope that some day our Welsh friends will not put such difficulties in the way of motorists desiring to visit their lovely country.

Yours truly,

W. GEIPEL.

Cardigan House, Shooter's Hill Road, Blackheath, S.E.

September 17.

AT St. Neots (Hunts.) last week Mr. A. J. Wilson was fined £4 for driving a light locomotive at a pace exceeding twelve miles an hour.

THE COTTEREAU VOITURETTE.

ALTHOUGH Messrs. Panhard and Levassor and other builders of powerful cars in France report no falling off in the demand for the same, the call for light vehicles is growing enormously, and all over the country engineering firms are busily engaged on their production. Hardly a week passes now that particulars of some new two-seated car of French construction reaches us, the latest being the Cottereau, built by Messrs. Cottereau and Co., of Dijon, and of which a general view is given in Fig. 1. As will be seen, the vehicle has an attractive appearance: it has a frame constructed of tubular steel, spring suspended, at both front and rear, on the axles.

A leading feature in the car under notice is the engine. This is of the two-cylinder air-cooled type, the two cylinders being set V-fashion under a perforated bonnet in the fore part of the frame. The valve chambers are located on the top end of the cylinder, and are, like the cylinders, provided with extra large radiating fins. The cooling of the cylinder is claimed to be further assisted by making the valve boxes quite distinct from the explosion chambers, and also by a special regulator automatically acting on the admission pipe, allowing only the absolutely requisite amount of explosive mixture to pass through the inlet valve at each suction stroke of the pistons. The cylinders are 80mm. in diameter, and the stroke is 100mm. Running at a speed of 1,000 revolutions per minute, the engine develops 5 h.p. The ignition is electrical, while a carburettor of the Longuemare type is fitted. As far as the differential shaft the transmission mechanism is very much on the lines of that adopted in the Panhard cars. Three speeds forward and a reverse motion are available. The motor shaft carries at its outward end one-half of a friction clutch, the other portion of which is mounted on the end of the variable gear shaft, in line with the engine shaft. The variable gear consists of a train of spur wheels, any one of which can be made to mesh with corresponding pinions on a short parallel shaft which conveys the power by bevel gear to an intermediary shaft at right angles. The variable speed gear is enclosed in an aluminium oil-containing case fitted

with a detachable cover to give ready access to the gear. From the intermediary shaft the power is conveyed to the rear axle, which is provided with a differential gear by a single chain; this axle is also so mounted that it can be moved backwards or forwards within certain limits to allow of the regulation of the tension of the driving chain. A foot pedal actuates a hand brake on the transverse intermediary shaft, while a hand lever at the side actuates a similar brake on the differential axle. The exhaust silencer is of large dimensions and is located right in the rear of the frame. Steering is controlled by an inclined bar, on which the electric current interrupter is mounted. Wheels of the cycle

type are generally fitted, and these are shod with pneumatics. The little car, which can be fitted with a spider seat at the rear if desired, weighs, with petrol, etc., ready to start, about 6½ cwt. With its 5 h.p. engine it is claimed that the vehicle will mount any hill, and on the level attain a speed of 28 miles per hour.

MESSRS. EVANS AND Co., of Llan-gollen, are now stocking petroleum spirit.

ONE of the most recent additions to the ranks of medical automobilists is Dr. Broom, of Kirriemuir, N.B., who has lately acquired a Mors Petit Duc.

THE Chief Constable of King's Lynn has suggested that a limit of about eight miles an hour should be regarded as a reasonable speed for motor-cars in the town.

MORRISTOWN, New Jersey, has adopted an ordinance which provides that no conveyance "driven or propelled by power" shall be run in any of its streets at a speed greater than eight miles an hour, and that all such vehicles

shall be equipped with lights that can be seen 100 yards away at night, and with bells "which, when rung, may be heard 100 feet distant."

WE understand that the Automobile Association of Holland Park, W., is about to be amalgamated with the British and Colonial Motor-Car Company, Ltd., of 14, Baker Street, W., under the management of Mr. J. H. Adams, and that Mr. Frentzel's services will be retained as technical manager to the amalgamated concern. We also learn that the company, in addition to their show rooms at 14, Baker Street, W., are taking over the extensive premises at 17, Balderton Street, W., known as "Motoria" and now occupied by the Motor-Carriage Supply Company, Ltd.

FIG. 1.—THE COTTEREAU VOITURETTE.

FIG. 2.—PLAN OF COTTEREAU VOITURETTE.

THE KÜHLSTEIN ELECTRICAL CARRIAGE.

AN electrical carriage with seating accommodation for four or five persons, and which comprises some novel features, has lately been constructed by the Kühlstein Wagenbauanstalt, of Charlottenburg, Berlin. A general view is given in Fig. 1, while details of the steering and speed control gear are shown in Fig. 2. The rear axle is in two distinct parts, each

FIG. 1.—THE KÜHLSTEIN ELECTRICAL CARRIAGE.

driven through double-reduction spur-gearing by an Allgemeine Electricitäts electro-motor of from 2 to $2\frac{1}{2}$ h.p. In order to equalise the strain on the three bearings on the compound axle a stout stay of H section is fitted to and below it. The electrical energy is stored in two batteries of accumulators, weighing together 1,100lb., one being carried under the driver's seat and one in the chest at the rear of the car, the combined capacity

FIG. 2.—THE SPEED CONTROL GEAR.

being stated to be sufficient for a run of fifty kilometres on one charge at a speed of ten kilometres per hour. The principal feature of the car is to be found in the combination steering and controller switch handle (Fig. 2). The vertical standard of the steering lever, which is similar to that used on cycles, is so connected to the levers at its lower end that while able to rotate on its axis it can be pushed away from or drawn towards the driver. The steering standard works inside a hollow tube; the latter is connected up

to the controller switch in such a way that the driver can push forward the whole steering column, or draw it nearer to him without in any way interfering with the steering. The end of the column works in a rack. Three speeds forward are obtainable according to the distance the steering bar is pushed from the driver; the first two positions, in pulling the bar towards the conductor, give electrical brakes, while the third one gives a reverse motion. In addition to the electrical brakes there are band brakes on each of the rear-wheel hubs, controlled by a foot pedal. The makers claim that by the adoption of the device illustrated in Fig. 2 the control of the vehicle is rendered most simple.

MOTOR-CARS ON THE CONTINENT.

(From Our Own Correspondent.)

The Delivery Volturettes.

ON Monday last there commenced, under the auspices of the Automobile Club of France, a competition for delivery voiturettes, and throughout the week this contest has been in progress. A route of some fifty kilometres through the heart of Paris has been followed morning and evening daily by the competitors, each of whom has been required to transport at least 100 kilos. of goods. Eleven entries were received for the event, but only eight actually competed. Peugeot sent a couple of cars, and De Dion, Fernandez, Jeantaud, Corre, Forest-Gillet, and La Parisienne one each. The somewhat unusual sight of these little vehicles fitted with small van or lorry bodies has excited considerable attention on the Boulevards. I hope to give details of each competitor's daily performance next week.

An Incident of Le Bol d'Or.

IN connection with the recent twenty-four-hour race held on the Vincennes track for the famous Bol d'Or, and which was so unexpectedly won by Cordang, a curious incident has to be recorded. Almost immediately upon the completion of the first hour, and while the spectators were following with feverish interest the great struggle between Walters and Huret, the pacing petrol tandem of the latter took fire, and its riders had barely time to run the machine to the top of the banking ere it was a mass of flames. Placed as the cycle was, a stream of petrol ran across the track, and as the flames mounted higher and higher it was feared that this would take fire and so stop the passage of the racers. By a miracle, however, this did not happen, and after the tank had exploded like a miniature cannon, the flames subsided, and were finally extinguished with sand. It appears that a rag wrapped round the sparking plug was the direct cause of the fire.

In Madagascar.

ON page 185 of the *Journal* of May 12th last I referred to the proposed automobile services in Madagascar, and now it is announced from that island that the first self-propelled vehicle has made its initial run from Moramanga to Tananarive, a distance of 108 kilometres, or some $67\frac{1}{2}$ miles. The motor-car is making its appearance in so many out-of-the-way places that one learns of these new services without any of that feeling of astonishment which formerly took possession of one when making such a discovery. The organisers of these services must certainly be endowed with ample courage, for, generally speaking, a work of this description is no light undertaking.

Another Nice Meeting.

THE Committee of the Nice Automobile Club propose to organise during the month of February next a week of racing reserved for tourists, and during which the cups presented by MM. Lebaudy, de Barry, de Linsky, and Brunetta d'Usseaux will be put up for competition. This meet will be

quite independent of the historic Nice week, which will take place as usual, and for which entries are already commencing to arrive. For the Nice-Avignon-Nice event, Paul Chauchard, Mercédès, Stead, Giraud, and Pascal have sent in their names, and many others will shortly swell the list. The club committee have decided to create certificates, to be awarded to those mechanics who are able to fulfil certain conditions relating to their competency, their length of service, and their general conduct. This is an excellent idea, and should give rise to a feeling of emulation, at present rather lacking among the mechanician class.

The Trailing Car.

THE motor-tricyclist is so often desirous of mounting a passenger upon his machine, that the invention of Monsieur P. Pasquet, of Etampes (Seine-et-Oise) should secure a ready market. The ordinary trailing car offers no attractions, for the passenger there receives the full benefit of the exhaust, which, combined with either the mud of wet roads or the dust of dry, renders his position disagreeable in the extreme. One has only to stand at the Porte Maillot on a Sunday evening and witness the return to Paris of scores of *chauffeurs*, each towing a friend seated in a trailing car, to appreciate the doubtful pleasures of this form of automobilism. Seated almost upon the ground itself, these begrimed motorists present the most miserable of appearances, and one is apt to wonder whether it is possible to find any pleasure in such a method of travelling. M. Pasquet's trailer, on the contrary, places its occupant well out of this dirt, and as he is seated conveniently near to the conductor, it is possible to carry on a conversation without indulging in the shouting inseparable from the use of the ordinary trailer. This new attachment is provided with a single wheel, placed at the extremity of a triangular frame. The method of attachment to the cycle frame permits the trailer to ride easily over the inequalities of road surface, and allows of corners being turned with ease and safety.

The Austrian Hill-Climbing Race.

A GREAT success has been scored by the Austrian Automobile Club with a hill-climbing competition over the well-known Schottvien-Semmering route, for not only were the entries fairly representative, but the racing also was keenly contested. Although the difference in altitude shows but an average gradient of 4 per cent. over the entire course, the rise is actually very severe in places, and the route throughout extremely trying. A French representative, in the person of Marcellin, figured in the category reserved for motor-cyclists, but only secured second place, his vanquisher being Dietrich, whose time was 75½sec. faster. A meritorious performance was achieved by Dr. V. Stern in the tourists' class, as his time of 16min. 57sec. was one of the best made in any category. The official returns are as follows:—*Motor-cycles*.—1, Dietrich, in 14min. 38½sec.; 2, Marcellin, in 15min. 54½sec.; 3, Mandl, in 16min. 43½sec.; 4, Warchalowsky, in 22min. 14sec. *Voiturettes*.—1, Stary, in 22min. 49½sec.; 2, Spitz, in 22min. 53sec.; 3, Risch, in 28min. 5sec.; 4, Jelinek, in 29min. 40½sec.; 5, Weiser, in 49min. 1½sec. *Electric Cars*.—1, Langlais, in 22min. 27½sec. Theyer and Porsche abandoned. *Touring Cars*.—1, Dr. V. Stern, in 16min. 57sec.; 2, Dr. Suchanek, in 21min. 1½sec.; 3, Lucolf, in 24min. 24½sec.

Heavy Cars in the French Army.

THE heavy vehicles taking part in the army manœuvres in the Vendôme district are doing most excellent work, and the military commission specially deputed to watch their performances are considerably impressed with the possibilities of the self-propelled vehicle for this class of service. The Panhard and de Dietrich tractors have been busily engaged in transporting flour, oats, etc., to the various villages in the neighbourhood, each load weighing upwards of 2,000 kilos. The Scotte train, always kept under steam and ready to get under weigh at a moment's notice, has been engaged upon similar labours, but, of course, with a much heavier load than that carried by the light

oil representatives. As an instance of the nature of the work accomplished by the steamer, I may quote its performance of the 12th inst. On that day the Scotte train, having in tow six wagons loaded with 15,000 kilos of bread, etc., left Vendôme at six o'clock in the morning, and covered 85 kilomètres in thirteen hours, a work which, done by horses, would have required three relays, each of thirty-six animals, and a considerably larger convoy. And the route followed was by no manner of means an easy one, for the commission studying the question are evidently determined to ascertain exactly what the automobile is capable of, and accordingly put it to the severest of tests. Night work has also been accomplished, and little difficulty has been found in operating with this size of Scotte train. This is a step in the direction of solving the trouble which has always been experienced in revictualling, and the military experts are of opinion that by the employment of ten such tractors an army of 72,000 men would be assured of the necessary supplies. Another point in favour of the automobile is that by reason of its shortness as compared with a waggon and team of horses, it necessitates the despatch of a much smaller escort, and furthermore it lends itself with greater facility to defence. It is extremely probable that considerable developments in this direction will be seen in the French army at no far distant date, so satisfactory have proved the recent experiments.

An Automobile Search-Light.

ANOTHER interesting feature in connection with the French manœuvres has been the use made of an electric search-light attached to a small motor-car. During a night attack ordered on Saturday this search-light was extensively employed. The only fault found with the apparatus was that in consequence of its not being placed sufficiently high it disclosed the position both of friends and enemies. The search-light is the invention of M. Marcel Renault.

The Waiter-Automobile.

SHORT as has been its existence the self-propelled vehicle has already been put to a great variety of uses, and not infrequently these have been of a somewhat startling nature. And now an entirely new occupation has been found for it, for among its many previous employments that of waiter has, I believe, never entered into the *role* of the motor-car, and M. Legrand can safely lay claim to be the first to initiate the automobile into the mysteries of this new service. Of course, you will at once say that all this is a joke, but I hasten to assure you that the waiter-automobile is an actuality; and it has arisen in this way. In connection with this year's Paris Exhibition there is, as all the world knows, a great gathering of mayors, and if there is one person on the face of the earth who fully realises the importance of eating and drinking it is a mayor. Obviously, then, an opportunity must be accorded their worship to demonstrate their abilities as trenchermen, so all are meeting to-day at half past eleven in the gardens of the Tuileries, there to partake of a banquet. As the guests muster in all 22,178, of whom 20,777 are mayors, it will at once be seen that the scene of operations occupies considerable space. Placed end to end the tables would cover 7 kilomètres, while the kitchen and the offices similarly arranged would add another 5 kilomètres, bringing the grand total up to 12 kilomètres. Now to aid the army of waiters Monsieur Legrand has engaged the services of two cars, two voiturettes, and four cycles, by means of which the rapidity of the service will be greatly increased and the possibility of any guest being badly waited on reduced to a minimum. It is hardly likely that the automobile will be frequently employed in this capacity, but then banquets for 22,000 guests are not held daily. The motor-car is really a wonderful creature!

M. G. DE MEAULNE has returned from Tunis and Algiers, where he has been organising a "Caravane Algérienne" for October and early next year. M. de Meaulne reports that he has overcome all difficulties in connection with the supply of petrol and other motor accessories.

ELECTRIC TROLLEY OMNIBUS.

WE referred briefly in our last issue to the electric trolley omnibus of M. Lombard-Gerin, described in the course of a paper read by Mr. J. W. G. Aldridge before Section G of the British Association at Bradford. The system is an ingenious arrangement for working omnibuses and other wheeled vehicles in the streets and on high roads by means of an electric trolley upon very much the same principle as the overhead-conductor electric tramway, the vital difference

owing to the heavy expenditure on the track and road bed. The expense of laying down an electric tramway system is, from a commercial point of view, inadmissible in many towns and districts owing to the certainty that the traffic would not repay even a reasonable percentage upon the outlay. Traffic facilities for the increasing population of the outskirts of large towns may be provided either by : (1) The extension of existing tramways. (2) The existing omnibus routes maintained, or (3) motor-cars adopted to replace these omnibuses. The great difficulty in the extension of tramways is the cost of the permanent way,

Clichés de]

FIGS. 1 AND 2.—GENERAL VIEW OF THE LOMBARD-GERIN OMNIBUS AT VINCENNES.

[Le Chauffeur.

being that there is no rail on the road, the return current being effected through a second trolley wire overhead. Mr. Aldridge opened his paper by referring to the one he read at a meeting at Toronto, in which he predicted the general adoption of the overhead trolley system for tramways, and stated how the new system he described would overcome the objections to the tramway, which are twofold, viz. : (1) The unsightly appearance of the

and of track maintenance. Mr. Aldridge in his paper expressed the opinion that the system hereinafter described offers a complete solution of the difficulty. The principal features are as follow :—(1) No permanent way is required ; (2) overhead equipment is reduced to a minimum ; (3) the electric motor-cars have no accumulators to carry ; (4) the system is worked from the same generating station and feeders as the tramway system ; (5) the first cost is, therefore, enormously reduced ; (6) the motor-cars or omnibuses may run through any street which allow vehicular traffic.

The system described is an arrangement by which a service of electric motor-vehicles derives the power from a pair of trolley wires supported on short brackets along one side of the road ; on these wires runs a two-wheel trolley supporting a small electric motor for its own propulsion (Fig. 3), the whole being connected to the omnibus by a flexible cable attached to a pole on the roof, devices being provided for keeping the cable sufficiently taut, and to obviate any risk of derailing the trolley. Continuous current at 500 volts is supplied to the omnibus motor via the trolley wheels and flexible cable, which also, contains three small conductors which serve to convey back to the trolley-motor the three-phase current which drives it. This is derived from the omnibus motor, which is provided with three collecting rings on the armature at the end remote from the commutator, and connected to suitable points in the winding. By this arrangement synchronism is maintained between the speeds of the vehicle and trolley motor, but, in addition, there is provided on the trolley motor an electro-magnetic brake which can be energised at will through a sixth wire in the flexible cable. A trial experimental line on the Lombard-Gerin system is in operation at the Vincennes Annex of the Paris Exhibition (Figs. 1 and 2). The omnibus illustrated is a specially-built vehicle, weighing about three tons empty and five tons loaded, and is furnished with solid rubber tires ; at ordinary speeds the power required to propel it is from 130 to 160 watt-hours per ton-mile on level roads.

overhead wires and supports as generally constructed. To obviate this objection, which is chiefly an æsthetic one, conduit or surface contact systems are being adopted in some towns, but it is certain that the outlay, both in first cost and maintenance, on these systems will in most cases be prohibitive. (2) The cost of electric traction in small towns and thinly populated districts,

In the discussion which followed Mr. Aldridge's paper Major-General Webber and others took part. The author, in reply, stated, while in busy streets it might be desirable to erect wires on both sides of the street, some experiments are being made with a trolley which would pass another running in the opposite direction on the same wires.

FIG. 3

HERE AND THERE.

MONMOUTHSHIRE people are looking forward with much pleasure to the visit of the Automobile Club early next month. Naturally they are interested in the doings of the Hon. C. S. Rolls, and this opportunity of seeing an organised gathering of automobilists will be taken advantage of by most of the county people. In Monmouth the two leading hotels, the Beaufort and the King's Head, will do what they can for the motorists who will be the guests of Lord and Lady Llangattock, on the 8th prox. Lord Llangattock is very popular in the district where he spends a great deal of his time, and his picturesque house, the Hendre, contains many fine curios, reminiscent of distant travels in which Lady Llangattock and his lordship have participated.

AMONG the newspapers published in London is one called *Fun*—a title the reason of which I have been unable to discover. The other week it had some doggerel about "The Motor Car," from which I abstract a sample quatrain:—

When first I saw a motor-car it made me feel quite gay,
I longed to mount and go with it upon a holiday.
I cared not for a horse or "bike," they both of them need toil—
How easy to sit on a motor-car and feed the thing with oil.

Should any motorist meet the "poet" on the road he need not turn his car to avoid contact.

My reference last week to the feasibility of utilising motor-cars in connection with railway services has brought some correspondence, including a letter enclosing a cutting from an Irish paper referring to the probability of a motor-car service being established between Borrisokane and Cloughjordan in Tipperary. It appears that the latter place is served by the Great Southern and Western Railway line, but the former, which is six miles distant, has no such facilities. Hence the suggestion for a motor-car service. There are scores of places in England as well as in Ireland where the population is not large enough to warrant even a light railway, but which would form profitable termini for motor-car services.

SEVERAL commercial travellers are using motor-tricycles in connection with their business journeys, and now Mr. James George, of Keith, N.B., has obtained a motor-phaeton to facilitate his work. The other morning he arrived in Aberdeen to make several calls in the granite city, and in the afternoon set out for Peterhead, visiting customers on the way. Staying at Peterhead for the night, he started on the following morning on a journey to Longside, Old Deer, Maud, and other places throughout Buchan.

OTHER "commercial" should follow his example as far as possible. Why could not three or four travellers, representing houses in different trades and going the same journey, join together for the hire of a motor-vehicle to carry themselves and their luggage from town to town? Such an experiment would be of considerable interest, and when a motor firm has a few slack moments it might consider the details of such a notion.

THE motor-vehicle has been a familiar object at hunting meets this season, being employed mainly in connection with the commissariat. In America things have gone a step further, and Colonel J. J. Astor, mounted on his car, was in at the death at a recent fox hunt at Newport. It will be a long day before motor-vehicles are similarly employed here, but I shall be glad to hear of their use in connection with the transport arrangements of sportsmen and hunting parties generally.

HEAVY motor-vehicles are becoming numerous in London, evidence that, despite the relatively heavy initial outlay, the economy of motor as compared with horse traction is slowly but surely being realised. As is well known, several of the vestries have adopted them for dust collection, street watering, and other purposes, while many large industrial concerns, notably Messrs. Spiers and

Pond, Messrs. Schweppe's, Messrs. W. H. Smith and Sons, and Messrs. Fuller and Co., have been using them for some time. The latest addition to the list is the Val de Travers Asphalt Company, Limited, who have just put in service a Thornycroft steam wagon. The other day I happened to be in Fore Street, E.C., which thoroughfare is just now, like a dozen other City streets, undergoing repairs, and saw the new van at work. Naturally it attracted much attention from passers-by, for a score or so of labourers were busy loading it up with old road material, and when the vehicle itself was full a trailer was attached. After this had also been loaded up with material the steam wagon hauled its heavy load away without any difficulty, much to the surprise of many of the onlookers and the amused curiosity of those who had loaded it.

One minor matter about the lorry which attracted my notice was the unprotected water-gauge attached to the tank at the rear. From what I saw of the operation of loading, I would suggest that some protection had better be provided for this glass, otherwise frequent renewals may be necessary. Or perhaps the labourers might be given special training in loading, for, judging from the performance in Fore Street, the gauge glass will not be missed every time.

AMONGST the successful motor-car services which have been established is that which Mr. W. H. Hollier has provided for the visitors to Aberystwith. This has been running two seasons,

with increasing favour, and next year some longer trips with higher powered cars are contemplated. Herewith I give a snapshot of a merry party on one of Mr. Hollier's cars, supplied by the Motor Manufacturing Co.

MOTOR-VEHICLES of every sort and description may always be seen on the road to Guildford, the steep High Street of which is an uncomfortable termination to one of the prettiest jaunts out of town. Nearly every village on the way is associated with cycling expeditions and known to cyclists throughout the country. Just on the way to Esher are two interesting things which have often aroused the interest of motorists who have been eager to get along, and who have not cared to stop and inquire their history. The first is the much ornamented enclosure of Sandown Park with its gilt railings and great gas lamps. These once served to decorate the luxurious mansion built at Kensington for the late Baron Albert Grant. A little further along on the right is an alcove built a century ago by the Rt. Hon. Henry Pelham, as the initials "H. P." serve to indicate.

THE other day returning from Guildford I met one of the finest motor "turn outs" I have yet seen on English roads. We had reached the great central square at Epsom when a 12 h.p. Panhard wagonette passed by. It had a natural wood body, which gave it a stylish appearance, and with eight people aboard it had evidently been going at a good pace. The driver was be-goggled and the car be-dusted—two facts which indicate "twelve miles an hour," or thereabouts.

THE NICOLAS PETROLEUM-SPIRIT MOTOR.

AMONG the many petroleum-spirit motors recently introduced in France, one of the most novel is that made by M. Paul Nicolas, and illustrated in Figs. 1 to 3 herewith. The balancing of multiple-cylinder motors is a question which has engaged the attention of engineers for many years past, and numerous designs have been tried, with a view to attaining a

FIG. 1.—SIDE ELEVATION.

simple mechanism and a well-balanced motor. It will be seen that the Nicolas engine, which presents some distinct features of novelty, comprises four cylinders placed at angles of 90 deg. around the crank chamber, the single crank shaft passing through the centre of the chamber in the usual way. The cylinders are provided with radial discs for cooling purposes. The connecting rods *D* are fastened to the crank pin *E* in a special manner. The heads of the rods are of segment form; the

FIG. 2.—SECTIONAL ELEVATION.

exterior surface of the segments is circular, and the two sides conical. On the latter bear two rings, the interior of which is of a corresponding conical form, and which screw on to two rings placed on each side of the crank. In this way, the heads of the four connecting rods are solidly connected to the crank pin, at the same time permitting of any wear to be taken up. The head or combustion chamber of each cylinder is provided

with an admission box composed of two compartments *d* and *e*, separated by a metallic diaphragm *f* (Fig. 2). A single valve *g* is connected with this box, and, working automatically, permits the entrance of the explosive charge. The two compartments of the box communicate with one another by means of small holes *h*. On admission the valve *g* opens, and the diaphragm permits fresh air to enter by the pipe *i* into the gas chamber *e*, where it is intimately mixed with the gas which enters by the pipe *j*. On the other hand, when the suction of the piston ceases, the gas which fills the lower compartment *e*, causes the diaphragm *f* to bear on and close the air entrance holes *h*, and also prevents the gas escaping. The action of the diaphragm valve is entirely automatic, and effectually prevents the escape of gas, while ensuring perfect mixture of the charge in the combustion chamber. The electric ignition was originally effected by the rods *Z*, whose ends made contact with a cam on an insulated sleeve attached to the rotating sleeve *N*. This arrangement has now been discarded, and an ordinary commutator ignition adopted. An examination of Fig. 3, which is a cross vertical section through two cylinders and the crank chamber, will show the arrangement of the exhaust valve gearing. Each cylinder is provided with an exhaust valve

FIG. 3.—CROSS-SECTION.

l, so arranged that the latter can be quickly removed in case any repair to the valve becomes necessary. The admission and exhaust valves are kept on their seats by means of spiral springs, the tension of which may be regulated as desired. The exhaust valves are controlled by means of a cam *N*, with four projections *n*, mounted loosely on the crank shaft *T*. This cam *N* only makes one revolution to two of the crank shaft, this being obtained by means of the reducing gear wheels *QQ*¹ (Fig. 3), the smaller of which drives the toothed portion of the periphery of the cam *N*. Each of the projections *n* having to control only one of the exhaust valves, the cam *N* has, of course, to be sufficiently wide to permit of their being arranged in different planes. The operation of the motor is as follows:—With the cylinders in the position shown in Fig. 2, and with the engine running in the direction shown by the arrow, cylinder No. 1 is commencing to draw in the mixture of air and spirit, cylinder No. 2 is at the centre of the compression stroke, cylinder No. 3 is commencing to exhaust, while cylinder No. 4 is at the centre of its impulse stroke. It will thus be seen that explosion and compression take place simultaneously in two opposite cylinders, thus greatly relieving the structure from vibration, one movement serving to a great extent to counter-balance the other. M. Nicolas has already completed a number of these motors for vehicle propulsion purposes. The engine illustrated is of 8 h.p., having cylinders 72 m.m. diameter with a stroke of 105 m.m.

AUTOMOBILES IN FRANCE.

(From Our Paris Correspondent.)

IT is extremely difficult, one might almost say impossible, to reconcile the figures quoted by *Le Vélo* in a recently issued statistical table dealing with the number of automobiles actually in circulation in France at the end of last year, with what we know of the French automobile industry. According to these statistics the number of motor-vehicles throughout the entire country only totals up to 1,672, of which Paris claims but 288. It really seems incredible, and I doubt whether anyone in France, no matter how closely connected he might be with the automobile movement, would have estimated the number of vehicles in use at anything like so moderate a figure. For my own part I would have considered 2,500 a very inside estimate, and 3,000 would not have surprised me. But 1,672 passes all belief. Why here at Paris we have seen on more than one occasion 300 cars assembled together, and even supposing that every owner in the capital was then present it is obviously improbable that every one of his vehicles—and many men own several cars—was on the spot. When one has witnessed at some race or fête a gathering of vehicles such as this, one cannot but be astounded at the figures of the Minister of Finance. Then, too, a moment's consideration of the output of the leading constructors adds to the difficulty of reconciling these statistics. During the last five years certain manufacturers—not many certainly, but two or three without doubt—have had a continuously steady output, and although all the cars built are not now in use, still one would have readily expressed the opinion that the number of vehicles built by these firms alone, and now in use, would have considerably exceeded the total quoted.

Exportation certainly cannot account for the difference, for England has been the best customer for France's automobiles, and one knows how many are to be seen in England. Therefore the difference cannot be put down to that cause; and the accuracy of the official figures is, needless to say, beyond reproach, and the certainty that few, if any, self-propelled vehicles escape the tax is also beyond doubt. All this being so the question simply resolves itself into the fact that one and all of us are so accustomed to hear and to make exaggerated reports as to the output of constructors that we quickly arrive at belief in the figures ourselves, and are absolutely astounded when we ascertain that they are but delusions. Everyone in his turn adds a little to the figures given to him, and ultimately all become convinced of the accuracy of the statements, and it requires an official report to open our eyes. It is so easy to say, "Oh! yes, so-and-so turn out four cars a week," when but three are actually constructed in that time, a small difference in itself, but a consideration in the course of twelve months. Of course, in dealing with these figures it must be borne in mind that no motor-cycles are included, but here is the exact table as taken from *Le Vélo*:

	Cars of more than two seats.	Two seated cars.
Communities of 5,000 inhabitants	313	256
Do. 5,001—10,000 inhabitants	104	92

	Cars of more than two seats.	Two seated cars.
Communities of 10,001—20,000	87	96
Do. 20,001—40,000	75	60
More than 40,000 excepting Paris	163	138
Paris	204	84
	946	726

I may mention that this classification is followed by reason of the fact that in France the tax payable on automobiles varies with the number of seats which they possess and the population of the town in which they are registered as expressed in the above table. The motor-cycles are included in the cycle returns, which for the year 1899 showed a total of 838,856 registered machines, figures almost double those of the preceding year. Since last December the number of motor-vehicles in use has very greatly increased, and when the figures for the year 1900 shall have been published one will find a very considerable advance upon the meagre return for 1899. But in the meantime the statistics published are distinctly disappointing.

THE ENGLISH MOTOR CLUB'S MEET AT LUTON—READY TO START FOR BEDFORD.
[A. J. Anderson & Co., Luton.]

JOSEPH WHITFIELD, of Darlington, was summoned, on Monday, for being drunk while in charge of a motor-car at Croft on the 1st inst. Defendant was fined £1 and costs.

THE Rural District Council of Romney Marsh have had before them the question of the excessive speed at which motor-cars travel over the highways in the district. After discussion it was decided to bring the matter to the notice of the Chief Constable of the county.

A GLOUCESTER firm has just had its excursion to Bournemouth. The principal attraction of the day was the motor-car

trip to Boscombe, which was much appreciated, and the hope was expressed that Gloucester would quickly adopt such a form of locomotion.

OUR French contemporary, *L'Avenir de L'Automobile*, is getting up a subscription with the object of presenting Le Comte de Dion and M. Bouton with a testimonial and *objet d'art*, in recognition of the services which they have rendered to the creation and development of the automobile industry.

LAST week George Barron, the driver of a motor-car, and Evan Thomas, the driver of a brake, had a long run together in the straight portion of Cardiff Road and Aberaman. P.C. Senior, however, was on the watch and timed them, with the result that they had both to appear at the Aberdare police-court on Tuesday charged with furious driving. They were each fined 20s. and costs.

AT a meeting of the Upper Ward Committee of the Lanarkshire County Council on Monday information was read from the police in regard to the furious driving of a motor-car on the public road near Lesmahagow, at an estimated rate of thirty miles an hour, by Mr. John Stirling, of Stirling Motor Carriages Limited; James Andrew, the foreman engineer of the same company; and Wm. Dodds, engineer, on September 3rd. The Chairman said there were seven witnesses who estimated the speed at thirty miles an hour. It was agreed, with one dissentient, to prosecute.

THE LOUTZKY MOTOR-VOITURETTE.

FIG. 1 of the accompanying illustrations shows a one or two-seated light car which has lately been put on the market by the Gesellschaft für Automobil-Wagenbau (system Loutzky). It is fitted with a single-cylinder air-cooled motor, of which two sectional views are given in Figs. 2 and 3. The

FIG. 2.—THE LOUTZKY VOITURETTE.

engine, which is capable of developing 2 h.p., is provided with electrical ignition; it is geared direct by spur wheels to the rear axle, a two-speed gear controlled by the handle projecting up through the floor of the car being provided. The front wheels are, it will be noted, carried in forks

FIGS. 2 AND 3.—SECTIONAL ELEVATIONS OF MOTOR.

of the type employed in bicycles, the steering being controlled by a long bar connected to these forks. The speeds can be varied from 4 up to a maximum of 25 kilomètres per hour on the level, while it is claimed that the car, which weighs complete about 4 cwt., can mount 10 per cent. gradients.

THE Locomobile Company of America, New York, is constructing a number of mail wagons for the U.S. Government.

MESSRS. CHAVANET, GROS, PICHARD, AND CO., of St. Etienne, have sent us a copy of their new list of Automoto motors and motor-cycle and car fittings. The firm have recently introduced a useful series of front and rear axles for voiturettes and heavy cars.

ARE STEAM CARRIAGES DANGEROUS?

THE criticisms which have been made in England and on the Continent regarding the design and safety of the small fire-tube boilers used in steam carriages on the Stanley lines do not impress us as being very weighty, remarks the *Horseless Age*. The opinion was expressed by M. Amedée Bollée at the recent Automobile Congress in Paris that it was imprudent to put a boiler of this kind on a carriage, on account of the risk the user ran if the feed did not act properly—a danger alleged to be enhanced by the difficulty of keeping an eye on the water gauges. As it is on account of the supposed danger from low water that boilers of this class are not permitted on the public roads in France, the objection calls for serious consideration even if it does not command assent.

As a matter of fact, it is only a question of money, material, and design to build any sort of a boiler to withstand any given conditions. If for whatever reason it is desirable to have a boiler that will run dry without exploding, and if the need for it is such as to justify the cost of making it, there is no reason in physics or engineering why it cannot be done. What makes the cylindrical boilers of the ordinary designs—Scotch, Lancashire, etc.—so dangerous in the event of low water is that they have crown sheets or flues, which, if suffered to become red-hot, will collapse, tearing open a seam and causing rupture of the boiler. The water is not expected to get low in these boilers, and no provision (other than safety plugs) is made for such an occurrence. The Stanley and similar boilers, on the other hand, have neither flues nor crown sheets, properly so called. They are simple cylinders, with small tubes extending from end to end and expanded into the heads. There is, therefore, nothing to collapse, even if the whole boiler were made red-hot. As to bursting, the expense of making the factor of safety double or treble what it is in larger boilers is so small that it may be, and is, ignored; and this provides not so much for undue pressures, which are prevented by the safety-valve, but for deterioration in service.

This, of course, is not to say that the Stanley type of boiler can be run dry with impunity. On the contrary, it is, after such an experience, if not actually ruined, at least a very promising candidate for the hospital. The overheating and the unequal expansion thus induced cause the tubes, some or many of them, to leak at the ends. This relieves the pressure and prevents casualties, but it puts the boiler out of service till the tubes are made tight once more. In this connection the experiment made a few months ago by the makers of one of these boilers is worth remembering. They put a boiler, with water in it, over a fire in an excavation in the ground. All valves were closed, and a pipe was led off to a distance, where a steam gauge was connected. The pressure shown by the gauge rose to 1,200 lb., at which it stopped. At this pressure the joints between the tubes and the sheets began to open, and the steam gradually escaped till the water was exhausted.

A perhaps more important objection, which might have been raised by European critics, is the possibility of deterioration by grooving, pitting, electrolytic action between the steel and copper where two metals are employed, and kindred ailments, common enough and discoverable by inspection in large boilers, but which can only be guessed at in the small ones. Very likely that was what Sir David Salomons had in mind when he objected to these boilers on the ground that their interiors are inaccessible. Grooving might take place at the bend where the tube sheets are flanged, if the bend were made too sharp, especially if copper tubes were used with a steel shell; or it might conceivably occur at the longitudinal seam if this were lap instead of welt. The obvious preventives, however, are a liberal radius for the bends, and the use of welts; and until some evidence to the contrary appears we shall be quite willing to regard the large factor of safety as sufficient provision against failure from pitting and kindred deterioration.

In large boilers an excessive incrustation, by preventing the water from absorbing the heat rapidly enough, is liable to lead to failure of the tubes and sheets; and this matter of incrusta-

tion is really the most troublesome feature of the small boilers. Whether or not it is dangerous, however, can best be settled by experience. We should rather expect to find that the carriage boiler whose tubes and bottom sheet were so thickly incrustated as to over-heat would not be very efficient in taking that carriage up-hill. In other words, the carriages are not so over-boilered that any serious diminution in efficiency could be neglected; and this, of course, is as it should be.

Assuming, however, the vehicle to be worked so lightly that by continued additions of scale the lower part of the boiler is heated, step by step, beyond the safe limit, the question is, when the failure comes, will it be local and without an explosion, or will it take the form of an extensive rupture, "bursting" the boiler and destroying whatever may be in its way?

To our perception of the matter, one of three things may happen. Obviously the weakening of a few isolated tube joints will not afford relief, since the scale will prevent the water from escaping. Such weakening, however, would throw added strain on the adjacent joints, and these would quickly follow suit, with the result that the lower tube sheet would presently bulge at one or more points, letting the water escape, and perhaps extinguishing the burner by the steam thus formed. This would happen if the incrustation and the consequent weakening were mainly local, or it would happen if for any reason one part of the lower tube sheet were more heated than the rest. If the overheating were general, however, the failure of each successive tube joint would leave the next ones less able to carry the pressure, and the result might be a general and practically immediate giving-way of all the joints in the bottom sheet. This would practically amount to an explosion, even if the bottom sheet were still held to the shell by the circular seam; while if the latter, softened by the heat, gave way also, the explosion would assume its most violent form.

No such cases of failure as those we have just outlined have, adds our contemporary, come under our notice. It may be doubted if they would even be possible while the boiler continued to do duty at all; and certainly the victim of such an accident—if by good luck it carried off the individual responsible for its occurrence—would have only his own stupidity to blame for his fate. Nevertheless, the point seems worth discussing, if only because it is the only obvious way in which these boilers could be made to explode. Actual data regarding the behaviour of carriage boilers are regrettably meagre, and especially so as regards their life and the frequency of repairs. As they are commercially so very recent, this is only to be expected; but it is not too early for some information to be available. "An ounce of practice is worth a ton of theory," and we shall be glad to publish any such particulars as our readers may be able to give us, for the benefit of all concerned.

THE Meyra Electric Company have removed from Newman Street, W. to more extensive premises at 78, York Road, King's Cross, N.

THE New York Post Office department reports a saving of fifteen minutes per trip as a result of its tests with motor-vehicles for the collection of mail in the downtown districts.

MR. W. L. BODMAN, whose newly-formed connection with the Milwaukee Automobile Company, of Milwaukee, U.S.A., was recently reported in our columns, expects to have a steam omnibus, embodying his designs, completed by next November. He returns to Europe this month to settle up his affairs prior to making his permanent home in the United States.

It is the intention of the Automobile Club of America, at their exhibition in the Madison Square Garden in New York next November, to make a display of a number of racing automobiles, as well as a number of foreign cars. They are also arranging to add to the exhibit any early experimental motor-carriages which they can obtain, as they believe these will be of considerable historical interest.

THE DE DION TRICYCLE INDUCTION COIL AND ITS CONNECTIONS.

MESSRS. DE DION, BOUTON AND CO. have recently adopted a new induction coil in connection with the electrical ignition on their motor tricycles. The device, which is made by Messrs. Bassée and Michel, of Paris, is known as the "three terminal" type, one terminal being at the right and the other two enclosed in the left hand end, holes being provided for the ignition wires to pass through. The

accompanying illustration, which has been furnished us by the United Motor Industries, Limited, who handle the device in this country, so clearly shows the method of connecting up the coil with the battery, contact breaker and sparking plug, that no lengthy description is necessary.

THE Rose Polytechnic Institute, of Terre Haute, Ind., U.S.A., will in future devote special attention to the automobile in its course of study.

THE flowing robes and new motor car of Wu Ting Tang, the Chinese representative in Washington, are said to be familiar sights, generally seen together in the streets of America's capital.

AUTOMOBILISTS who reside in or who may be passing through the Oxford district will find their wants in the way of petroleum spirit and motor accessories supplied by Mr. T. G. Barton, of 11, George-street, Oxford. Mr. Barton, who is agent for Oxford, Abingdon, and district for the "Mayfair" voiturette, is also well equipped to carry out repairs to motor-cars and cycles.

AN interesting innovation in connection with exhibitions will be introduced at the permanent automobile exhibition which is about to be opened in Berlin. It would, of course, be rather expensive for the exhibiting firms to have a representative constantly in attendance, so the director of the exhibition has conceived the idea of using the phonograph to expound the merits of the various machines, etc. The management has procured several phonographs, and a cylinder for each exhibitor. A description, containing the most important points, accompanies each exhibited article, and these descriptions are recorded on the cylinders. If a visitor desires any information concerning a certain article, the attendant of that section places the corresponding cylinder in the phonograph, and puts the latter at the service of the visitor. The instrument is entirely at the visitor's command, and may be stopped and restarted as often as convenient.

FURIOUS DRIVING CASES.

At the Steyning Petty Sessions, on Monday, Herbert Lonsdale, of Brighton, was summoned for riding a motor-car at a pace dangerous to the public at Shoreham. P.S. Beacher and two constables swore to seeing the defendant's motor-car going at from eighteen to twenty miles, in Shoreham High Street. Defendant was fined 2s. 6d. and 13s. costs.

At Barry Police Court, on Monday, William Gunning was charged with furiously driving a motor-car on the highway. Acting-sergeant (Hill said that on the 1st inst., in company with Inspector Morris, he saw defendant driving a motor-car along Holton Road, Barry Dock, at the rate of thirteen or fourteen miles an hour. Defendant told him that he was only going at the rate of twelve miles an hour. Inspector Morris corroborated. Gunning said he had been driving a motor-car for five years in London, where, however, he had also been summoned. No one was in danger on the present occasion. The Bench fined defendant 40s. and costs, the maximum penalty.

At the Beverley Borough Police Court, on Monday, Henry Lovaggi, of New Park-grove, proprietor of the East Riding Cycle Company, Hull, was summoned for driving a light locomotive at a pace to be dangerous to persons using the highway, on the 6th inst. Supt. Knight stated that the summons was taken out consequent upon what happened near the Beverley Gasworks on the date in question. The defendant was driving a light motor-car into Beverley from Hull. Near the gasworks there was a bend in the road, which he negotiated so quickly that a horse and cart being driven by Mr. Loft towards Woodmansey was upset, and the driver thrown out. It was alleged that defendant came round the corner at the rate of ten miles an hour, and although the Act gave drivers of such cars power to go at the rate of fourteen miles an hour, it was expected that they would use due care for the safety of persons using the road. Joseph Lyon, Emily Elizabeth Robinson, and Robert Loft also gave evidence. Mr. Hare, who appeared for defendant, contended that there was no evidence that defendant was driving at an unreasonable speed when the accident took place. Defendant said when he passed Lyon he was going at ten miles an hour; he travelled over the bridge at the rate of six miles, and when the accident happened he was only going at the rate of three or four miles. Cross-examined, defendant stated that he had offered to consider the question of compensating Loft for the damage to his apples. But he was asked a sum he considered to be an imposition. He had been warned about the pace he travelled, but he had never been interfered with by the police before. The Bench considered the case proved, and fined defendant £1 and costs.

MR. FRANK MORRISS, of London Road, King's Lynn, has been summoned for furiously driving a motor-car.—P.C. Boliston said that while he was in South Everard Street about 10.45 p.m. on the 6th inst., he saw a motor-car going along London Road at a terrific rate from the direction of the South Gates. The speed could not be less than twenty miles an hour. He could not see who the occupants were, but after making inquiry he went to Mr. Morris's house on London Road, but did not see the motor-car. He saw defendant through a window, and asked him if he had just passed in a motor-car, to which he replied: "Yes; I will admit I was driving at an excessive rate." [Defendant: That's untrue.] That statement defendant made in the presence of P.C. Thrower. William Cliff, of Pleasant Row, in the employ of Mr. E. Fysh, cab proprietor, said he was with a cab outside Mr. P. T. Chatterton's house on London Road, and saw the motor-car pass at about eighteen miles an hour. Mr. Morris and a lady were the occupants.—Mr. Sadler, in defence, said the charge was that of furiously driving the car to the danger of the public, and defendant denied that he did so. The road was a wide one, it was a moonlight night, and there were no people about. Mr. Sadler said he hoped the Bench would not convict, and remarked that defendant was the pioneer of the motor-car industry in this district.—Defendant said he had been to Yarmouth that day, and on his return stopped at Swaffham. He left there about ten minutes to ten o'clock, and arrived in Lynn about eleven o'clock, the distance being about fifteen miles. When he got into Lynn he slowed down. He would not drive along London Road at such a rate as the constable declared he did, because the car was a good one, valued at £600.—In answer to the Chief Constable, defendant said it would be about a quarter to eleven when he got home.—Mr. Ayre said the Bench had come to the conclusion that he was driving at a dangerous pace. Mr. Morris would be fined £1 ls. and costs.

At the Isle of Wight County Petty Sessions at Newport, on Saturday, Captain H. R. Langrishe, the Royal Yacht Squadron, was summoned for furiously driving a motor-car. For the prosecution a police constable said he saw the defendant driving a motor-car in the High Street, where there was a lot of people about. He was going at the rate of nine to ten miles an hour. In cross-examination by Mr. Firth, he admitted he did not speak to the defendant. A porter also gave evidence. At the conclusion of the evidence for the prosecution, Mr. Firth raised an objection to the summons. He said it was well-known law that no man could be tried for two particular offences arising out of the same occasion, and, notwithstanding this, his client was summoned for driving his carriage at a speed that was greater than was reasonable and proper in the High Street, having regard to the traffic there, so to endanger the life or limb of any persons thereon. Mr. Firth pointed out that by Article 4 of the Local Government Rules, the regulations were sub-divided into two different offences. It was an offence to drive at any greater speed, having regard to the traffic on the highway; it was also an offence to drive a

motor-car so as to endanger the life or limb of any passenger on the highway, and he pointed out that it was incompetent for the prosecution to couple the two offences in the summons, and that on this ground the charge should be dismissed. The Bench found that a mistake had arisen, and that the summons was bad; whereupon Mr. Firth contended that the case should be dismissed, but the Chairman stated he should amend the summons. Captain Langrishe said he got into the car, accompanied by Lady Affleck, at the London Club, that his valet there started the engine, and that he drove down the High Street to the Pontoon, that his servant walked after him and arrived within twenty seconds of his arrival at the end of his journey, so that instead of driving ten miles an hour he only went at a walking pace. Captain Langrishe's valet gave confirmatory evidence. In his speech for the defence, Mr. Firth characterised the case as "trumped up by the police." Ultimately the magistrates came to the conclusion that they were prepared to dismiss the summons and give Captain Langrishe the benefit of the doubt.

THE CHELTENHAM COACH ACCIDENT.

THE Cheltenham coroner has concluded his inquiry into the circumstances of the death of Mr. Thomas Bugbird, which occurred from the rupture of a blood-vessel, occasioned by falling from a coach on August 29.—The Coroner explained that all the injured persons except deceased had recovered.—Mr. Walter Coyney, the driver of the coach and an experienced amateur whip, stated that the horses were walking when they passed Mr. Bingham's motor-car on Hunting Butts Hill. The motorist stopped the car when requested by witness, but the great vibration of the motor frightened the horses. The road was narrow, and the near side-wheels went three feet up a bank, jerking witness and two passengers off. Then the horses bolted and collided with a tree, and the rest of the passengers, including deceased, fell off. If witness had been strapped to his seat the horses would not have got out of control, as they had safely passed motors before.—Captain Hunt, the owner of the coach, said he would have driven past the motor-car without stopping it, so as to get away from the exceptional noise as soon as possible. He did not blame either driver or motorist.—The jury returned a verdict of "Accidental death."

MOTOR-CARS AND FRIGHTENED HORSES.

A CASE of some importance to those interested in motor-cars came before Judge Stonor, on Tuesday, at Brompton County Court. The plaintiffs, the Coupé Company, Ltd., 75, Britannia Road, Fulham, London, W., sought to recover damages from the Motor Traction Company, Ltd., 133, Finsbury Pavement, E.C., with respect to the smashing of a coupé, through the negligence, it was said, of one of the drivers in the employ of the defendant company. J. Williams, a driver employed by the plaintiffs, stated that on March 1st last he was driving a coupé along Buckingham Palace Road, and when near Victoria Street he saw a motor-bus coming towards him. Seeing that his horse was becoming rather restive, he held up his hand and shouted to the driver of the motor to stop. The latter, however, continued to approach, and witness's horse shied, overthrowing the coupé on to its side, causing considerable damage. Cross-examined by Mr. C. Walsh, counsel for the defendants: Both he and the driver of the motor-bus were on their proper side of the road. The motor was not proceeding at an exceptionally great speed; there was no smoke issuing from it, but it made a great noise. The Judge: How far away was the motor when you first saw it? The witness: About thirty or forty feet. Mr. Walsh: The instructions given to our drivers are to stop whenever it may be necessary, but I am not aware that any other drivers have a right to control the travelling of motors. The Judge: Suppose a man had a heavy van load of iron, and his horses became frightened at the noise of a motor, I am not sure that the people belonging to the latter would not be liable for any accident that might occur, if they did not stop when requested to do so. William Addie, the driver of the motor-bus in question, was called, and denied having seen plaintiff's driver hold up his hand or heard the man shout for him to stop. The Judge: I do not see that there was a want of reasonable care on the part of the defendants' driver, and I shall strike out the claim, with costs.

WE understand that the claim of Mr. Rucker against the insurance company in connection with his recent motor-car accident has been settled to his satisfaction. Mr. Rucker sailed for the United States on Wednesday.

In a recent court decision at Binghamton, U.S.A., in the case of a summons for exceeding the ordinance of eight miles an hour, the policeman making the arrest swore the motor-vehicle started from a standstill, and from that point (which was the position of the guardian of the peace) turned a corner, crossed four tramway tracks, there being two switches at that point, heavily paved with cobble rocks of long standing, crossed a crossing over which people were passing, and came again to a standstill at a point distant from the start of about 500 feet, and within the distance the wagon had travelled at the rate of fifteen miles an hour!

THE Motor-Car Journal.

Vol. II.]

LONDON, SATURDAY, SEPTEMBER 29, 1900.

[No. 82.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

AT the General Election motor-cars will probably play an important part—certainly they will be employed by the candidates in South Hants and North Ayr, while the Hon. J. S. Montagu and Mr. H. W. Forster would probably mount their cars and ride to victory should opponents decide to take the field against them. In the Horncastle division of Lincolnshire, where the candidates are Lord Willoughby de Eresby and Alder-

man T. Wallis, the constituency is being scoured by the aid of motor-cars. The Liberals, it is said, started by introducing a couple of motor-cars, and the Conservatives have chartered half-a-dozen with which to whip up their followers. In another Lincolnshire constituency Mr. Herbert Peake is getting from place to place on a motor-car, thus obtaining a distinct advantage over his opponent, who is looking after his interests on a bicycle. We understand that practically everyone in London who has motor-vehicles on hire has been approached with a view to their being used in the elections, and that many provincial firms have let out all their motor-cars to the friends of candidates.

Mr. Broadhurst and Automobilmism.

MR. H. BROADHURST represents the place of his residence on the Norfolk County Council, and in that capacity has had to utter a warning against the reckless driving of motor-vehicles. He also represents the important town of Leicester in Parliament. Now it so happens that at Leicester there is a motor-car service which is of great public convenience. One of his constituents, recognising this latter fact, has written him on the subject, drawing forth a letter which should be welcome reading to all interested in the progress of automobilmism. Mr. Broadhurst says he occasionally rides a motor-car himself, that he has said nothing about numbering vehicles, and that he has never said all motor-car drivers were wild. Evidently he is on the side of the automobilists.

To South Wales.

THE Automobile Club's tour, which it was thought at one time would have interruption from the General Election, will take place as already arranged. Several members of the club have already intimated their intention of participating in the run. Three nights will be spent at Monmouth, and in addition to the invitation to lunch at The Hendre an invitation has been given by a well-known member of the club to visit some important iron works in the locality. Given fair weather a very pleasant excursion should result.

The English Motor Club.

SATURDAY'S run of the English Motor Club was to Wendover, and about a dozen members participated—including Mr. Barnes on his Benz, Mr. W. H. M. Burgess on a quadricycle, Messrs. Gladding, Baily, Moyle, and others on motor tricycles. On Sunday the party lunched at Thame, and then

returned home *via* Reading. On the Saturday we had gone part of the way on the road and found it very dusty—as dusty, in fact, as we have known it this season.

Engine Drivers and Motor-Cars.

THE other day Mr. C. Jarrott took an engine-driver for a ride on Mr. S. F. Edge's famous Napier car. It was a pleasant trip for all concerned. They went from London to Biggleswade, St. Neots, Bedford, and home again *via* Luton—and all in a very short space of time, full details of which need not now be revealed. After the engine-driver had got over the newness of his experience in riding without the worry of looking out for signals, he settled down to enjoy the experience. He grew enthusiastic, and declared that the speed was sixty miles an hour—which was, of course, rather beyond the actual pace. One thing, he is certain that motor-vehicles *can* go. During the trip a timber-laden van passed, and the projecting timber nearly caused an accident such as that which overtook Mr. Rucker's car in Hampshire. Really there ought to be special regulations as to such vehicles.

Accidents in France.

ACCORDING to the *Velo's* return of accidents for July last, the automobile has hardly been so blameless during the month as is its habit, but all the same fewer accidents can be laid to its charge than in the case of the three other principal means of locomotion. The motor-vehicle is held responsible for twenty-eight accidents, in three instances these being fatal ones. In one case the victim was a pedestrian but in the other two the *chauffeur* himself met his death. In the first instance an old lady, half blind and deaf, was knocked down by a car passing through Magny-en-Verin (Seine et Oise) and succumbed the following day to a fractured skull. At Longwy a motor-cyclist fell from his machine and died almost immediately, while upon the same day, at Ville d'Avray, M. Jacques Ellisen was thrown from his car and killed on the spot. This is the motor-car's black list, and the record which most nearly approaches it for moderation is that of the railway. Here we find fifty-four accidents, bringing eleven deaths in their train. The bicycle has caused 117 mishaps, and claims ten fatalities, while the horse's record runs up to no less than 630 accidents and 68 deaths. The grand total, therefore, amounts up to 897, resulting in 92 deaths.

The French Heavy Motor-Vehicle Trials.

WE learn that a party of members and friends of the Liverpool Self-Propelled Traffic Association is being formed to attend the *poids lourds*, or heavy motor vehicle competition, which is to be held in the neighbourhood of Paris from the 8th to the 13th Oct. It is intended to meet at Charing Cross Station, at 8.30 a.m. on Sunday, the 7th prox., and journey to the French capital by the Dover-Calais route, but, as a large number is not expected, no special arrangements for fares or accommodation will be made. Members can, therefore, return from Paris at their own convenience. Mr. E. Shrapnell Smith, the hon. secretary, is, we understand, arranging for seats for members on the competing vehicles.

Motors and Milk.

VERY enterprising have been the leaders of the modern movement in connection with creameries in Ireland, and now some of them are inquiring as to the conveyance of milk from the farms to the butter factories by motive power.

From one place where the matter has been mooted we learn that vehicles to carry from two to three tons would be required. They should be fairly speedy as some of the distances to be traversed are long and in outlying districts. Any particulars as to cost, type of vehicle, etc., which readers may have will be welcomed in our columns. With such inquiries before us, and so many Irish people anxious to have a visit from the Automobile Club, it would appear that there is good ground for automobile development across the Irish Sea.

A Motor-Car Smash.

DESCRIPTIVE reporters had a fine chance on Monday. Dr. Heath, of London, with two friends, was returning to town from Grange by motor-car. After a halt at Kirkby Lonsdale, they proceeded down Brig Brow to the noted Devil's Bridge, when the brake failed to act, and the car rushed off at a terrific rate. Before reaching the bridge it dashed into the iron railings at the entrance to Lunefield, the residence of the Countess of Bective. The car was smashed to atoms, and "blew up with a resounding report." Dr. Heath was found under the debris, and when examined by Dr. Ledger and Dr. Paget Tomlinson was seen to be suffering from injuries mainly on the upper part of the body. The two friends escaped with a shaking. Dr. Heath's injuries are not so serious as was at first thought.

THE GORDON-BENNETT INTERNATIONAL CHALLENGE CUP.

Typical Adjectives.

THE foregoing is a typical illustration of the class of adjective reserved for such exploits:—"a terrific rate," "smashed to atoms," "resounding report." Then the last line is equally typical of the way in which these paragraphs usually end—

"The injuries are not so serious as was at first thought." Why cannot journalists get to the last line of their reports before writing the headline?

A Veritable Death Trap.

THE road between Horsham and Dorking, although somewhat hilly for a portion of the way, is a popular one with both motorists and cyclists. Entering Ockley, the road is a straight one, and looking ahead it is seemingly continuous, but as the road is followed a gate suddenly appears in front. There is no warning notice and the gate is always closed. Upon looking closely a very narrow lane, with projecting hedges on either side, is seen on the right, and round this suddenly the traveller has to turn. A more awkward and dangerous corner we have never seen. Many cyclists have run into the gate and have been injured. A friend of ours, a few years ago, while on a driving tour, ran into the gate one dark night, injuring his horse and smashing the trap. The latest accident occurred last week when a voiturette, driven by a gentleman accompanied by a lady, ran full tilt into the gate, with the result that the motor-car was seriously damaged. Fortunately the passengers escaped with nothing more serious than bruises. The gate was smashed to pieces and the fragments are still lying by the side of the path, waiting, perhaps, for the luckless *chauffeur* to pay for its repair, which the owner threatens to make him do. It is a scandalous thing that people should be allowed to place such barriers on a road—which, by the way, leads to Coldharbour—like that we have mentioned, without being compelled to place some warning sign to assist strangers travelling at dusk. Riders journeying along the road in the dark are almost certain to run into the gate with more or less disastrous results.

Freights.

A GENTLEMAN recently resident in Banbury but now living in London leaves these shores for America next week, and in the course of conversation at the Automobile Club has been comparing the difference in freightage by train of his voiturette from the Midland town to London to the amount charged by an American company for the conveyance of his car from London to Philadelphia. In the first instance the charge was £4 19s.; and in the second, the American company collects and packs the car, clears—but does not pay the duty—the customs and delivers to Philadelphia for the sum of £6 10s.

The Motor-Car on the Battlefield.

ALTHOUGH the automobile was not allowed to play a part in the military operations in South Africa, there is little doubt it will be used ere long to visit some of the battlefields. In fact, such has already been done, Mr. F. G. Cartlidge, of Durban, having recently gone over all the battlefields in Natal on a Motor Manufacturing Company's motor-tricycle, geared very low. He recommends voiturettes of from 5 to 7 cwt., and about 5 or 6 h.p., as eminently suitable for touring there, and will be pleased to advise any motorists thinking of visiting South Africa with their cars.

Royal Motor Artillery.

THE suggestion made recently for the establishment of Royal Motor Artillery finds a supporter in the *Times of India*, which, after showing the useful service performed by traction engines in South Africa, says:—"It is certainly true that nowadays motor-cars have been driven at high speed over rough ground with astonishing success. The question of cost deserves examination. The average price of battery horses in England is set down at £50, so that a gun-team of six horses costs £300. The estimate of the cost of a high-speed motor engine capable of drawing any field gun is about £200, while the liability of loss is said to be far less. We do not profess to assert that the notion is feasible, but it is at least worth examination. The proposal is not weakened by the admitted fact that motor artillery could not be used in mountainous districts. Cavalry would be of no service in an attack on Gibraltar, but their utility in warfare is not rendered

doubtful thereby. Gunners who may be inclined to jeer at the suggestion ought to remember the opinions expressed by 'experts' when the breech-loading gun was first invented."

Volunteer Automobilists.

It is some time since a correspondent suggested the formation of a Volunteer motor-cyclists' corps—an idea which did not realise into fact. Now the success of the operations of the automobiles employed in the French military manoeuvres has led to a proposal for the establishment of a Volunteer Automobilists' Corps. The development of such a notion would be more difficult than that of the formation of a motor-cycle corps, but there is a modification of the idea which seems worthy of execution. Could not automobilists offer their cars to the officers at army manoeuvres for the purpose of carrying messages, etc.? Such a beginning would probably quicken the coming of the automobile into the Army.

A Curious Accident.

An extraordinary automobile accident is reported from Aix-les-Bains, and once again would it appear to be demonstrated that a special providence watches over the welfare of motor men. The mishap occurred on the 18th instant, between Lyons and Aix-les-Bains, at what is perhaps the most dangerous place of the route, known as Pont de l'Abime. Here the road skirts the river Sierroz, and a sheer drop of some thirty-five feet to the surface of the water makes the spot by no means a pleasant one. On the 18th instant, M. Chappuis, of Lyons, accompanied by Dr. Lochon and a servant, were driving slowly, *en route* for Aix-les-Bains, when at this spot a sudden side-slip on the greasy road precipitated the vehicle and its occupants into the river. Dr. Lochon suffered a broken leg, but the other two travellers escaped unscathed from what one would have considered to be certain death. Even the car showed but comparatively little sign of its terrible fall.

In a Fog.

A RUN of the Manchester Automobile Club was arranged for Saturday last to Buxton, but owing to the bad weather it was spoiled. The owners of eight cars had promised to attend and take dinner at the Shakespeare Hotel. But the morning opened so inauspiciously that the dinner was cancelled. Ultimately, Mr. J. H. Smith arrived at Buxton on a 5 h.p. phaeton, the only other car putting in an appearance being a 5 h.p. Marshall phaeton owned by Mr. Rupert Williamson, who was accompanied by a friend. Mr. Simpson, of Messrs. Simpson and Bodman, was there on his tricycle. The party had dinner together, and then Mr. Williamson went on to Bakewell, Mr. Smith setting off by the Cat and Fiddle to go through Macclesfield and Alderley home, by the route taken on the 1,000-mile Trial. About half a mile from Buxton Mr. Smith ran into a thick fog and had to cross by the Cat and Fiddle without being able to see more than a yard or two in front. The gradients on the road are very steep, and the many sudden turns of the road made it the more difficult. Fortunately Mr. Smith had a powerful Dietz lamp, and after leaving Macclesfield was able to make good running to Manchester.

Porlock Hill.

MOTORISTS have been much interested in the ascent of Porlock Hill on a Benz car as recorded in our columns last week, and Mr. S. F. Edge, who, of course, knows the gradient and surface of the hill, writes:—"Of course it is to a certain extent a question of gearing, as no doubt if a sufficiently low gear was used almost anything of any power at all could get up the hill, although possibly it might be necessary to make a periodical trip with a foot-rule to find out whether any progress had been made. Could the gentlemen who were present on the occasion of this car climbing the hill oblige us with the time occupied in climbing the hill and the average speed? Of course, although

the mere climbing of the hill by the 16-h.p. car was a great feat, nevertheless the most remarkable point about it was the speed at which it accomplished the journey. Did the Benz car carry two passengers up, and did it go up without a stop? It would certainly be interesting to have these particulars. No doubt all those who have seen the hill appreciate the difficulties in climbing it.'

New Motor-Tricycle Records.

It is a long time since any attacks were made upon records in Paris, and it has been left to Rigal to break what was becoming a distinctly monotonous quiet. The Parc des Princes was, as usual, the scene of operations, and the intrepid little rider simply slaughtered the previous best performances. His figures were:—One lap (666 mètres) in 31½ secs. (previous record 32½ secs.); 10 kilomètres in 8 mins. 25 secs.; 20 kilomètres in 16 mins. 16 secs. (previous record 16 mins. 47 secs.) The 20 kilomètre record has stood to Béconnais' credit since May 20th last, but Rigal's time is no less than 31 secs. faster, and represents a speed of 73 kil. 800 m. per hour. Perhaps now that the ball has been set rolling again we shall have as many of these speed trials as were formerly witnessed; indeed, it is fairly certain that Béconnais himself will not rest long without an attempt to regain his records.

MR. H. JOHNSON ON HIS "ESCALAPE" VOITURETTE.

Cuba Wants Motors.

ON some previous occasions we have referred to inquiries with regard to the use of automobiles on the sugar plantations. Now comes another confirmation of the demand that is arising in a letter received by a New York export house from a Cuban correspondent, who says there is a demand there for automobiles suitable for transporting cane on the plantations and to the grinding factories. At present the work is done with bull-carts, and is unsatisfactory. The larger plantations are equipped with railroads connected with the large grinding stations, but the smaller properties generally are less advantageously situated. It is from these that the demand for automobiles, it is thought, will be large if a suitable type can be constructed. The correspondent wrote that a planter of experience told him such a cart should be an ordinary platform affair, without sides, about seven feet broad, and the capacity about three tons of cane. The wheels should not be high, and the motive power should be steam. Extraordinary speed, of course, would not be a necessity, though ability to get over the ground with fair rapidity would be an advantage, since the wagons in that

event could be transformed into passenger carriages between crop seasons. The roads on the estates, he says, are fairly good, and flat iron wheels would obviate many difficulties. The need is for a strong machine, even at the expense of appearance.

**Unconventional
but
Descriptive.**

A LADY living in Sydney, New South Wales, thus gives her impressions of the motor-car:—"It is harmless to look at, but it seems to be restless when it has to stand still, and makes a low moaning all the time as if it felt bad inside. A large crowd gathered round it as we got in. The driver told us that here were five brakes, and that no accident could possibly occur unless twenty-five complications arose, and in addition somebody put a match to something; nevertheless, at first, we were too busy placing our trust in Providence to enjoy the novelty. The machinery of the motor is coiled up serpent-like beneath the seats, so that in addition to putting our trust above we had to place it below as well. No matter how fast the vehicle goes the motion never seems much to those inside. From the street it appears to skim along, out-distancing 'buses and electric trams; even the perspiring bicyclist with his head on a level with the front wheel is left behind by that little horseless victoria. As we moved along we seemed to have advanced a century ahead of the rest of the street; the horses had quite an antediluvian look, and the 'buses looked like Noah's Arks; the faces of riders and pedestrians flashed back on us admiringly till we felt as if we had invented the thing ourselves. The motor is an animal with many voices. Till you get on him he wails and jumps; once started he moves contentedly enough, only making a low continual grr-grr, which to the people outside has somewhat a cricket-like sound. When you want to move admiring people off the track you squeeze a squirt, and a horrible noise, something between a midnight cat and a foghorn, causes to fall under a tram a small boy who has just remarked 'Ere's a kerridge bolted from its 'orses.' The most original thing about the motor consists in the remark it makes to itself when you compel it to remain still for a minute or two. Its curses are low but deep. I don't know exactly how to work the cursing apparatus yet, but I am going to learn."

**Self-Propelled
Lunch Wagons.**

THE United States Lunch Wagon Company has been succeeded by the T. H. Buckley Company, of Worcester, Mass., which proposes to build self-propelled lunch wagons. So says an American correspondent, who evidently knows. Probably there is something peculiarly American in the institution of the lunch wagon in the United States. But, so far, it has not penetrated our British insularity. A self-propelled lunch would be a good thing if introduced into city restaurants as a means of quickening the mid-day feeding operations; send it round on a special wagon and even greater time would be saved. Motor-vehicles are now entering into the commissariat of the people, and, judging from the number of such ingenious applications recorded from America, we shall do most things by machinery before long. In those days the journalistic scribe will probably lay down his pen and by means of mechanism secure the transference of thoughts to paper without hand labour. Hurry along with those lunch wagons, and let both lunch and wagon be self-propelled.

**Coventry to
Manchester.**

THE query raised by Mr. J. Reginald Egerton in our issue of August 4th, with reference to the best road between Coventry and Manchester, brings a letter from Mr. Edgar Soames, of East Grinstead, who, as one who has had the misfortune to be misguided, as he was, by a modern though obsolete map, gladly replies to it. The old road no doubt lay through Coleshill, but that village is to be avoided, and the road to Tamworth taken, just outside Lichfield. Coventry will thus be gained by an entirely different route through Fillongley. This is a very fair road and Mr. Soames does not think it is any longer.

PARIS EXHIBITION NOTES.

(FROM OUR OWN CORRESPONDENT.)

(Continued from page 458.)

FOR the automobilist who is staying but a few days in the French capital, let me at once say that the Vincennes exhibition is not worth his while to visit. Most inconveniently situated and far removed from all other attractions, the unfortunate Annex contains but little of interest, so the visitor to Paris, who is at all pressed for time, may eliminate it from his programme with the certain knowledge that he loses little by so doing. To visit Vincennes one must devote an entire afternoon, for the journey is long and the means of communication very indifferent. And then there is so little to see. The collection of locomotives and rolling stock is certainly magnificent, and is well worth a prolonged visit, but apart from this section there is practically nothing of interest. The automobiles, for whose benefit the Annex was principally organised, cannot by any manner of means be considered the *élite* of horseless vehicles, and the firms exhibiting would appear to have lost all interest in the exhibition long ago, even if they ever had any. And the lack of interest displayed by manufacturers is not to be wondered at, for they do not exhibit for mere pleasure, and business has always been conspicuous at Vincennes by its absence. When any people do visit the show—and there are a fair number every Sunday and Thursday—they are not of the automobile buying class, and the folly of holding an exhibition of such an *article de luxe* as the motor-car in a district like Vincennes has long ago been made apparent. In London one would hardly select Wandsworth Common in preference to Hyde Park for the purpose of holding an automobile exhibition, but here in Paris the Bois de Vincennes was chosen instead of the Bois de Boulogne, and the result was inevitable from the very date of the selection. If the sole idea of the authorities was to give the East-enders of Paris a share of the big exhibition, that object has been attained, but at the sacrifice of the interests of the exhibitors. The moneyed class cannot reasonably be expected to trail across Paris to see automobiles, when right at their own West end are to be found the magnificent displays made by Charron, Moutier, and the Palais de l'Automobile. Had the Bois de Boulogne been selected, this year's automobile show would have scored an immense success, for the fashionable quarters in the vicinity of the Bois have throughout the year been crowded to repletion. All that Vincennes offers in the way of space could have easily been secured in the Bois de Boulogne, and the demonstrating cars would never have lacked for wealthy passengers during their trial trips. No, automobile constructors have no great reason to be satisfied with their share of the Exposition Universelle de 1900, for their expenses have been heavy and their returns microscopical.

But with time at one's disposition a visit to Vincennes can be made with pleasure, for I am sure that all motor men will examine with interest the splendid locomotives and rolling stock which have been gathered together from the four corners of Europe, and this will compensate them in some degree for the lack of automobiles. So to the man of leisure I will dictate my remarks; and first of all let me recommend him to pay his visit on a Thursday, when the Annex is usually seen at its best. It is on every Sunday and Thursday that fêtes are held, and while on the former the crowd is too numerous and frequently very mixed, the latter day usually witnesses a sufficient number of people to take off the miserably deserted appearance presented by the show during the remainder of the week. And then, too, some little gaiety is shown, and one often sees automobile racing on the part of voituresses and motor-cycles, the road running round the beautiful Lac Daumesnil being roped in and utilised as a track for these contests. So then I first of all recommend Thursday for the day of the expedition, and now will tell you how to get there. All routes are more or less bad, and for the visitor located anywhere in the centre of Paris the least so is the Metropolitan Railway. This line has only been recently opened, and it runs from the Porte Maillot, by way of the Place de la Concorde, Rue de Rivoli, Place de la Bastille, and Place de la Nation, to the Cours de Vincennes, practically a

straight line from end to end. Stations are found throughout the route at frequent intervals, and as electricity is the power used and the carriages and all appointments are beautifully clean and fresh, no more agreeable means of locomotion can be desired. The only drawback is the distance at which the Vincennes station is placed from the exhibition. Certainly there is a tramcar which runs from the railway terminus to the Porte Reuilly entrance of the show, but it is a tedious affair and usually densely crowded on fêtes. But the Metropolitan is certainly the best and quickest route to follow, and personally I always make use of it when visiting Vincennes. The fares are 25 centimes first, and 15 centimes second class, irrespective of distance. Upon descending at the Cours de Vincennes, the tramcar, a yellow one—is found just in front of the station exit, and for 25 centimes one is taken to the exhibition. The route follows the fortifications to the right, passing the Portes de St. Mandé, de Montempoivre and de Picpus until the Porte de Reuilly is

route branches to right and left, follow the right-hand one—the route de la Croix Rouge—and after some five minutes' walk one arrives at the road skirting the Lac Daumesnil. Here turn to the right, and bear again to the right where the route branches. This brings one direct to the automobile section, and one remarks at once on the left a building reserved for the products of MM. De Dion and Bouton. Here, holding the place of honour, are to be seen the three winning tricycles of the Paris-Toulouse-Paris race. It will be remembered that this *course* was 1,446 kilomètres in length, and that the three men who occupied the leading places were:—

1. Teste	23h. 54m.	1s.,	average per hour	56 kil. 400
2. Collignon...	27h. 28m. 34s.,	" "	" "	49 " 100
3. Bardin	30h. 0m. 26s.,	" "	" "	46 " 900

The three machines present a weather-stained appearance and carry a great assortment of spare parts, tools and accessories.

THE PRINCE OF WALES ON THE SERFOLLET STEAM CAR.—THE ROYAL "CHAUFFEUR" DONS THE GOGGLES.
(Cliché de) (La France Automobile.)

reached, when one should turn to the left. The exhibition gates will then be seen directly in front. Should the intending visitor find himself in the neighbourhood of the Ceinture Railway he cannot do better than travel by it to the Rue Claude Decaen, the nearest station to the show. Starting from the Gare du Nord, for example, one takes about forty minutes to make the journey on this line, no fewer than ten stations being passed *en route*. The second class single fare is 30 centimes, and trains leave frequently from the east end of the station. Upon descending at the Rue Claude Decaen, turn to the right and pass by the Porte Reuilly to the exhibition. Other means of communication, which convey one to within a reasonable distance of the show, are the tramways Louvre—Cours de Vincennes, Place de la République—Charenton, and Place de la Bastille—Charenton. By boat one should descend at the Ponton des Carrières, but none of these routes convey one very near to the Exhibition.

Once having passed through the exhibition gates at the Porte Reuilly, one should proceed straight ahead until the

Placed on either side of them are a couple of the new type voiturettes, fitted with straight rear axles and new speed change levers. Both are four-seated cars, and one carries an awning. A couple of quadricycles and a like number of tricycles call for no particular attention, but the two ancient steam cars are of particular interest. The first was built in 1885, and carries both boiler and engine in front, the power developed being about 6 h.p. The second, constructed a year later, carries a 10 h.p. engine, placed with the boiler in the middle of the vehicle. Modern steam vehicles, constructed by the Puteaux house, are represented by a large 30-h.p. omnibus and a 25-h.p. lorry. Samples of the firm's $3\frac{1}{2}$ h.p. water-cooled and $2\frac{1}{4}$ and $2\frac{3}{4}$ h.p. air-cooled motors are also shown.

(To be continued.)

THE Desheron Motor-Car Company, of New York, expect to have a four-ton steam truck in regular service in October next.

THE HENRIOD VOITURETTE.

A NEW voiturette, of which illustrations are given here-with, has lately been completed by Mr. C. E. Henriod, of Neuilly, France. At first sight, the vehicle closely resembles the well-known De Dion voiturette, but it will be

FIGS. 1. AND 2.—PLAN AND ELEVATION OF HENRIOD VOITURETTE.

seen from the drawings that the general arrangement of the motor and transmission gear is entirely different. The motor is of the vertical single-cylinder type, and is said to develop $5\frac{1}{2}$ h.p. It is provided with electrical ignition, and is, states *La Locomo-*

FIG. 3.—FRONT VIEW OF HENRIOD VOITURETTE.

tion Automobile, air-cooled in a special manner. Three speeds, ranging from 10 to 45 kilometres per hour, and a reverse motion are provided. The engine is located in the fore part of the frame, under the front seat. Interposed between the motor and the

longitudinal shaft *O* is a friction clutch *V*, which permits the motor to be instantly cut out from the transmission gear. The variable speed gear, which is enclosed in the box *C*, consists of a train of spur wheels meshing with corresponding pinions on a short parallel shaft. The latter transmits its power to the rear "live" axle by means of bevel gearing. The frame is of tubular construction, and is spring-suspended on the axles, both back and front. The motor and gear being entirely supported by the frame, any type of body—voiturette, coupé, delivery van, etc.—can be fitted thereto. In the four-seated car illustrated the front seat is reversible, so that all four riders can face the direction of progression if desired. The usual brakes are provided, viz., band brake acting on the hubs of the rear wheels, and a similar brake on the longitudinal shaft *O*, which it will be noticed is provided with universal joints.

THE "CHAUFFEUR."

THE International Motor-Car Company have lately supplied a motor dog-cart to the Right Hon. Lord Edward Spencer Churchill.

IN a local timetable we have observed an advertisement headed "Headquarters, Automobile Club." The announcement referred to the Reindeer Hotel, Milcheapeen Street, Worcester.

ON the exterior of the Transportation Building at the Paris Exhibition are a series of decorative figures symbolical of various industrial pursuits and pastimes. Among these is the figure—reproduced above—of the *Chauffeur*—in all the glory of special raiment suitable for automobile touring.

MR. VAN RADEN, Ellys Road, Coventry, in addition to his now well-known glass accumulators, has placed on the market a new induction coil, which is made in two sizes, the larger for motors up to 700 revolutions per minute, and the smaller for engines running above that speed. Both coils give a powerful fat flaming spark with very low consumption of current.

THE British Power, Traction, and Lighting Company, Ltd., has just been registered with a capital of £52,000, to acquire the businesses of the Engineer Cycle Works, Ltd., the Eclipse Brass and Copper Company, Ltd., the Anglo-American Motor Car Manufacturing Company, and the Power Transmission and Traction Company, all of Hull Road, York, to take over from the liquidator the assets of the Disc Hub and Components Company, Ltd., and to carry on the business of motor, motor-car, crane, lift, and cycle manufacturers, etc.

MOTOR-CARS ON THE CONTINENT.

(From Our Own Correspondent.)

Motor-Vehicles in the French Postal Service.

In a few months it is expected that postal motor-cars will be a feature of the Paris streets. M. Mougeot, who has already been identified with many useful improvements at the French General Post Office, is studying a plan for the utilisation of electrically-worked cars or voiturettes for the speedy distribution of letters and telegrams. The cars are to have four wheels, and will be in appearance something like the tricycles used by many tradesmen for the delivery of goods.

Leipzig Exhibition.

LIEPZIG is to have its automobile exhibition, and this, too, on no small scale, for every effort is being made to render the show of as international a character as possible, and to demonstrate to visitors that the industry, although but young in years, has already passed out of the stage of infancy. Friday, October 19th, has been selected as the date of the opening ceremony, and the exhibition will close its doors upon the evening of the following Tuesday. Automobilmism is progressing apace in Germany, and this exhibition has aroused the greatest interest throughout the country. While it is hardly probable that many foreign firms will be induced to exhibit, one may safely assume that all the leading German houses will be represented.

Racing at Lyons.

In spite of all doubts to the contrary, the Motor Club of Lyons ultimately received the necessary authorisation to hold their proposed race from Lissieu to Mâcon and back, a distance of one hundred kilometres, and the event was duly decided last week. A great number of local automobilists had sent in their names for one or other of the three categories provided, and in the big car class the vehicles entered were all extremely powerful, ranging as they did from twelve to thirty-two horse-power. But as is so often the case the most powerful car did not prove itself to be the most reliable, and the first place was secured by M. and Mme. Oillion, who were competing with a 12-h.p. racer. M. Pansu (16-h.p.) and M. Audibert (32-h.p.) finished second and third respectively. In the voiturette class M. Collin, the president of the local club, was successful in securing second place, the actual winner being M. Archinard, who drove a 3-h.p. car. Among the motor-cyclists, Berthet proved successful, and was followed home by Jacob and Rival in the order named. The course was followed by a banquet, which was largely attended.

For Electromobilists.

SOME time ago I mentioned in these columns that the Touring Club had in course of preparation a map of France especially designed for owners of electric vehicles, and I am now able to give some indications of the progress made. To-day, thanks to the efforts of the T.C.F., the electromobilist can set out on ten distinct itineraries with the certain knowledge that he will be able to recharge his accumulator every hundred kilometres. These itineraries are:—1. Paris to Lille; 2. Paris to Givet; 3. Paris to Belfort; 4. Paris to Dijon; 5. Paris to Auxerre; 6. Paris to Saint Nazaire (Escoublac); 7. Paris to Brest (by the Côte Bretonne); 8. Paris to Caen; 9. Paris to Havre; 10. Paris to Dieppe. It is anticipated that in some eight months the work will have been completed, and that a great number of routes will have been traced throughout the country. As time progresses the preparation should be facilitated, for with the improvements so continually being made the electromobile's field of action should widen accordingly, and whereas to-day the compilers of this work must select their itineraries on the basis of a hundred kilometre run as

a maximum, in a few months' time they should be in a position to calculate the energies of the electric vehicle at one hundred and fifty kilometres. Electromobilists should be infinitely grateful to the T.C.F., for already they have the option of ten capital itineraries and the comforting assurance that the efforts of a great and powerful organisation are at work to further their interests. Founded for cyclists, the T.C.F. never hesitates to extend its field of action when a demand is made upon its services, and touring automobilists have to thank it quite as much as the A.C.F. for many of the privileges which they enjoy. It is interesting to learn that upon August 1st last the number of members enrolled upon the books of the T.C.F. was 73,433, a unique record among the world's clubs, I should fancy.

An Italian Voiturette.

MESSRS. MAROCCHI BROS., of Milan, Italy, have recently introduced the little voiturette herewith illustrated. The vehicle is a three-wheeled affair, having seating accommodation for two persons side by side. As will be seen, the single

front wheel serves the double purpose of steering and driving. The car illustrated is fitted with two motors, each of 1½ h.p., one at each side of the front wheel. The motor is of the air-cooled type, and is provided with electric ignition and Longuemare car-

burettor. The speed of the car is controlled through the motor, no variable speed gear being fitted. Messrs. Marocchi claim that the double-engine car can attain a speed of 30 kilometres per hour. They are also making a similar vehicle fitted with a single 1½ h.p. motor, for which a speed of 20 kilometres per hour is claimed. The makers state that they have brought out the little vehicle, which has been named the Aquila, with the view of meeting the demand for a cheap but reliable automobile.

The Siemens and Halske Electrical Omnibus.

MESSRS. SIEMENS AND HALSKE, one of the leading electrical engineering concerns in Germany, have for some time had an electric omnibus, very much on the lines of the Lombard-Gerin described in the last issue of the *Journal*, in service in Berlin. The Siemens and Halske electrical omnibus is adapted to run by current from its own batteries or by current taken from an overhead trolley. The batteries may also be charged from the trolley wire. The 'bus has an extra pair of wheels just forward of the front driving wheels, which act as guide wheels to keep the omnibus on the line when running as a trolley car. As soon as the omnibus leaves the track, these wheels are raised from the ground and the trolley is tied down. The steering gear is of the usual kind, but fitted with ball bearings, and is capable of turning the omnibus in a very narrow street. The brakes are of the ordinary shoe variety, and in addition there is an electric emergency brake. Four motors of 4 h.p. each are used. The total weight is about seven tons, of which the batteries are responsible for 3,300 pounds. The chief value claimed for this combined vehicle is that it can be used in connection with a tramway system for a route, a part of which runs through streets too narrow for tram lines, or on which they may be prohibited for other reasons.

Voiturette Gymkhana.

It is announced that *Le Sport Universel Illustré* intends to repeat the voiturette fête and gymkhana, as organised last autumn at the Rond Point de Longchamp. The selected date is Saturday, October 20th, and the profits accruing will be handed over to the poor of Paris. The idea is excellent, but if the fête is to secure the success which all automobilists will wish it, steps must be taken to render the organisation more perfect than it was last year. Upon that occasion the meet was noteworthy for extreme unpunctuality, and as any number of the privileged public were permitted to promenade within the enclosed space, those behind the railings saw but little or nothing of several events. With good management a fête in the Bois is certain to command a great success, for there will be no lack of people in Paris, and the beauty of the woods alone at that time of the year is always sufficient to attract. The programme will be announced at an early date.

THE HENSCHEL ELECTRICAL VEHICLES.

REFERENCE has previously been made in these columns to the electrical vehicles of the Berliner Maschinenfabrik (Henschel and Company), of Charlottenburg, Berlin. We are now able to illustrate several types of electromobiles lately turned out by this concern. Fig. 1 shows a droschke capable of seating two or four persons exclusive of the driver. The car can, it is claimed, traverse a distance of 50 kilometres on one charge of the batteries; it represents a type which is being used in Berlin as a public conveyance in

FIG 1.—THE HENSCHEL ELECTRICAL DROSCHKE.

competition with the horse-drawn cabs. Messrs. Henschel claim that where facilities are at hand for the charging of the batteries their cars can be run at a daily cost much less than that of horse-drawn vehicles.

FIG 2.—THE HENSCHEL PHAETON.

Fig. 2 shows a neat, two-seated Phaeton, which is claimed to be well adapted for doctors' use. The electro-motor in this vehicle is fitted about the centre of the frame, and is

connected by a flexible shaft and bevel gearing to the rear axle. The battery of accumulators, which are of the Hagen type, is stated to have a capacity sufficient for a run of from 30 to 70 kilometres on one charge, according to the roads traversed. It is carried in a receptacle at the rear in such a way that the discharged battery can be withdrawn and a fully-charged set substituted in from two to three minutes. The

FIG. 3.—THE HENSCHEL DELIVERY VAN.

construction of delivery vans propelled by electricity has also been taken up by the Henschel Company, one type being illustrated above in Fig. 3. A feature of the Henschel vehicles is the combination of the steering handle and the speed controller. The steering standard is hollow and encircles a flexible shaft which is connected with the controller switch.

THE Capital City Automobile Company has been incorporated at Washington, U.S.A., with a capital of £20,000.

HITHERTO it has been necessary for automobilists to obtain a license to drive a steam car in New York. One of the city magistrates has, however, just given a decision to the effect that no licence is necessary if the car is of less than 10 h.p.

MR. A. SIMPSON, motor-car proprietor, was sued in the Ipswich County Court last week by Mr. W. Cooper to recover £8, alleged damages. Plaintiff stated that defendant's car smashed the rear wheel of his cart on the Derby Road. His Honour thought there was fault on both sides, and gave judgment for plaintiff for £2 10s.

MESSRS. MALICET AND BLIN, of Aubervilliers, France, have lately introduced a worm and wheel reduction for steering gears. This appliance is intended for use in connection with a steering hand-wheel and an inclined shaft. A worm, keyed to the steering shaft, engages with a worm-wheel sector. On the shaft of the worm-wheel sector, outside the case, is keyed a one-armed lever, which connects to a lever arm on one of the steering spindles. The gears are enclosed in an aluminium case, which is also filled with heavy grease. This case may be placed either inside the body or below it. The worm has four threads, cut either right-handedly or left-handedly.

THE Crest Manufacturing Company, of Cambridgeport, Mass., whose Duplex motor has already been referred to in these columns, have recently brought out a new type of single air-cooled cylinder petrol motor, rated at $2\frac{1}{2}$ h.p., for tricycles and quadricycles. The heads, cylinders, crank-cases, pistons and rings are stated to be cast from steel for the greatest possible strength and lightness. The pistons and rings are ground, and the hardened steel crank pins and shafts are brought to size in the same manner. The flywheels, which are inside the crank case, and constitute nearly half the weight of the motor, are the only cast iron parts. The crank case is split horizontally instead of vertically, thus enabling the shaft, flywheels, rod and piston to be quickly removed for inspection, without taking down any of the piping. No compression cock is used, the exhaust valve being lifted instead, and one handle controls both this appliance (when starting) and the subsequent lead of the ignition.

THE CANELLO-DURKOPP MOTOR-CAR.

IN our issue of February 23rd last we published a detailed description of the Canello-Durkopp car, which, while closely following the lines of the Panhard type of vehicle, comprises some special features. The car, which is becoming very popular in Germany—one being used by the Empress Frederick—has recently been introduced into this country by the British and Colonial Motor-car Co., of 14, Baker Street, London, W. The standard type of car is fitted with a 8-h.p. two-cylinder vertical motor. The engine is located under a bonnet at the front, the carburettor being of aluminium, and of the Phenix float-feed type. The variable speed gear, which is enclosed in an aluminium box, is adapted to give four speeds forward—six, twelve, eighteen, and twenty-four miles per hour, and a reverse motion. The special feature of the car is the water-cooling tank carried in the fore part of the frame. It takes the form of a metal tank 1ft. 10in. deep, 1ft. 6in. wide, and 5in. deep, between the sides of which are set 1,200 tubes, one-quarter inch bore, through which air is drawn by a large helical fan running on an extension of the motor-shaft. The temperature of the heated water from the cylinder water jacket is rapidly reduced in passing through this radiator, whence it is returned to the tank by means of a centrifugal pump. Wheel steering is fitted, while three brakes are available, two hand brakes on the hubs of the rear road wheels applied in the usual way by a hand lever, and a positive grip brake on the countershaft. The British and Colonial Company hope to receive a 16-h.p. 4-cylinder car of this type within a few days, and we understand that Mr. J. H. Adams, the managing director, intends to enter and drive it in the next quarterly 100-mile trial of the Automobile Club.

GENERAL VIEW OF THE CANELLO-DURKOPP 8 H.P. PHAETON.

THE Federation of French Automobile

Artificers and Conductors is this week holding a congress at the Bourse du Travail in Paris, to discuss labour questions.

AT the North Shields Police Court, last week, Henry Luttart, Newcastle, was fined 10s. and costs for driving a motor-car on the wrong side of the road on the Grand Parade at Tynemouth.

THE Kaiser's Daimler car has been damaged, and has been sent for repairs to Cannstatt. It served well during the manoeuvres, but the other day, near Cadinen, in West Prussia, it upset in going uphill, and was damaged.

THE French automobile industry is likely to receive further impetus as the result of the experiments made at the recent manoeuvres. An officer of high rank states that the vehicles were useful beyond all expectations, and the artillery has already decided to supply with motors certain carriages used in the transport of baggage and ammunition.

IN the report of the Superintendent of Cleansing of the Glasgow Corporation for the year ending May, 1900, it is stated that a deputation representing the Cleansing Committee attended important trials of motor-vehicles for heavy traffic, held in Liverpool in July, 1899, under the auspices of the Liverpool Self-propelled Traffic Association, and that the results of the trials proved conclusively that motor-wagons are well suited for heavy traffic, and entirely justified their adoption in connection with the removal of city refuse.

MOTOR-CAR TRIP.

FROM NOTTINGHAM TO NEWARK.

MANY who have for a long time been rather sceptical as to the advantages of motor-vehicles are beginning to freely admit that they form one of the most pleasant means of locomotion hitherto adopted. Recently it has become popular in Nottingham, and there seems to be still a wider field of popularity for it in the future. The formation of the Universal Motor-Car Company in Nottingham is a step in that direction. Although the company has only been inaugurated a short time, it has already established a car service from the Theatre Royal, Nottingham, to the Round House at Wilford, which, during the few days it has been in operation, has been exceedingly well patronised. The main object, however, of the company is to afford better facilities to people living in the city to visit nature's beauty spots in the surrounding districts, and trial trips are being arranged to Lincoln, Matlock, Dovedale, Newark, and other places of special interest. One day last week, for instance, one of the cars travelled to Newark, conveying a party of eight, including the manager of the company, Mr. J. B. Sheldon. The party started from the Clarendon Hotel about three o'clock, and the route taken was through Carlton, Burton Joyce, Oxtun,

Fiskerton, and Kelham. It was a delightful ride, and at no point did the passengers have to dismount, for the car was equal to carry its freight safely either up hill or down dale. On the way many lovely glimpses of nature charmed the eye, and as one passed village after village in quick succession, viewing here and there the silvery Trent wending its way onward, ever onward, towards the sea, gazing upon its fertile valley, rich in autumnal tints and luxuriant vegetation, also occasionally obtaining a peep at ancient churches nestling in the bosom of a

cluster of trees, the ride became increasingly enjoyable. Another feature, which caused some amusement to the passengers, was the startled appearance of some, and the intense eagerness manifested by others of the rustics at the sight of the horseless car. Tea being taken, a visit was afterwards paid to the historic castle in the town. On leaving Newark the car went at a good speed, which was maintained until the welcome lights of the city of Nottingham burst upon one's vision. No hitch occurred on the return journey, which was made in an hour and twenty minutes.

ONE of the Thames Valley Motor Company's wagonettes had a collision near New Cross the other day, and was severely damaged.

THE *Horseless Age* states that Mr. E. C. Stearns, vice-president of the Anglo-American Rapid Vehicle Company, of New York, has secured all the American rights of the said company, and will manufacture under their patents. He has secured the Frontenac and Barnes plants in Syracuse, and organised the Stearns Automobile Company, with a capital of £200,000.

MESSRS. R. SCAIFE AND Co. have now got into their new premises at the Reliance Motor Works, Armley Road, Leeds. They have a staff of experienced workmen and a good plant of machinery, and are in a position to undertake any description of motor work. The works are within three minutes' walk of Holbeck station.

SOME NEW VARIABLE-SPEED GEARS.

SEVERAL variable speed gears, the feature of which is the employment of expanding and contracting pulleys, have already been described in these columns. The latest device of the kind is of French origin and is due to Messrs. Waché and Krieger. The apparatus, which is on view at the Paris Exhibition, consists of a pair of expanding pulleys, each capable of varying its effective diameter in the ratio of 2 to 1. The arrangement (Figs. 1 and 2) only differs from other similar devices in details. V and V' are the two shafts, the one driving and the other being driven, upon which are mounted two expanding lattice-work pulleys. Six arms are pivoted upon a spider which is keyed to each shaft; these arms are provided at one end with a toothed quadrant, which gears with a circular rack mounted on a feather-key upon the shaft, and at the other end with a curved slot, through which pins connected to the pulley lattice pass. A hand wheel is mounted upon a shaft which carries, at either end, a gear wheel working into a circular rack; this rack is connected by a sleeve with the circular rack previously mentioned. The

FIG. 1.

FIG. 2.

action of the gear is clearly seen from the illustrations; by rotating the wheel, in one direction or the other, the one pulley is caused to expand and the other to contract, and *vice versa*, and thus the relative speed of the two shafts, A and B, can be varied in the ratio of 4 to 1.

There is also exhibited at the Paris Exhibition another system of extensible pulleys by M. R. De Montais, of Beauvoir (Eure et Loire). The hubs of the pulleys are in two parts, and by approaching or withdrawing these two parts from each other the diameter of the wheels is increased and decreased respectively. The two hub parts of one of the pulleys are regulated by turning a shaft with a right and left thread. The diameter of the other pulley is varied automatically by the tension of the belt, and by springs. The springs on the shaft tend to increase the diameter of the pulley, which latter is limited by the length of the belt.

FROM January 1st to August 30th this year no fewer than 1,500 licences were issued for motor-cars of various descriptions in Belgium,

AN AMERICAN AUTOMOBILIST'S OPINION OF PETROL AND STEAM MOTOR-CARS.

MR. GEORGE F. CHAMBERLIN, vice-president of the Automobile Club of America, has in turn owned and operated both petrol and steam motor-cars. In the recent run of the members of the club to Philadelphia he made the best-recorded time with one of the former. He is one of the most experienced *chauffeurs* in America, and has driven vehicles of these two types over thousands of miles of country roads. Comparisons are not always invidious, and Mr. Chamberlin's brief summarisation of the advantages and disadvantages of each type may be of service to those who are interested in the vehicle which, it is prophesied, will be a distinctive feature of the travel and traffic of the next century.

"The petrol car has, in my opinion, a few advantages over the steam, although I think the latter style of machine is preferable for heavy work, and the field of one is just as wide as that of the other. Where the petrol vehicle excels is not in strength or durability, but in small details. In the first place it has no steam boiler and no fire in connection with its driving mechanism. The motive force is supplied by a simple engine, and there are no water, steam, or air gauges to watch, or to be shattered in rough going. The petrol car is, consequently, capable of a much quicker start, as it is not necessary to get up steam, and no care to keep it up during stops is needed. On the score of safety there is little difference, as the number of safety appliances render the possibility of an explosion in the steam carriage a very remote possibility, and the ridiculous ordinance requiring a user of this type of vehicle to take out an engineer's license is no more needed than one requiring the same of the driver of any other type of machine.

"Compared with the electric vehicle, the radius of action of either steam or petrol cars is much greater. One charge of petrol will last for a long trip, the ordinary use being about five gallons for every 100 miles. The economy of running is also much greater. At the present price of petrol, the cost of running a car is about a farthing a mile. The ease with which petrol is procured, and the distance to which one charge will carry the vehicle, makes it pre-eminently a touring carriage, and constitutes its chief advantage over the electric.

"There are, however, some disadvantages connected with the petrol vehicle. One is the necessity of starting the carriage by hand, requiring considerable muscular effort. There is more or less vibration from the pulsations of the piston, and while this is not particularly noticeable when the machine is in motion, it becomes exceedingly unpleasant when it is at a standstill. Another objection, which is common to all explosive engines, is a slight odour of petrol, noticeable under certain weather conditions. The chief disadvantage, however, is the difficulty of controlling the speed of the engine, not the vehicle. That may be stopped almost instantly by throwing off the clutch and applying the brake, but it takes longer to diminish the speed with which the engine is working.

"There are three important points to be looked to when running a petrol car. First, that the ignition is uniform; otherwise the vibration of the engine will be irregular and very annoying, and will cause the vehicle to make sudden stops and starts. Fuel is the next important point. It is not pleasant to find the petrol tank empty and the machine at a standstill at sunset on some lonely country road. It is easy to procure petrol, however, at almost every village, and I have never experienced any inconvenience from lack of it. Lastly, the speed gear should be carefully adjusted, and, above all, thoroughly lubricated. On a long trip it is easy to create hot bearings, and that means an hour or more of annoyance and delay. The best gear for road work is that by which a maximum speed of eighteen to twenty miles is attained."

DR. DAWSON TURNER, of Edinburgh, is disposing of his well known 10-h.p. Delahaye phaeton.

HERE AND THERE.

At Grimsby, at the latter end of last week, I discovered that the tramway service is about as irritating a so-called public convenience as any I know. Between that fishing town and the pleasant little seaside resort of Cleethorpes is enough traffic to demand a decent, orderly and regular service. There are trams which crawl along and sometimes run off the lines, and there are dozens of wretched wagonettes with drivers who seem disposed to drive hard bargains with strangers. But, alas! the jolting and the jumping that is caused by those fearful vehicles is sufficient to cause one to stay away from the district altogether. An electric tram service will probably be opened next season, but there is certainly a chance of success for one or two motor-vehicles, which might be profitably employed to ply between Cleethorpes and the few interesting villages in the vicinity. Those concerned in the development of motor-car services should make a personal study of the local conditions.

ONE thing that has somewhat damped the enthusiasm of motor-vehicle advocates at the seaside has been the tendency on the part of some drivers to "show off" the points of their

ON the Thames Ironworks track, at Canning Town, Mr. C. Jarrott has been having some preliminary trials prior to his attempt on the hour record. Mounted on his 6-h.p. racing De Dion tricycle he broke the five and ten miles motor-tricycle record, covering the former distance in 7 mins. 22 $\frac{1}{2}$ secs., and the ten miles in 14 mins. 48 $\frac{3}{4}$ secs. Mr. F. T. Bidlake took the times, which would probably have been even better but for the high wind prevailing at the time.

POETS are dangerous, and often libellous people. They seem to keep such a person in the office of the *Bournemouth Guardian*, for he has just written some rhyming jingle on the progress of the motor-car. The following specimens will suffice—full quotation might be painful.

Belching and wheezing and gurgling and groaning,
Hiccoughing, coughing and spitting and moaning,
Hissing and screeching and tottering and shaking,
Booming and pounding and staggering and quaking,
With a rumble and roar and a thousand things more,
And the smell of petroleum all the road o'er,
With a clatter and bang and a hoot on the horn,
And that's how the motor goes down into Bourne.

FIG. 1.—GENERAL VIEW OF ROCHET MOTOR-TRICYCLE. (For description see next page.)

machines by going as near to the kerb as possible, running close to pedestrians, and similar antics, which sensible people do not care about. I hear that some feeling has been caused at certain places on the north-east coast owing to this silliness. Certainly the proprietors of services should be very explicit in their instructions to drivers.

THE movement among motor-car manufacturers in the direction of appointing official repairers of their machines in every district is growing, and the Motor Manufacturing Company, Limited, is now willing to consider applications for such appointments. There is no doubt that engineers in the provinces—particularly those whose works are on the main country roads—will find it to their great advantage to become well acquainted with the technical details of the automobile. That many are already studying the matter with a view of getting practical knowledge of the various types of cars, etc., is proved by the subscription list to the *Motor-Car Journal*. Mention of the Motor Manufacturing Company reminds me that the Daimler-Hampton char-a-banc at Brighton, to which I referred last week, is one of their cars.

I LEARN that the De Dion-Bouton Syndicate have received more than a hundred applications for the appointment of official repairers.

IN connection with previous remarks as to the advisability of running motor-cars in connection with train services, I learn that the Newport Pagnell Motor-car Company make a connection between the London and North-Western Railway at Newport Pagnell and the Midland Railway at Olney, passing through two villages on the journey. Commercial travellers find this service to and from Bedford an excellent one, as they can get there in an hour—half an hour on the motor-car and thence by train. This is much cheaper than the train journey by the London and North-Western Railway, which takes two hours or more. The Newport Pagnell Motor-car Company have now been running motor-car services nearly two years—making five journeys daily during the summer and four during the winter months. During all this time they have never had to suspend the service through actual breakdowns.

ESSEX is getting an unenviable name among motorists because of the discussions on speeds which take place so frequently at its local boards, and even at the county council. These, however, are not deterring many would-be purchasers of motor-cars, and hardly a week passes without some new automobile enterprise being announced. Among Essex firms who are pushing the motor-car business, Messrs. J. Green and Co., of Loughton, are favourably situated and able to offer good assistance to all touring in Epping Forest.

MR. A. J. BALFOUR takes all his pastimes seriously, and the close attention he gave to the intricacies of golf until he attained distinction in the game was being given to the motor-car until the General Election upset all calculations. He was enjoying himself immensely in Haddingtonshire before going to his election campaign in Manchester, and journeying to and from the golf links on his voiturette. His sister, Miss Balfour, is quite as enamoured of the automobile as her brother, and will probably soon become an expert motorist. Probably, when the excitement and strain of his campaign is over, Mr. Balfour will brace himself for more political work by a week or two's tour by motor-car in Scotland.

MESSRS. R. COLES AND Co., of Bedford, Middlesex, are keen motorists, and a party of four from the firm have had a run on their last new car, which also carried the necessary luggage. In five days 500 miles were covered, the route being from London to Yeovil, Exeter, Plymouth, Bristol, and home again. Truly a capital trip, and one made all the more pleasant by the fact that the car gave no trouble whatever.

PUSHING the motor-car business in the provinces is no easy matter owing to the keen prejudice that exists. Every little mishap to a car is magnified, whereas accidents to horse-drawn vehicles are usually ignored or regarded as commonplace. I have just heard of a firm trying to establish a motor business and only getting the first order after six months' running about the district. Certainly the locality was quite a new one for the industry; but this illustrates the uphill work that is essential to ultimate success. But when there are half-a-dozen motor-vehicles privately owned in a town they quickly dispel the illusion as to their uncertainty which impractical people seem fond of entertaining. My correspondent, who has just made his first motor-car sale, will have to continue his enterprising methods—and I shall be glad to have news of further developments in his district.

LOLLIUS.

THE Discount Motor-Car Company, of 145, Euston Road, London, are arranging to act as agents for the sale of second hand motor-cars, and in connection therewith are about to issue a little publication to be known as *The Motor Mart*, giving particulars of cars for sale. The first number of the new list will be issued on the 1st prox.

AN American automobilist has lately devised a water-level indicator for use in connection with the water tanks in Locomobile steam cars. The *Scientific American* thus describes the device:—"To the longer leg of a brass rod, bent at right angles, a brass float is secured which rises and falls with the water in the tank. The short leg of the rod passes through a brass sleeve which bridges the space between the carriage body and the tank, and which is held in place by a nut screwing upon the threaded end of the sleeve. The short leg of the rod projects from the sleeve, and its squared outer end receives a finger or pointer which plays over a scale graduated in gallons. As the float falls in the tank, the pointer is turned a corresponding distance and indicates on the scale the number of gallons of water still left in the tank. The float consists merely of an ordinary brass box, 1½ inch in diameter at the ends and 1¼ inch high, the cover being soldered to the body to form an air-tight joint. The brass rod is likewise soldered to the box. It will be observed that all the parts, including the sleeve, are made of brass to resist the action of the water. The pointer is made preferably removable, so that it can be detached whenever it is found that the float is not absolutely air-tight.

THE ROCHET MOTOR-TRICYCLE.

THERE are several new features in the latest model of motor-tricycles made by La Compagnie Générale des Cycles et Automobiles (Rochet-Petit), of Paris, so that the following brief description may not be without interest. Either a motor of the De Dion or Automoto type is fitted as desired. Fig. 2 shows a section of the carburettor which is now being used with the engine. The device is very similar in general respects to the well-known Longuemare, but combines the "spray" and the "constant level" systems. The petrol flows from the tank by the pipe *T* through a metal

FIG. 2.—SECTION OF ROCHET CARBURETTOR.

gauze filter *R* into the constant level tank *F*. From this tank the petrol passes along the passage *D*, and up the dome-piece *E*. Warm air is drawn in through the pipe *I*, and is intimately mixed with the petrol as the latter is sprayed against the inverted *H*. Before entering the outlet pipe *J* the carburetted air passes through two adjustable valves, one of which controls the quality and the other the quantity of carburetted air allowed to pass to the motor. Another new feature is an automatic circuit breaker, which acts in such a manner that the operation of putting on the brake first of all breaks the electrical circuit with the ignition device. The object of this provision is to make the use of the brake more effective and at the same time to reduce the wear on the same by

FIG. 3.—THE ROCHET REAR AXLE.

causing the motor to be inoperative ere it is applied. Fig. 3 gives a sectional view of the rear axle showing the differential gear, the driving pinion *A*, the band brake *B*, and the free chain wheel, *C*. These four parts are all enclosed in an aluminium gear case. This case is made in two parts and is fitted with an internal disc or partition *g*, which divides it into two compartments and thus prevents the grease in *A* from coming in contact with the brake *B*. The precise construction of this portion of the driving axle is clearly shown in Fig. 3, from which it will be noticed that the ball bearings *d* are provided with special lubrication tubes. It is stated that these machines will run 1,000 kilometres without requiring any further lubrication in the gear case.

The Benz Four-seated "Tonneau."

THE BENZ "TONNEAU."

HEREWITH we give an illustration of a four-seated "Tonneau," a type of motor-carriage body which is just now very popular in France, the latest production of Messrs. Benz and Company, of Mannheim. The vehicle has seating accommodation for four persons; it is fitted with a horizontal two-cylinder engine of 9 h.p. The crank shaft works in an oil-containing case, while a central lubricator supplies the oil for the working parts. The ignition is electrical, and the cylinders are water-jacketed, the water tank being located in the fore part of the frame. Four speeds forward and reverse motion are provided, the car being, it is claimed, able to maintain an average speed of twenty-one to twenty-five miles per hour. Steering is controlled by a horizontal hand-wheel.

MOTOR-CARS and the French military manoeuvres formed the subject of a page of interesting pictures in the *King* last week. The snapshots included the special carriage for the German attachés and that used for the transport of army officers, as well as for the commissariat department.

THE Manchester Wedge Tyre Company, Limited, is the name of a company which has been registered with a capital of £10,000 to acquire from J. Shepherd and G. Walthew certain patents granted to the said J. Shepherd in relation to improvements in wheel rims and elastic tires, and to carry on the business of manufacturers of and dealers in wheel rims, elastic tires, etc., for wheels used for road locomotion. The registered office is at Soho Works, Pollard Street, Manchester.

MOTOR-CAR owners using petroleum spirit will appreciate a new form of can for storing purposes which is possessed of two valuable features. In outward appearance the can resembles those generally used, but inside there is a pipe which extends from the outlet to the bottom and is pierced with holes throughout its entire length. Round this pipe is a gauze covering, which acts like the covering of the Davy miner's lamp in preventing flame coming in contact with the spirit. A new form of plug or cork is used, which has a brass cap held in position by a fusible solder which will melt in case of an outbreak of fire, and so allow any gas generated in the can to be liberated and prevent explosion. The can is made by Messrs. Henze and Co., of Salzkotten, Westphalia.

A DOCTOR'S EXPERIENCE WITH A STEAM CAR.

DR. A. FRANCIS STORZ, of Natick, Mass., U.S.A., who has used a Locomobile steam car for about eleven months, thus describes his experience with the same in one of our American contemporaries.

The car was one of the first turned out, but has nevertheless done very excellent service. I have covered altogether over 16,000 miles, and the carriage is as good as new. Slight repairs are, of course, necessary from time to time, but my total expense to date has been but £10. Even the tires, which are small two-inch pneumatics, are still in good condition and have yet a long life before them. The car was used throughout the winter in all kinds of weather, and in my professional business I had no trouble in operating the carriage over snow and mud, and, by winding the pipes properly, have no difficulty with freezing. Since I have received the car I have travelled throughout all the mountainous and sandy roads in Massachusetts, Connecticut, and Rhode Island. My last trip was from Boston to New York, by way of Springfield, Hartford, and Bridgeport, and returning by way of New London and Providence. Though the roads were sandy, it was accomplished without a mishap of any kind. The difficulty in most cases with steam carriages is due to the carelessness of those who have been running them, and not to the fault of the carriage. I do not pretend to be an expert operator, nor do I think I have run the machine in any unusual manner, but I think that, with regular inspection and careful operation, the steam carriage would give the best results for a physician's use, particularly in localities where roads are bad and hilly.

THE *Caterer* considers that the wealthy automobilist is likely to become one of the best paying patrons of the hotel-keeper, a fact that we have insisted upon ever since the members of the Automobile Club went a-touring.

MESSRS. W. W. BANNISTER AND Co., of Crawley, Sussex, inform us that they have now moved into larger and more convenient premises on the south side of the railway crossing and on the opposite side of the road from their old depot. Messrs. Bannister are district agents for Carless, Capel and Leonard's petrol, which may be had at any time. They also carry a stock of motor accessories and oil, and can undertake repairs of any kind to motor-vehicles.

A NOVEL AUSTRIAN MOTOR.

REFERENCE has already been made in these pages to the voiturette built by Herr Josef Kainz, of Vienna. The power of the motor is transmitted by cog wheels to the rear axle. The change of speed gearing and reverse are secured

FIG. 1. -- GENERAL VIEW OF KAINZ MOTOR.

with only one friction clutch working on the engine shaft, so that when running idle the engine is perfectly free. The leading feature of the car is the motor, which, as will be seen, is of the single vertical cylinder type; it has electrical ignition, and at a speed of 800 revolutions per minute can develop $4\frac{1}{2}$ h.p., the bore of the

FIG. 2. -- TOP VIEW OF KAINZ MOTOR.

cylinder being 96 mm., and the stroke 96 mm. It is in the means adopted for the cooling of the cylinder that the novelty of the engine lies. As will be seen from the illustrations, for which we are indebted to *La France Automobile*, the cylinder walls

are surrounded by rotating fans, which are driven by a band off the motor shaft. The lower fan draws in cool air and forces it around the cylinder, the upper fan dispersing the heated air at the top. It will be noticed that the faster the engine runs the greater is the cooling effect. The fan is made of aluminium, and runs on ball bearings. It is said to have proved itself very efficient in practice, dispensing entirely with the necessity for a water-jacket with the attendant tanks and radiating coils.

IGNITION AND IGNITION TROUBLES.*

THE electric ignition devices in actual use on the engines of motor-vehicles may be divided into two classes—viz., those in which the make and break of an electric circuit takes place inside the cylinder, and which gives the so-called contact spark; and those in which the make and break of an electric circuit occurs outside the cylinder, and which gives a jump spark inside the cylinder. The former class may again be divided into two sub-classes—igniters in which there is an end contact between electrodes, and igniters in which there is a wipe or scrape contact between electrodes.

The simplest form of end contact igniter, and one which was formerly much used with stationary engines, is shown in Fig. 1. A plug screwing into the cylinder head has an insulated bushing, through which passes one of the electrodes. This electrode has a collar, and it is held by a spring against the end of the bushing. The other electrode is a stud screwed into the piston. The two

FIG. 1.

electrodes are in line. Every time the piston comes back the electrodes touch and there would therefore be a spark at every revolution, were it not for a contact maker or switch operated from the crank shaft, which closes at the proper time every second revolution. This form of igniter is ill adapted to small high-speed engines, for the reason that the spark passes always a little after dead centre, whereas an ignition a little before dead centre gives the greatest power. On the other hand, the electrodes are in contact only for a very short time, which prevents the current from attaining its full value and reduces the volume of the spark and the certainty of ignition.

* By P. M. HOLT in *The Horseless Age*.

A modification of this igniter is shown in Fig. 2. Here a double-armed lever is interposed between an insulated electrode in the cylinder head and a stud screwed into the piston. Normally the lever is held against the insulated electrode by a spring outside the cylinder, but on the back stroke of the piston the stud in the piston strikes the lever, and brings it out of contact with the insulated electrode in the cylinder head. The spark occurs therefore always a little ahead of the dead centre position of the crank. The time of ignition can, to a certain extent, be regulated by advancing or withdrawing the electrode passing through the insulated bushing. In this type of igniter the

FIG. 2.

difficulties of the type illustrated in Fig. 1 are overcome. It is, however, not very desirable to have the first ignition occur before the dead centre, as the engine is then liable to start backwards.

Any igniter which is actuated by the piston must operate either before or after dead centre, as at the dead centre the piston is not moving. To overcome this difficulty end-on-contact igniters are now often actuated from mechanism outside the cylinder geared to the crank shaft. Fig. 3 shows one form of igniter in which the electrodes are thus operated. The two electrodes inside the cylinder are held apart by a spring outside the cylinder. One of the electrodes is free to move around a shaft passing through the cylinder or valve chamber wall. On this shaft outside the cylinder there is a pawl which engages with another pawl on the igniter actuating rod. When this rod moves

FIG. 3.

back the pawls engage and the electrodes come in contact. When the pawls disengage or snap the spring on the electrode shaft causes the breaking of the contact, and the return of the movable electrode to its original position. With this form of igniter, ignition can be made to occur at any point of the stroke. The electrodes also remain in contact for a sufficient length of time to assure a full strength of current before the circuit is opened. The igniter actuating rod is operated from a secondary shaft, geared to the crank shaft in the ratio of two to one. It may be operated either by a crank, an eccentric, or a cam. In the latter case the return of the rod has to be effected by a spring. This form of igniter in its various modified forms is used on a number of marine and motor-vehicle engines.

The wipe spark is always more reliable than the end-on spark, but there are certain difficulties in constructing these wipe spark igniters, and they are comparatively little used. It may here be stated that a wipe spark is often claimed when an end contact spark is being had. The wipe spark requires a spring inside the combustion chamber, and it is often thought that steel will not retain its temper when exposed to the heat of the explosion in the cylinder. Fig. 4 shows a wipe spark igniter which with various modifications is used on a number of stationary engines and also on one vehicle engine of which the writer knows.

As here shown, a blade of spring steel is riveted into a rod and forms one of the electrodes—the insulated one. The pin of a little crank wipes this blade during a part of the revolution of the crank. The blade is deflected by the pin, and when the deflection has about reached its maximum the pin comes to the end of the blade, the blade snaps off from the pin and thus produces the spark. The rubbing of the pin and blade together always keeps the contact surfaces clean. The spring pressure of the blade always produces a sharp break, which is conducive to better results as regards the volume of the spark. The crank is driven through gearing from the cam shaft, and revolves once for every two revolutions of the engine crank. If the engine should start the wrong way through a premature explosion the crank pin would turn up against the blade and might break it. This danger is guarded against by driving through a ratchet. The

FIG. 4.

point of ignition of such igniters may be adjusted on both electrodes. The blades for this igniter should be made of machine steel, and when they are so located that the draft of the incoming charge fans them they will retain sufficient temper to serve the purpose. The writer has found this igniter to be very reliable and efficient, and it is also comparatively simple.

For the insulation of the parts of an igniter either mica or asbestos is used. The former has the best insulating qualities, but many makers prefer asbestos because it does not crumble like mica. The mica, however, only crumbles when used in pieces of very small width. The surface of the insulation inside the cylinder becomes covered with carbon deposit after the engine has been running a while, and the surface of the insulation on the outside is also liable to become dirty. These layers of dirt and carbon cause leakage of the electric current and reduce the volume of the spark. To reduce this leakage the length of the leakage path should be made as long as possible. To this end the diameter of the plug is made larger than the diameter of the flanges of the insulated bushing and the insulating washers of the same diameter as the plug. This is indicated in Fig. 1.

(To be continued.)

THE HÉLÈNE IRONCLAD PNEUMATIC TIRE.

WHEN rambling through the Transportation Section of the Paris Exhibition a few days ago we noticed that several of the motor-vehicles were fitted with a novel form of pneumatic tires. It is known as the Hélène, and, as will be seen from the illustration herewith, its principal feature is an endless band of rubber provided with small juxtaposed plates of iron and

secured to the envelope by vulcanisation. The tire is a double tube one, to the outer cover of which is cemented a sort of shield. This shield has a flat surface on its outside, to which is fastened a belt. To this belt are riveted the metal sections, which form the main protection of the tire. This construction is claimed to do away entirely with punctures, while at the same time the tires are said not to make any more noise than the regular pneumatic tires.

TRIUMPH CYCLE COMPANY v. THE MOTOR-CAR COMPANY.

In the list of matters for hearing on Wednesday last week before Mr. Justice Buckley, sitting as Vacation Judge in the Chancery Division, was a motion for an injunction restraining the defendants in this action from using the word "Triumph," but Mr. Henderson, for the plaintiffs, said the defendants had agreed that the injunction should go against the use of the word, and also that they would pay twenty guineas in respect of costs. By consent, an order was made to that effect.

FURIOUS DRIVING CASES.

ARTHUR HARD, proprietor of a private motor-car, was charged at Swansea, on Wednesday last week, with driving it furiously in Mount Street. The constable said the car was going at the rate of fifteen to eighteen miles an hour. The defendant's solicitor said it could not go more than ten. A fine of 20s., including costs, was imposed.

At the West Hartlepool County Police Court on Wednesday, Christopher Macadam was charged with furiously driving a motor-car on the Grantham Road on August 27th. Mr. Luck, of Darlington, appeared on behalf of defendant, and, after the hearing of evidence on both sides, the chairman of the Bench said they had been unable to agree, so they would dismiss the case.

At the Stockport County Petty Sessions, last week, William Rothwell, of Whitefield, near Bolton, was summoned for furiously driving a motor-cycle in Wilmslow Road, Cheadle, at midnight on the 3rd inst., contrary to the regulations of the Local Government Board. Defendant pleaded not guilty. P.C. Richardson stated that on the night in question he saw the defendant driving a motor-cycle on the road near the White Hart Hotel at the rate of eighteen or twenty miles an hour. A man named Fred Guff Hogg, of 30, Barr Lane, Bolton, was riding four yards behind on a free-wheel machine, which was tied to the motor. Witness called out to the defendant to stop, and he called out "Good-night," but subsequently stopped. He stated that he wanted to get home, having travelled from Bolton to the other side of Shrewsbury and back, a distance of 180 miles, in the day. Inspector Skirr gave corroborative evidence, and Superintendent Oldham said the drivers of motor-cars were apt to take advantage of the police and refuse to stop. Defendant said he was travelling at the rate of about nine miles an hour, and there was no danger. Hogg gave similar evidence, and said it would have been extremely dangerous to ride behind a motor travelling at that pace. A fine of £3 and costs was imposed.

At Llangollen on Tuesday, A. E. Crowley, Elgbaston, Birmingham, was charged with riding a motor-tricycle on the Holyhead Road at Llangollen on September 15th furiously and to the danger of life and limb. Sergeant Wyse said that defendant put on speed when passing the brewery, until he should say he was going at the rate of thirty miles an hour, and he seemed to be out of sight directly he had passed. They were relaying the main drains at Llangollen, and at the place in question, as the road was up, it would have been impossible for two vehicles to

pass each other. Had anyone come down this part of the road at the time they would have found it impossible to get out of the way of the defendant. When the motor-car had passed witness proceeded to the telegraph office and wired to Corwen, the next town along the road, giving instructions to the officer there to stop defendant. This was done, and computing the time between sending off the wire from Llangollen and when defendant arrived in Corwen he must have traversed the distance between the two places at the rate of twenty-five miles an hour. Defendant said he had ridden 6,000 miles this year, and this was the first time he had been cautioned. The motor-tricycle was under complete control, and could be pulled up within ten yards. He did not go more than at the rate of eight miles an hour through the streets, but when he had a clear road before him he saw no harm in putting on pace. It was nonsense to talk of his having ridden at the rate of thirty miles an hour, for it was impossible to do so on such a machine as he used. The magistrates said they had come to the conclusion that there might be a question whether the defendant did endanger life and limb, and if he did not do this the case must be dismissed. They were all friends of the motor-car, and thought the motor-car was bound to "come," but they counselled prudent riding, and dismissed the case. The Deputy Chief-constable asked the magistrates to state a case with a view to appealing.

At the Bedford Borough Police-court last week, Percival E. Thornley, of Cambridge, was summoned for driving a light locomotive to the common danger of passengers in St. Mary's Street, on September 3rd. Defendant pleaded not guilty, and was represented by Dr. Cooper, barrister-at-law. Francis Taylor said that on Monday he was driving down St. John Street. He was driving at six miles an hour. The motor-car, driven by defendant, came along at fourteen to fifteen miles an hour. He pulled up, but defendant did not slacken the motor, which hit his horse on the chest. Defendant refused his name and address until a policeman asked him for it. The motor was coming out of Cardington Road to go into Cauldwell Street. Witness did not hear the horn blown. Cross-examined: If successful that day he was going to sue for damage to his horse. Defendant could have pulled up, but when asked he said he had no right to do so. The mud-guard to the motor was broken, and defendant said, "If I hear any more from you about the horse, I shall have compensation for damage to my car." Arthur Rogers said that he was in Cauldwell Street when he saw the motor coming. Before coming to the corner he heard the horn. The motor was going at ten miles an hour, but he could not judge at what rate the horse was going. Cross-examined: Taylor was going at six to seven miles an hour. He did not think that if Taylor had driven on he would have avoided the car altogether. P.C. Steer, of the County Police, said that on September 3rd he was in St. Mary's, when he heard a crash. He turned round, and saw the motor go down Cauldwell Street at a great rate. Cross-examined: He saw Taylor before the collision, and he was driving at five miles an hour. He did not see the motor before he heard the crash. Dr. Cooper, for the defence, said the charge was not one of excessive speed, but was that he drove the car to the common danger of the passengers. He would also draw attention to Taylor's evidence, which was in many ways contradicted by the witness Rogers. He would call the defendant and his friend, who would prove that they were travelling with proper caution and were not going at more than six miles an hour. Defendant, on oath, said he was an undergraduate at Trinity Hall, and on the day in question he was driving the car, with a Mr. King. He had driven a car for several months, and he had also driven in London. When he approached the crossing he slackened speed to 6½ miles an hour, and sounded the horn. He saw Taylor when he was at the crossing, and was four yards away. As he was passing he put all the speed he could in order to get out of the way. Taylor also put on speed. Harry Heath King, a non-collegiate student at the University, gave similar evidence. The Bench fined the defendant 30s. and the costs, 14s.

MR. J. J. MANN can be seen at the showrooms of Messrs. Kesterton, in Long Acre, where the Marshall car is on view.

THE Mazawatee Tea Co., Limited, have, through Messrs. Julius Harvey and Company, engaged a fleet of four motor-cars to convey members of the staff and clients between their offices and dépôt in the City and the large new works just completed at New Cross. A first car—a Motor Manufacturing Company's phaeton—has just been put in service. We ourselves had occasion not long ago to visit the site of the Mazawatee factory at New Cross, and think the company have done well in establishing their own means of rapid communication with the City.

THE Liquid Air Power and Automobile Company of Great Britain, Limited, has been registered with a capital of £200,000, to adopt and carry into effect an agreement made between T. J. T. Hutson of the one part, and this company of the other part, and, generally, to carry on in all or any of their respective branches the businesses of manufacturers of and dealers in liquid air and all the apparatus and things used in connection therewith; as electrical and mechanical engineers, motor-car, cycle, and carriage makers, etc.

THE Motor-Car Journal.

VOL. II.]

LONDON, SATURDAY, OCTOBER 6, 1900.

[No. 83.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

WE have already referred to the rather general use of the automobile during the General Election, and now give two or three miscellaneous items of news which may be of interest to our readers. Mr. O. Stanton has been helping Mr. L. Harmsworth on

his motor-car in the latter's candidature for Caithness. At least one Yorkshire candidate, Mr. A. W. Black, in the Doncaster division, declared himself in favour of the taxation of motor-cars. In London constituencies the motor-car has not been so largely employed as might have been expected. Mr. Ridley drove round South-West Bethnal Green on a car on Tuesday, and in Battersea both candidates had friends who had commandeered similar vehicles. Mr. Mark Mayhew drove Mr. Burns about the constituency on his Peugeot car, which was able to overlap the coach and horse employed in the interest of the opposing candidate. In West Marylebone, Mr. Leopold de Rothschild lent a motor-car to Sir S. Scott, and Mr. H. Allhusen, the candidate for Central Hackney, rode a motor-car on Thursday. The Hon. J. Scott Montagu's motor-car did good service at Christchurch. As might have been expected, motor-vehicles were popular in Coventry on the day of the election. On the day after a driver was charged with furious driving, and when the magistrate asked the pace at which it went he was informed by the defending solicitor that it had gone for the 1,070 majority—the plurality obtained by the candidate in whose interest it was engaged. The General Election has had the effect of confirming many public men as to the reliability and utility of motor-vehicles for both private and public service.

The Second Ascent of Porlock Hill.

WITH regard to the ascent of Porlock Hill by a Benz car, to which we referred a fortnight ago, and which has occasioned much comment, we are glad to be able to publish an authoritative statement from Mr. H. N. Hickley, of Taunton, who was the owner of the car in question. Writing on the 27th ult., he informed us as follows:—On Monday week last, leaving Castle Cary about 10 a.m., I drove through Ilminster, stopping there about an hour, and coming on to Taunton, calling at the Newton Electrical Works, of which I am manager. There I filled up with petrol, etc., and started for Porlock at about 4 p.m. I believe I am right in saying that, out of the many attempts which have been made, one car only had previously got up this hill, and it with a certain amount of preparation. I made no preparation whatever, not even stopping in Porlock, and reached the top of the hill at about five miles an hour, stopping once in the ascent. I met the Lynton Coach, due in Porlock at seven, at the summit. I returned to Taunton the same night. There were two of us in the car, which was fitted with a Benz twin-cylinder motor of 5 h.p. and weighed 11 cwt.

Horse v. Motor-Car up Porlock.

INTEREST in Porlock Hill is likely to be quickened by a forthcoming event, full particulars of which we hope to publish when the definite arrangements are made. During the next few weeks, probably on the first Saturday in November, there will be a race between a motor-car and a horse. Mr. Mark Mayhew will be the champion of the automobilists, and will most likely drive his 16 h.p. Napier car, which is just about ready. Captain Harvey Jay, the well-known racing man, will ride a horse up the hill. The car will start up Porlock Hill five minutes after the horse, and both contestants will be timed with chronometers at each end. The event should prove of great interest to sportsmen of every description, and the victory of the horse will probably be assumed by a great many people.

Tintern Abbey.

ELSEWHERE we give some particulars of the autumn tour of the Automobile Club, with the names of suppliers of petroleum spirit by the way—names that will be useful for reference by all motorists. The visit to Tintern Abbey comes almost immediately after the welcome assurance that it has been purchased by the Government. Nor is it the abbey only, unrivalled as it is even among the ecclesiastical ruins of England, that changes hands. The estate of 5,334 acres of land has been acquired, including nearly 3,000 acres of woodland, the most picturesque portions of which are the lofty wooded hills and slopes with a frontage of not less than eight miles to the River Wye. The famous Moss Cottage and Wyndeliff, from which seventeen counties are said to be visible, form part of the purchase. The estate is near the extensive woods of the Crown in the Forest of Dean, to which it will form a most valuable addition. At the same time, the Crown has also purchased the whole of the Duke of Beaufort's farms surrounding Raglan Castle, 3,169 acres in extent. These will be seen by the automobilists after the luncheon at Lord Llangattock's house.

Motor-Bicycling over the Alps.

THE enjoyments of his motor-bicycle trip from Paris to London via the Alps are being described by Mr. Joseph Pennell in the *Daily Chronicle*. The first article appeared on Saturday and should do something to dispel the idea that it is not possible to purchase a motor-bicycle which is a practical vehicle. Incidentally the writer remarked that every French town now boasts its repairer of automobiles "as every English town seems to glory in his absence"—a reproach now being rapidly removed; and although at Salins, Mr. Pennell ascertained the recognised repairer was away, he had help from the local coal merchant, the chemist, the wine grower, and the hotel proprietor, all of whom owned motor-cars. Having crossed the frontier into Switzerland he ran out of petrol at Sion, and the chemist's jar of benzine proved an excellent substitute. All the hills were climbed successfully, and the rider seems to have had a splendid time.

The Exercise of Motor-Bicycling.

REPLYING to those who say that the motor-bicycle allows no opportunity for exercise, Mr. Pennell writes in a strain which will probably cause some discussion. Hence we give his views, and his criticisms of other automobiles, in full. "The motor-car," he says, "is either the advertising medium of the manufacturer and the racing man, or the latest mark of pecuniary superiority that the rich can exhibit. The quadricycle and most tricycles I have seen are the snare by which the would-be motorist is trapped. They possess all the disadvantages of the car, and many more of their own. The trouble with all these forms of motor is that, if anything breaks, owing to their weight, they must be either repaired on the spot or dragged away by horses. On the other hand, the motor-bicycle—and I speak of the Werner, which I alone have really driven straight away for about a thousand miles—is a heavy safety bicycle, with a strengthened frame, over the front wheel of which an auxiliary motor is placed. This motor, of one horse power, is capable of various speeds, from three miles an hour up to about thirty-five, and the driving of it requires the same, or, rather, a great deal more care and attention than the driving of an ordinary safety bicycle. As a matter of fact, however, by pedalling up hill, and there is no real work in it, you can assist the motor, actually doubling its speed. Recently, in riding from Newhaven to Brighton over the very hilly coast road, I pedalled almost the whole way, just for exercise, and I was fifteen minutes going from one town to the other. On the level, too, you help the motor, and a considerable amount of pedalling is done in a day's ride. So, if exercise consists in working your legs, on a motor-bicycle you get a good deal of it. But the advantage of this machine over all others is that, in case of the breakdown of the motor from any cause, the driving belt can be disconnected, and the machine ridden as an ordinary safety, which is very little more difficult than riding an ordinary tricycle."

The Forthcoming Trials of Electrical Vehicles.

ARRANGEMENTS are well in hand for the trials of electrical vehicles which the Automobile Club is organising for the first week in November. The trials will comprise:—(i.) A run over a given course for an unlimited distance on one charge. The driver to declare to the observer when the run is to be considered as finished; (ii.) A course of thirty miles to include considerable gradients; (iii.) A course of thirty miles of average road; (iv.) A course of thirty miles of flat or nearly flat road. The cars will remain throughout the trials under the supervision of the Club judges, and the energy consumed, number of passengers carried, average speed, etc., will be recorded on the certificates. The Judges' Committee will meet shortly to determine the courses and to consider a suggestion that the Trials should be extended to include prolonged battery-tests.

A Run on a Locomobile Steam Car.

ONE of the latest additions to the ranks of automobilists is Mr. S. Dakeley, of Blaenau Festiniog, whose choice of vehicle has fallen on a Locomobile steam car. Mr. Dakeley took delivery of his car in London lately, and on the 21st ult. set out for home, accompanied by an instructor. Mr. Dakeley describes the run as a most enjoyable one, the 350 miles being done comfortably in three days. On one of the days over 135 miles were covered, notwithstanding that in places the roads were in a very bad condition. The last twenty-five miles of the journey lay right over the Welsh mountains, but the little steam-car took the hills with ease.

Another Steam-Car Enthusiast.

ANOTHER owner of a steam carriage, who has driven his vehicle but a few weeks, but who has in that period, he declares, experienced all the disadvantages, speaks very strongly in favour of that type of carriage. He says: "For touring and pleasure vehicles, unrestricted to town use, the steam carriage is

the best of any. It is not only the lightest and most comfortable, but goes along with the least fuss and noise. Little energy is wasted and the control of the machine is marvellous. The speed is so easily regulated that a half mile an hour can be added or deducted by the use of the lever. The speed of which they are capable is almost unlimited. I know that my machine will go much faster than I dare to run it, and this reserve force gives it hill-climbing powers that neither the petrol nor electric carriages possess. I don't believe in looking for perfection in everything, and there are disadvantages connected with the steam carriage. In the first place the machine is a little too complicated and delicate. In reducing the weight I think some of the strength and ruggedness has been sacrificed. There are too many gauges and delicate bits of machinery to get out of order. I am forever smashing the water glasses on my machine. They are a nuisance, and I hope to see them superseded by a bell or whistle to inform the *chauffeur* when the water needs replenishing."

Police and Automobiles.

ITALY is making progress—automobilistically, if the printers' reader will allow such a lengthened word. Not only have motor-cars been successfully introduced into the post-office and the army, but the police of Rome are about to experiment with automobiles. Seeing the acknowledged utility of the patrol and the policeman on bicycles, there is every reason to hope the automobile can be employed in the detection of crime with even more satisfactory results. Not only will such an innovation secure greater facility in covering the wide area which the rural police have to patrol, but it will also prove useful in many smaller matters.

A Capture by Motor-Car.

IN confirmation of the foregoing a Dalziel's telegram from Paris on Wednesday evening is interesting. The capture of a welsher at Bernon by means of a motor-car is reported. Two Americans, having won, proceeded to look for the bookmaker who had the wagers with them. He was not to be found on the course, but the Americans learned that he had left in time to catch the next train to Paris. There was only eight minutes before the train was due to start, and the Americans, securing the assistance of a police officer, mounted a motor-car, and drove full speed to the station. The car attained a speed of fifty kilometres an hour, and raced so furiously through the village that the police officer had to hold on with both hands, and could not return the salute of his inferior officer passed *en route*. The car reached the station two minutes before the train, and secured the welsher. The next day he was sentenced to a fortnight's imprisonment, and the police officer is proceeding against the Americans on a charge of furiously driving their vehicle.

Motor Dust-Carts for the City of London.

WE notice that the Streets Committee of the Corporation of London are again taking action with regard to using motor-vehicles for the removal of dust and trade refuse, etc., from the City to the Corporation Depot at Letts's Wharf, Lambeth, S.E. On the present occasion the committee only proposes to hire a "mechanically-driven" dust-cart, and they announce that they are prepared to consider proposals from firms or persons experienced in the manufacture and use of automobiles. It is very surprising that the City authorities should have bungled so completely in the matter in the first instance. Why did they not make inquiries of some of the other local authorities, and thus have saved themselves the trouble of advertising for an electric dust-cart? In our advertising pages this week will be found an announcement on the subject, and we hope that now, at the third time of asking, success will attend their efforts. Manufacturing firms and others should render every assistance,

Excessive Speeds.

THE outbreak of the racing fever, which has followed the return of some wealthy Americans from foreign shores, seems to be leading to dangerous excesses in the United States. One of these multi-millionaires has been amusing himself by mounting his German racing machine and smashing records over the roads from Newport to Boston to the consternation of the citizens and the discomfiture of the authorities *en route*. Time and again the young Croesus has been brought before the magistrates and fined for reckless driving; but what does a multi-millionaire care for a police-court fine? He is perfectly willing to pay one every day for the privilege of indulging in this sport, which for the nonce pleases his fancy. But what, asks the *Horseless Age*, of the automobile industry, which must bear the stigma of his bad example and be still further restrained of its rights upon the road? Fortunately the number of mad motorists in this country is ridiculously small, but in America it is growing to such an extent that imprisonment will have to be threatened to make the punishment fit the crime.

Automobilmism in Holland.

ALTHOUGH not so much is heard of automobilism in Holland as in France, Germany, and several other countries, yet the movement is slowly but surely progressing in the country. At the recent general meeting of the Automobile Club of Holland it was announced that the membership list showed a total of seventy-five names. The club has succeeded in establishing sixty-one depôts for the sale of petroleum-spirit in various parts of Holland, and has made special arrangements with a number of hotels.

The Wellington Voiturette.

WHEN visiting Mr. Frank J. Wellington's depôt at Chalk Farm, a few weeks ago, we were shown a new motor-voiturette in course of construction. As the work was then only in an elementary stage, we made no mention of the matter, but we are now able to give a few particulars of the car, the body of which takes the form of a three-seated spider. Recognising the fact that many of the light cars on the market are under-powered, Mr. Wellington is employing a 5 h.p. Aster water-cooled engine. The feature of the new car is, however, the patent silent variable-speed gear that is adopted, which, it is claimed, will give any speed from 4 up to 30 miles per hour, and also a reverse motion. Mr. Wellington has been a long while testing this special gear, and finds he will save a good deal of power, there being so few bearings. We are promised drawings and full particulars of the vehicle, as also a trial run on it at an early date.

Repairing Firms.

THE subject of repairs to motor-vehicles is a very important one, and not only are the leading motor-car firms appointing repairers to attend to the requirements of special types of machine, but the Automobile Club is also about to consider the subject. Already a list of repairing firms is in circulation among members of the Club, and criticisms as to the ability of those on the list are being invited so that only really competent persons shall be officially recognised. Those repairing firms who have not yet applied to be placed on the list should do so without delay, and also forward to the Club certificates from members concerning their capabilities.

The Need of Education.

AN accident has occurred in Manningham Lane, Bradford, in which a motor-car, a butcher's cart, and a Parliamentary candidate's carriage were involved. The motor-car belonged to the Yorkshire Motor Vehicle Company, and collided with the butcher's cart sustaining some damage. The horse bolted and galloped away at a furious rate, dashing against a

horse and trap belonging to Mr. W. E. B. Priestley. The coachman was precipitated to the road, and sustained two scalp wounds, which were attended to by Dr. Waddington. Why cannot owners of horses secure them a proper and complete education with a view to avoiding such exploits as those detailed in the foregoing lines? Had that horse been carefully educated and taught to behave with propriety nothing of the kind would have happened.

Petrol on Sunday.

THERE is often great difficulty experienced in obtaining supplies of petroleum spirit on Sunday, and motorists who have neglected to replenish their stock on the preceding day have frequently been stranded. Hence we are glad to hear of the arrangement made by Mr. F. S. Frampton, of Winchester, which will meet the wants of motorists who are likely to go through that city on the Sabbath. He has arranged with the proprietors of the Market Hotel and Royal Hotel that each will keep a two-gallon can of petrol for emergencies, and will also receive any quantity that may be ordered from Mr. Frampton in advance on Saturday before sunset. Thus a difficulty is bridged in a way that should commend itself to other dealers in petrol who have scruples with regard to Sunday trading.

THE VALLEE "SHOE" CAR TRAVELLING AT FULL SPEED.

American, of course.

THE fact that automobiles do not defile the streets is a strong argument in favour of their extended adoption. Municipal authorities would quickly realise their advantages in a reduction of the cost of street cleaning. Emphasising this point, we notice that a Chicago newspaper suggests that the time may come, in a not distant future, when cities may require a licence for the privilege of using a horse in the streets, so as to require owners of horses to pay the expense which their use imposes on the public. For the horse is not only dirtier in the streets than the automobile, but he is also more destructive of the roads.

Motor-'Buses.

THE vestrymen of Lambeth, anxious to secure rest and quietude for the residents of that sylvan locality, have decided to call the attention of the Chief Commissioner of Police to the noise made by the motor-'buses which run that way. There was a little discussion on the matter, and, despite the fact that one observant gentleman pointed out that some motor-vehicles were worse than others, it was decided to appeal to Scotland Yard. We believe there are one or two noisy motor-'buses in London, but they must not be made the reason for an attack on new systems. Lambeth vestrymen should remember that this method of locomotion has not reached its best developments, and should try and compare the noise of motor-cars to-day with that they made two or three years ago. They are becoming less irritating to the dweller in quiet streets.

Cost of Horses.

IN the South African War rather more than 200,000 horses have been employed. At least, that is the number of horses and mules exported from various foreign countries to the order of the British Government for transport use and for remounts in connection with the Transvaal. According to one authority, had such an order been placed solely in the hands of the British farmer the average price would have risen to not less than £150, or an outlay of £30,000,000. As it is, the 45,000 horses and mules purchased by our agents in New Orleans average only £21, while the Continental nags cost £80 apiece. Seeing that an automobile could be found to take the place of several horses in the work for which they were required in South Africa, is it not time more was heard with regard to the intention of the War Office in the matter of automobiles for military purposes? In addition to the *King* we are glad to notice in this connection that the *Graphic* and the *Black and White Budget* have been illustrating the automobiles employed in the French manoeuvres.

**Dismissal
of a
Motor-Car Case.**

WE congratulate Mr. Frank H. Butler, the hon. treasurer of the Automobile Club, and his solicitor, Mr. Bannon, on the dismissal of a charge of furious driving alleged against him at New Romney. At the local police-court Mr. Butler was charged with driving his Panhard car at the rate of eighteen miles an hour. He appeared personally to rebut the evidence of two constables in plain clothes, and the magistrates then dismissed the case. This is noteworthy and demonstrates the advisability of defendants in such cases appearing to give evidence. For the magistrates naturally are inclined to give greater credence to the sworn evidence of riders and drivers than to the speeches of solicitors only.

**Enterprising
Journalism.**

ONE of our most interesting automobile contemporaries is the *Automobile Magazine* of New York. Its September number was exceptionally good. There were several splendid articles and some effective illustrations, among the best being several taken from our columns without the acknowledgment that courteous journals generally give. From our issue of February 23rd, a description of the Canello-Durkopp motor-carriage, with four illustrations, an article on new English voitures, with two illustrations, another on an English motor-omnibus, with a special photograph, and also one on a French motor omnibus have been taken without any recognition of their origin. In order that its readers should also have less modern news, our contemporary has reproduced in the same issue for September an article on the Hugot motor-voiturette which appeared in our columns in October of last year. It is some tribute to the interest and value of our technical articles that they should thus obtain wide publicity across the Atlantic. Of the apparently original contributions to the *Automobile Magazine*, a seven-line article on automobiles used for towing is perhaps the most notable.

ONE of the latest converts to automobilism is Count Hermann Hazfeldt, son of the German Ambassador to the Court of St. James.

THE MASSACHUSETTS ELECTRIC CAB CO. has placed two electric cabs in service and established a regular stand in Court-square, Boston, U.S.A.

MESSRS. TURCAT and MERY, of Marseilles, have just commenced the manufacture of motor-cars on Mors-Panhard lines. The motor will have four cylinders, which will be carried in front of the car, and will develop fourteen horse-power at a speed of 800 revolutions per minute. Magneto-electric ignition on the Bosch principle is to be adopted, as also water cooling by means of radiators fore and aft with fans on the Cannstatt Daimler principle. Five speeds forward and reverse motion will be available.

PARIS EXHIBITION NOTES.

(FROM OUR OWN CORRESPONDENT.)

(Continued from page 503.)

DIRECTLY facing the De Dion and Bouton exhibit at Vincennes, but upon the other side of the road, is found the main building of the automobile section, the interior of which presents a truly desolate and unkempt appearance. The majority of vehicles shown are occasionally utilised for trial trips, etc., and as they are invariably driven direct from the road to the stand they are usually to be seen in a thoroughly dirty condition. Most of the exhibiting firms have long ago ceased to retain a representative, so there is now an absolute dearth of attendants, and the visitor must obtain as best he can any information he desires. This is not rendered any easier by the fact that with the attendants all printed matter has disappeared, and catalogues are now seldom if ever seen. All this, to the man who takes a genuine interest in the automobile, whether from a sporting or industrial point of view, is very annoying, and he is to be excused if he says things about the exhibition, the exhibitors, and all connected with them.

The first stand that one sees upon entering is that of M. Jeantaud, who exhibits one of his well-known cabs and a couple of Panhard cars. Both these latter carry 8 h.p. motors; but, whereas the one car is of the dog-cart type, the other is a large six-seated carriage, fitted with a canopy. M. Georges Richard exhibits but a single car, and this is also the extent of the display made by M. Ripert, of Marseilles. Both these types of vehicles employ a combination of belts and cog-wheels for the purpose of transmission. La Compagnie Générale des Cycles show one of their Rochet quadricycles, fitted with an Aster motor and the wonderful Rochet carburettor. M. Fernandez exhibits one of his Sirène 3½ h.p. voitures, some of which have already been seen in England. The Créanche Company have upon their stand a voiturette fitted with a 3½ h.p. water-cooled De Dion engine, and a quadricycle also carrying a De Dion motor. There is also to be found on their stand a neat little electric voiturette, of which the motor and accumulators bear the well-known mark B.G.S. MM. Mildé and Cie exhibit an extraordinary-looking electric car, provided with three wheels. The motor is attached to the rear of the frame, between the two back wheels, and the vehicle is built very low indeed. The battery of accumulators consists of forty elements, and has a capacity of 65 ampère-hours, its total weight being about 220 kilos. Some 85 kilometres, or 53 miles, can be covered on one charge. The car weighs 520 kilogrammes and measures 2m. 50 in length by 1m. 30 in breadth. Other electrical companies exhibiting in the vicinity of MM. Mildé and Co.'s stand are the Compagnie Internationale de Transports Automobiles (Jenatzy) and the Compagnie des Voitures Electriques (Krieger). The former society shows a large delivery van, but M. Krieger's exhibit consists only of a *coupé* body.

MM. Emile Ouzou and Cie exhibit a tricycle and a quadricycle both fitted with "Soncin" motors. They have also upon their stand a pretty, albeit rather too showy, voiturette, also carrying a "Soncin" engine. The carriage work of this little car is of polished aluminium edged in brass, and under the sun's rays it doubtless presents a dazzling appearance. The motor is attached behind, but a sloping bonnet in front gives one the impression that the motor power is generated at that end of the frame. The wheel steering is mounted upon a sloping pillar. By the side of this, and attached to it, is a second pillar carrying five small regulating levers. The general appearance of this little car is particularly smart and attractive. Place is also found upon MM. Ouzou and Co.'s stand for a 5-h.p. water-cooled Soncin motor. MM. Ed. Molas, E. Lamielle, and A. Tessier exhibit the large delivery van propelled by compressed air, recently described in the *Journal*. A feature of this vehicle is the pivoting of the fore-carriage, which permits of the accomplishment of extraordinary steering feats. Only a single specimen of the Raouval car, built by the Société Anonyme Mécanique Industrielle d'Anzin, is exhibited by the makers, but it is a really

handsome carriage. The motor is placed in front, and one notices at once the large fly-wheel and clutch which are characteristics of this type of car. The wheel steering, too, is carried on a very sharply inclined pillar. Four people, all facing forward, can be accommodated in the smart carriage body built by Felber. La Société L'Automotrice de Bergerac, whose represen-

is entirely devoid of any such combinations, rejoicing as it does in a direct drive, is that constructed by the Etablissements Hautier, of Auteuil (Seine). This vehicle is provided with a Soncin motor. A carriage which attracts considerable attention is found upon the stand of M. Amedée Bollée. This is the famous steam-car built in 1878, and known as La Mancelle. That this

doyen of cars is still in good order was amply demonstrated at one of the recent fêtes, when, under the guidance of M. Amedée Bollée père himself, it careered gaily round the Daumesnil track. As a curiosity the vehicle shown by M. Albert Deschamps, Lisieux, at once attracts attention. It is certainly labelled "voiturette de démonstration du Nouvel Avant-train moteur directeur," but why such an uncomfortable vehicle has been selected to demonstrate Mr. Gouchon's system I cannot conceive. A four-wheeled car, the seat for a couple of passengers is placed right at the rear and directly above the two back wheels. At the other extremity is a vertical two-cylinder motor, with the flywheel placed between the two cylinders. This motor is attached at its base to a metal ring, which moves easily within a second ring. From the motor shaft a leather belt drives on to a second shaft, carrying at each extremity a pinion which engages direct with the road wheels. These latter are very small, and can pass well beneath the framework of the machine. By means of a pair of bicycle-like handle-bars, they can be turned to

any angle, the motor moving with them, and the vehicle is therefore capable of steering feats quite out of the common. How either of the persons placed upon the only seat can reach the handle-bars I know not, but possibly that seat is but a dummy, and the driver is accommodated upon the footboard which runs between the front and back wheels.

FIG. 1.—GENERAL VIEW OF PENELLE CAR. (See next page.)

Cliche de]

[Le Chauffeur.

tative at Paris is M. Alleron, show a car built on Benz-like lines, but fitted with a Popp motor. The cylinder head of this horizontal motor is at the rear of the car, and below the motor shaft runs a second shaft, the drive between the two being effected by a very short length of belt. Other voiturettes are shown by M. Th. Klauss, Boulogne-sur-Seine, and M. A. Query, of Paris, but neither make presents any features of interest. A rather effective display is made by the constructors of the Stella cars, whose works are situated at Levallois-Perret (Seine). They show three voiturettes, one of which is fitted with an air-cooled Aster, another with an air-cooled De Dion, and the third with a water-cooled De Dion motor. In each case the motor is carried behind, and the speed change gear lever passes through the centre of the tubular steering pillar. The Compagnie Bardou, of Paris, exhibit a *coupé*. Driver and footman find accommodation on the front seat of this car, while a couple of passengers can be carried inside. The Bardou cars are built at Puteaux, in the works formerly occupied by the Gaillardet Company. Upon the Decauville stand one finds four voiturettes, too well known to require description. These little cars enjoy an ever-increasing popularity in French automobile circles.

MM. Panhard and Levassor's exhibit consists of five cars, but several are of types now somewhat old. A couple of the vehicles are of large dimensions — one, indeed, finding room for a dozen passengers. An old friend is recognised in the shape of a 4 h.p. dogcart, a type of carriage that one does not now often see. MM. Mors, Delahaye, De Dietrich, Gobron and Brillié, Darracq and Peugeot are all represented, but their exhibits are not numerous and present no novelties. The well-known Lyons firm, MM. Audibert and Lavirotte, have upon their stand a car and a frame, the latter giving the inquisitive an opportunity of studying the means employed to transmit the propulsive power by a combination of belts and gears. A car, or rather a voiturette, which

Cliche de]

FIG. 2.—PLAN OF PENELLE CAR. (See next page.)

[Le Chauffeur.

MM. Gardner and Serpollet, Rochet and Schneider, Turgan and Foy, and La Maison Parisienne are represented by various types of carriages, and M. Chaboche, Paris, exhibits a large "tonneau" wagonette with accommodation for six people. In this case steam is the motive power.

Those English automobilists, who have made the journey by

road from London to Paris, *en* Havre, will assuredly examine with interest the car exhibited by MM. Tourand et Cie, for probably one and all of them have met the head of the firm at Havre, and ascertained what an enthusiast he is on automobile matters. The vehicle which he shows is a *tonneau*, built to accommodate four persons. The motor is carried in front, and a single lever actuates the forward and reverse gears, and changes the speeds. It is a smart and workmanlike carriage. MM. Brouhot et Cie, Vierzon (Cher), exhibit a couple of carriages and a delivery van, of which the feature is the absence both of chains and differentials. The two voituresses shown by M. Penelle, of Melun (Seine et Marne), are both fitted with the motor known as the "Touriste," constructed on the system of Mr. J. Bouché. MM. Brissard et Fils, Paris, exhibit a tricycle fitted with a De Dion motor, but carrying a water-cooled cylinder head. In place of the ordinary long petrol tank placed beneath the cyclist's seat, there are two tanks—one containing petrol and the other water. The quantity of water carried is but small, and is passed through a cooling coil placed on the left of the motor.

Other French constructors exhibit, but there is nothing calling for special attention, and one can proceed to the foreign sections without loss of time. The first is Italy, but beyond a pretty little pavilion there is no sign of Italy's existence. As for America—well, a couple of Riker cars, four Stanleys, and two carriages from the American Electric Vehicle Company, of New York, make up the sum-total of exhibits emanating from the other side of the water. Not famous, you say, but what about England's share in the show? As far as carriages are concerned, just on all fours with Italy's display, that is to say, nothing at all. The sole representative of the English industry is the Mossberg Roller Bearings Company, and the wide extent of blank space testifies as to the amount of interest taken by English automobile constructors in the Paris Exhibition of 1900. Germany, on the other hand, is fairly well represented, and the section is handsomely installed. Daimler does not show unfortunately, but both Dietrich, of Niederbronn (Alsace), and Benz, of Mannheim, make capital exhibitions, and much interest is taken in the first petrol motor-tricycle constructed by the latter firm, and which occupies a prominent position upon their stand. A magnificent electric vehicle is shown by Kühlstein, of Berlin, a sort of combination of coach and omnibus. This firm also exhibits a gear-driven two-seated car carrying a petrol motor in front. An electric tramcar, carrying its passengers on two long back-to-back seats, is shown by Die Gesellschaft für Verkehrs-Unternehmungen, of Berlin, and by way of contrast there are placed immediately in front of it a couple of motor-bicycles made by the Ateliers Ducommun, of Mulhouse (Alsace). Upon these machines the motor is carried above the front wheel, but by means of a long belt the drive is made on to the back wheel. The Vulkan Automobil Gesellschaft, Berlin, exhibit a couple of electric dog-carts, and a motor-lorry is shown by the Luxsche Industriewerke Gesellschaft, Ludwigshafen on Rhine. Other exhibitors are the Motorfahrzeug Gesellschaft, Berlin; Heinrich Scheele, Cologne; Frederick Hering, Gera-Reuss. The last-named exhibits an interesting collection of wheels. I hope to give some supplementary notes relative to this section at an early date, for it is the only one in the Vincennes annex which in any degree presents an appearance worthy of the Paris Exhibition for 1900.

(To be continued.)

MR. C. J. FIELD, of the De Dion-Bouton Motor Company, of Brooklyn, accompanied by Mr. Andrew Binker and Mr. F. H. Ball, recently took a trip down Long Island on a De Dion voituress. A considerable portion of the roads was found to be very dusty, owing to the fact that there had been practically no rain for two months. The average time of the vehicle was over 15 miles per hour and was maintained throughout the trip, except for about 10 miles in crossing the Island from East Cove to River Head, where, owing to the deep sand, it being eight and ten inches deep, much slower time was made over these 8 miles. The total distance of the route travelled was about 120 miles.

THE PENELLE MOTOR-CAR.

THE illustrations, Figs. 1 and 2, on page 519, show respectively a general view and a plan of the light car which has lately been put on the market by M. Penelle, of Melun (Seine-et-Marne), France. The frame is built up of channel steel and wood, and carries the motor and the whole of the transmission gear, thus forming a standard under-carriage to which any type of body may be fitted, Fig. 1 showing a three-seated spider. As will be seen from the plan, the engine is located centrally in the rear of the frame; it is of the two-cylinder horizontal petroleum-spirit type, and is known as "Le Touriste." The cylinders are 105 mm. diameter and 160 mm. stroke, and running at a speed of 600 revolutions per minute the engine is said to develop 6 h.p. The ignition is electrical, while the cylinders are water-jacketed, the circulation of the water being maintained by a pump. A radiating coil is fitted in the fore part of the frame in connection with the water circulation. Ample lubrication arrangements are provided for, and the sparking plugs can be quickly removed, they being mounted on a single detachable plate.

Three speeds forward and one reverse are available, the car being capable, it is claimed, of maintaining an average speed of 30 kilometres (nineteen miles) per hour. From the motor-shaft the power is transmitted by a single belt to a short countershaft. No fast or loose pulleys or friction clutch are employed, but instead a jockey pulley is provided by means of which the belt can be tightened or slackened as desired. The countershaft carries, in an oil-containing case, a train of spur-wheels, any one of which can be made to mesh with corresponding pinions on the differential shaft, from which the power is transmitted to the rear axle by the usual duplicate set of sprocket-wheels and chains. Steering is controlled by a wheel mounted on an inclined or vertical column as desired. A foot pedal operates a hand brake on the differential shaft, while a hand lever operates the jockey pulley on the belt, and at the same time applies band brakes on the hubs of each of the rear wheels.

A 6 H.P. STOEWER petrol car set out from Stettin on the 17th ult. bound for Paris, the passengers being Messrs. Stoewer, Dobberwitz, and Zimmermann.

M. ORLOVSKY arrived in Paris on Monday, having ridden on his motor-tricycle from St. Petersburg. With no intention of record-making, the ardent motorist covered about 1,800 miles within a fortnight.

THE exhibition of motor-cars at Sheffield in connection with the 1,000-mile Trial gave a decided fillip to motoring in the district, the number of motorists having more than trebled since the event.

It is not difficult to imagine that the commercial traveller will ere long be travelling by motor-car, making the trip not by railway schedule, but at his own convenience. Road maps, distances and conditions of roads will then be studied in the place of railway time-table, and the subject of roads will take the place of politics and the weather for general conversation.

WRITING to an American contemporary, Mr. L. D. Shaw, of Everett, Mass., U.S.A., states that in the year of 1866, when the old velocipede fever was on in Boston, he built a successful steam road carriage, of which the following is a brief description: It had a pair of reciprocating reversible engines, with 3 x 6 in. cylinders. The engines were secured in a horizontal position upon the frame or perch of the carriage, acting upon the crank shaft, which had a pinion gear, geared into a large spur gear, secured to the hubs of the rear wheels. The boiler was built on the plan of an Amoskeag fire engine boiler. It was 18 in. in diameter and 30 in. high, and rested upon springs on the frame back of the carriage body. Under the seat was a water tank holding 15 gals. of water, with a fuel box. The steering was done by turning the forward axle and wheels. A rack was attached to the axle, running through a rack box gearing into a small pinion, upon the end of a shaft extending up in front of the seat with a crank upon the top to operate the same.

TO MONMOUTH AND BACK.

GREAT interest is being taken in the Autumn Tour of the Automobile Club, which commences on Friday, the 5th inst. A large number of members have intimated their intention of participating in the event, and a start will be made from Horse Guards Avenue at 2.30 p.m. The route for the first day will be *via* Pall Mall, St. James's Street, Piccadilly, to Hyde Park Corner, through Hyde Park (except cycles), *via* Barracks and Albert Memorial, Kensington, Hammersmith Broadway, Turnham Green, Gunnersbury, Kew Bridge, Brentford, Hounslow, Colnbrook, Slough, and Maidenhead, Henley, Nettlebed to Wallingford, where a stay will be made for the night, the George Hotel and the Town Arms Hotel providing the necessary accommodation. This will be a forty-eight miles run, and among the petroleum spirit-stores on the way are the following:—

Brentford—Box and Co., High Street. Slough—J. Fulbrook and Co.; F. Parker. Maidenhead—Thompson and Walton; E. C. Smith. Henley—Hickman and Son. Wallingford—The George Hotel.

On Saturday the tour will be resumed at 10 a.m., and the road will be taken *via* Harwell to Wantage, a distance of fourteen miles. Then through Faringdon, Lechlade, and Fairford the party will go to lunch at the King's Head Hotel, Cirencester, 27½ miles. Leaving there the way will lie through Gloucester (17½ miles) and Ross (16½ miles) to Monmouth (10½ miles), making a total mileage of 85½ for Saturday.

Firms supplying petroleum spirit on the way are the following:—Faringdon—G. E. Liddiard, Grocer. Cirencester—J. H. Cock and Co. Gloucester—Pitt and Son, Barton Street; Clark and Morgan, 1, Worcester Street; W. J. Newth, Lady Bellgate Street. Monmouth—W. and J. Honeyfield, Agincourt Square; Taylor and Jones.

After leaving Gloucester the road is slightly hilly, but the surface very good. Between Ross and Monmouth there is a dangerous hill at Whitchurch. The gradient is 1 in 10. Arrived at Monmouth, the Beaufort Arms Hotel and the King's Head Hotel will accommodate the party, and Sunday will be spent according to individual tastes and preferences. On the 8th a start will be made at 10 a.m. for Tintern Abbey, which has just been purchased for the nation, and the beauties of which will call for a brief stay. The road is a capital one and the distance about eleven miles. Near the Abbey the gradient is 1 in 16, that being the steepest part of the way. From thence the trip will be continued to The Hendre, where at 1 p.m. luncheon will be enjoyed by invitation of Lord and Lady Llangattock, the return to Monmouth being *via* Raglan, a distance of nearly eight miles. During the stay at Monmouth those who are interested in industrial pursuits will be able to visit the Blaenavon Iron Works—an opportunity kindly provided by Mr. Edward Kennard, J.P.

On Tuesday, the tour will be continued to Oxford, a distance of 86½ miles. Luncheon will be taken at the Bell Hotel, Gloucester, and the following list of petroleum spirit stores will indicate the route:—

Cheltenham—Clark and Morgan, 22, Clarence Street. Eynsham—Sawyers and Son. Oxford—R. Foort, 19, Queen Street; Oxford Cycle Company, 68, St. Giles. The hotels at Oxford catering for the automobilists are the Clarendon and the Randolph.

Wednesday, the 10th, will be the last day of the tour. At 10 a.m. a start will be made for Stokenchurch and High Wycombe, where, at the Red Lion Hotel, lunch will be taken, R. C. R. Potter, the Corn Market, replenishing petrol supplies. Then *via* Beaconsfield, Uxbridge (Grainge and Grainge, 43, High Street, for petrol), and Ealing the party will proceed to the Club headquarters, *via* the Marble Arch. At Ealing Pratt's motor-spirit can be obtained from the following quartette of firms:—

Brewster and Co., 20, The Avenue, Castle Hill; Bruce, Wallace, and Co., Broadway; G. M. Foden, 132, Uxbridge Road; F. W. E. Ryde, St. Mary's Road.

In connection with the tour it is of interest to note that the outward control for London will be at the tramline station at Hammersmith, and the inward control at Uxbridge Road Station.

Otherwise all towns and villages are controls and within them passing or speeds in excess of eight miles per hour are prohibited. Controls commence where houses stand at the road side, and end where houses cease to stand at the road side. The committee of the Automobile Club hope that members will respect the law as to speeds, will use every caution in turning corners and passing through towns and villages, and will show every consideration for other users of the road, especially those in charge of restive horses.

A THORNYCROFT STEAM OMNIBUS.

HEREWITH we illustrate a steam omnibus lately completed by the Thornycroft Steam Wagon Company, Ltd., of Chiswick, for service abroad. Although Thornycroft vehicles for the transport of goods are now fairly numerous, this is, so far as we are aware, the first one that has been built for

the conveyance of passengers. The omnibus has seating accommodation for fourteen persons, carries half a ton of luggage on the roof, and averages a speed of about nine miles an hour. It is fitted with a Thornycroft water tube boiler, which may be fired with coal, coke, or oil, and a Thornycroft high-speed, enclosed, compound engine of standard design.

THE Australian Dunlop Tire Company have acquired the Australian rights in the De Dion motor vehicles.

MOTORISTS in Cheshire would do well to make a note of the fact that petroleum spirit is now being stocked by Messrs. H. Cragg and Son, of the Central Cycle Dépôt, 55, Railway Street, Altrincham. The firm are also in a position to recharge accumulators and to carry out repairs to motor-vehicles.

THE first examination of applicants for licences to operate motor-cars on the streets of Chicago was held on February 17 last. Since that time examinations have been held at stated times, and a total of 303 certificates has been granted, no less than 225 of these being for electric-vehicle operation. A large proportion of the applicants were licensed as public-vehicle operators for the two public companies located in the city.

THE postmaster of Boston, U.S.A., expects within a short time to replace the five wagons and one collection cart in use in the Back Bay district with three petrol motor-cars. The postmaster brought this matter to the attention of the Washington authorities on his recent trip to that city, and the Government is planning merely to hire the vehicles, so that the contract will call for all needed repairs to be made by the motor car companies.

IN a recent issue we referred to the fact that an early extension of the business of the Locomobile Company of America was contemplated. We now learn that in addition to the dépôt at Sussex Place, South Kensington, large premises comprising over 5,000 sq. ft. have been secured at 81, Page Street, Westminster. These new premises will be used both as works and for the storage of large two and four-seated steam cars, it being the intention of the company to have a large stock on hand so as to be able to supply vehicles at a week's notice.

A VISIT TO PARIS.

BY PHANOMEN.

TO remove any misconception that might arise from the above title, I may say at once that this is not an account of a motor-car excursion to Paris, but merely a few cursory observations made during the course of a brief visit to the French capital the other week. No, much as I might wish to make the journey to the gay city leisurely *en automobile*, that pleasant experience has not yet been mine, and I had to content myself with, at present, the more general means of conveyance—train and steamer.

Where shall I begin my cursory notes? At the Exhibition, of course, for it is there the newly-arrived visitor immediately makes his way. I do not propose to describe the motor-car exhibits at the Champ de Mars—this has already been done by the Paris correspondent of the *Motor-Car Journal*, and by means of the useful information he sent a few months ago I had no difficulty, notwithstanding the large area the Exhibition covers, in finding the automobile group in the Transportation section. And what an interesting department it is. For two or three hours I was simply lost to the outer world in examining the latest productions of Panhard, Peugeot, Mors, [Jeantaud, [Serpellet, and many other concerns

THE MOTOR-CAB STAND AT THE OPERA, PARIS

too numerous to mention. Every type of automobile is represented—petrol, electric, and steam. Of the first-named the exhibits range from motor-bicycles up to huge wagonettes and char-a-bancs. Of electromobiles one can see at a glance voiturettes, cabs, and delivery vans, while the steamers range from the huge Scotte tractors to small two-seated cars. Without wishing to make invidious comparisons, the *bonne bouche* of the whole collection is to my mind a 12 h.p. Panhard with a body by Labourdette on exceedingly novel lines. First we have the motor in front under the usual bonnet, then there comes a seat having accommodation for three persons, all three being sheltered by a glass screen which can be raised or lowered at will. Then comes another glass screen, behind which are two single seats with a passage between, this passage giving access to a seat wide enough for three persons. The body is carried up high at the rear, and although the vehicle is open at the sides it is provided with a roof extending from front to back. Needless to say it is handsomely upholstered, and as a family touring car I have, so far, seen nothing to equal it.

It has frequently been said that the motor-car has still the appearance of being a horseless vehicle—that is, a vehicle to which a horse needs adding to give an idea of completeness. However justifiable this statement may have been in the past, it can safely

be said, judging from what I saw, that those French carriage builders who have seriously taken up the automobile industry, or at least the motor-car body building portion, have not overlooked this matter, for some of their designs are quite radical departures. Jeantaud, among others, is responsible for some designs which for the moment appear somewhat strange, but which, when we have grown accustomed to them, will no doubt meet with approval.

One could spend many a week at the Champs de Mars and not see all that there is to be seen, so, my visit being but a short one, I had, much against my will, to be content with but a brief examination of the Transportation Section. Not long afterwards I found myself in the Palais des Armées, where another automobile feast awaited me. For it is in this section that the military motor vehicles, recently described and illustrated in the *Journal*, are exhibited. Grouped together in one corner of the building one finds no less than ten cars, including a Scotte steam tractor, a De Dion steam tractor, a Panhard omnibus, a Decauville voiturette for the use of the état-majors, a postal and telegraphic car by the Mors Company, a fast Mors car for the use of état-majors, a travelling office car for the use of the General Commandant, by the Peugeot Company, a postal car by the Georges Richard Company, an ambulance van by the De Dietrich Company, and a telegraph service wagon by the Koch Company. In view of the great part the motor-car has played in the recent French manoeuvres it would be interesting to know what our own War Office is doing in the way of experimenting with motor-vehicles for military transport purposes. Judging from past experience, our military authorities will wake up to the advantages of motor-vehicles, and begin to inaugurate experiments therewith, when such means of transport have found a permanent place in Continental armies. This year has been a busy one in the organisation of carnivals in aid of the war fund; a carnival to raise a fund to send a commission from our War Department to France, to read, mark, learn, and inwardly digest what is being done by our neighbours, would have an object no less meritorious and useful.

So much for the Exhibition, time unfortunately not permitting a visit to the annex at Vincennes. And now what about the automobile movement in Paris. I was told not to expect to see a very large number of cars, for the leading lights of the automobile world are, just now, holiday bent, touring in various parts of France, Switzerland, Italy, and even Algeria. Be this as it may, there are still sufficient left at home to cause one to make odious comparisons with London. Hardly a moment passes but a motor-car or cycle whizzes by as one promenades the boulevards or streets, for, independent of the many private vehicles, there are large numbers of both electrical and petrol cars plying for hire. At almost any of the cab stands one is sure to find three or four motor-vehicles awaiting a call. The accompanying illustration, reproduced from a snapshot of the stand at the Opera House, shows both electric and petrol cars. The electrics, which form the great bulk of the motor-cabs in use, are very similar to those which ran for some time in London, while the petrols are small Peugeot cars. The speed at which the cars, both private and public, fly about on the smooth roads of the boulevards would raise the hair of the average London policeman, and cause the correspondence columns of the daily papers to be filled with letters on the subject of the excessive speed of motor-cars, or the slow speed of our handsome horse-drawn "growlers."

On the Sunday afternoon I made my way along the Champs d'Elysées to the Bois de Boulogne. Just as in London, the toot-toot of a horn gave the signal that a motor-car was approaching, but instead of an occasional toot-toot, as at home, one tooter had hardly got out of hearing than another took its place. My arrival at the Bois was somewhat delayed, for the Avenue de la Grande Armée intervened. This thoroughfare is the Holborn Viaduct of cycle and motordom in Paris, and with almost every other dépôt devoted to automobiles the cause of the delay is not far to seek. It was consequently somewhat late when I found myself within the Bois. Yet, despite the fact that the dining hour was close at hand, the automobiles turned up in good force. Taking a seat near the Porte Maillot I counted within the short space of ten minutes no less than fifteen cars, ten voiturettes,

fifteen trikes and quads, and a Bollée. The way the cars and cycles were handled was admirable; as for the speed—well, all I can say is that had they been dashing through the Marble Arch at the same speed as they passed through the Porte Maillot the drivers would have all had to appear at the police-court on the following day, on a charge of furious driving. Some of the cars had only been out for a short spin, but the dusty appearance of several indicated that they were returning from a long trip. And here I may mention a dust-catching device which appears to be coming into use by *chauffeurs* in Paris. One knows what a dust is created at the rear of the car when travelling at a fair speed. To prevent this rising and inconveniencing the rear passengers, two poles are being fitted, projecting from the top of the rear portion of the body parallel with the ground. Across these poles, which project about a yard, is stretched a cloth, usually of a colour similar to that of the carriage body. I saw three or four cars fitted with the arrangement, and while it did not strike me as being very elegant, yet I have no doubt that it fulfils its object of preventing the rear passengers being smothered in dust. And if motor-cars and cycles are being largely used in Paris, it is only natural that facilities for the storage and repair of the same should be available. And so they are. *Garages*, where one's car or cycle can not only be stored, but cleaned and repaired when necessary, are rapidly increasing in number, while accessories and *essence* are to be found on every hand. As an indication of this, the fact that such articles as sparking plugs, current interrupters, etc., are included in the trays of goods exposed for sale outside one of the large miscellaneous bazaars on a leading Boulevard may be instanced.

The Parisian no longer wastes time in debating the question as to whether the motor-car has come to stay and whether he should defer his purchase lest the present vehicles be superseded by improved designs in time to come. Having settled the first question in the affirmative, he is taking—no, has taken, the motor-car as it is. True, it may not be perfect as yet, but the extensive adoption they have met with has shown the weak points of the vehicles that have hitherto been built, and as these are discovered attention is devoted to their elimination. Thus both makers and users of motor-vehicles are working hand in hand in the task of evolving the ideal automobile. In England, on the other hand, the old spirit of conservatism still prevails, many possible users of motor-cars, who would undoubtedly find them more economical than their present means of transport and conveyance, still holding back from taking the step of adopting horseless vehicles.

On all hands one finds in Paris evidences of the hold the automobile has already obtained on the people. Used both by the Government and in the public service, those who cannot afford a vehicle of their own are able to, and do, take advantage of the facilities offered them for a drive *en automobile*, and even the children can, for a 10 centime piece, have a ride in a motor-car round-about, one of which formed a leading attraction at the recent fair at St. Cloud.

While there can be no doubt that the automobile movement in England is progressing, its progress is not so rapid as I, like

many others, would like to see it, and a visit to Paris only emphasises the fact that we have still a long way to travel ere automobiles and automobilism become such general features as they are at the present time in France.

EXPERIMENTS with a motor street-sweeping machine are again being carried out in Paris.

WE hear that Lord Saville, of Rufford Abbey, Notts., will shortly be the possessor of a 6-h.p. Daimler.

THE Marot-Gardon voiturette, illustrated and described in a recent issue, is now being fitted with a 6 h.p. motor.

A MOTOR-CAR has just been despatched from France to M. Cagnan, director of the Phosphate Mines, at Gafsa, in the south of Tunis.

THREE 50 h.p. Napier cars will probably be made for next year's Gordon-Bennett race. They will be ready in March, and one will be for Mr. S. F. Edge.

THE well-known Soncin motor, by means of which so many tricycle records have been broken, is now being made by Messrs. Ouzou and Co., of Paris, in larger sizes up to 6 and 8 h.p., these engines being, of course, water-cooled.

THE cry of the members of the London Salvage Corps when going to fires will be heard but a little while longer, for a gigantic cycle bell is to be fitted to the splash-board of the engine and worked by the driver's foot.

ON Wednesday morning a De Dion voiturette skidded on Waterloo Bridge, and ran into a van that was passing. Strange to say, the incident has not yet been exaggerated into a "Motor-car smash" by the Fleet Street liner.

THE other day a bicycle ridden by Mr. Wm. Chapman, of Raynes Park, collided with an

automobile driven by a gentleman from Ealing, near Window's Bridge. The cyclist escaped with a few bruises, but his machine was somewhat damaged.

THREE Scotch motorists, Messrs. A. K. Dempsey, J. S. Miller, and T. R. Outhwaite, have just completed a trip from Birmingham to Edinburgh on motor-cycles. Travelling *via* Derby, Nottingham and Newark, the North Road was joined at the latter place, the journey being continued *via* Doncaster, Selby, York, Newcastle, and Berwick.

THE Dow Portable Electric Assistant Co., of New York, have just placed on the market a three terminal coil, a four terminal and a combination coil. The four terminal coil, made especially for motor-bicycles, is only 10 inches long and 2½ inches in diameter, and can be fitted snugly under the top bar of the frame. The combination battery and coil measures 8 by 11½ by 3½.

SOME twenty or thirty members of the Cycle Engineers' Institute accepted the invitation of Messrs. Thomas Firth and Sons, Limited, to visit their steel works at Sheffield on the 27th ult. The next general meeting of the Institute will be held at Coventry on the 11th inst., when Mr. C. T. Crowden will read a paper on "Motors and Motor Cars, their defects and remedies."

A PARISIAN ELECTRIC CAB.

THE DAIMLER MOTOR AND TRANSMISSION GEAR.

IN the last issue of the *Automobile Club Notes* there appears a letter on the above subject from Mr. W. Worby Beaumont. As the question is of interest to the large and ever-increasing number of users of motor-vehicles of the Daimler type, we reproduce the letter below:—

"A discussion has been raised as to the sufficiency of the gear of a 6-h.p. Daimler car for use on a 12-h.p. car. The question was raised by Mr. Ernest Hutton, who added a 6-h.p. to the front of his 6-h.p. car, thus converting it into a 12-h.p. car without making any change in the gear. On the one hand it is argued that if the gear is sufficient for the 6-h.p. motor with its frequency and intensity of impulse, then it must be sufficient also when the second motor is added, because the intensity of the impulses remain the same, only the frequency being altered, the impulses of the two motors never being simultaneous.

"On the other hand it is argued that inasmuch as the gear with the added motor conveys 12 h.p. instead of 6 h.p., and imparts to the chain double the pull, the stress upon the gear must also be doubled. Both these arguments are in part true, but both are incomplete. If the gear received the explosive impulse direct, then it would probably fail by broken teeth, even with one engine, and the addition of the second engine would

FIG. 1.—GENERAL VIEW OF MEYNIER-LEGROS ELECTRIC CAR.

only expedite the failure by introducing double the number of impulse shocks in a given time. If the gear were made originally strong enough to receive the direct impulse, then the introduction of the second engine would only add to the wear by doubling the wear effort of work done.

"Inasmuch, however, as a fly-wheel is interposed between piston and gear, its inertia has first to be overcome. It receives the piston impulse during a small part of a revolution and, acting by momentum, serves as an accumulator which gives off the absorbed work in a large part of one or more revolutions. The intensity of the shock is proportionately lessened, and may be looked upon as spread over a number of the gear teeth instead of one, as would be the case in the absence of the fly wheel.

"The impulse effect per impulse thus remains unaltered by the addition of the second engine. The latter, however, doubled the number of impulses, and the energy imparted to the fly-wheel is doubled, and it does double the work on the gear, and the wearing power is doubled. The actual or the extra wear may, however, be masked, or may be less than that due to doubling the engines in a car which generally runs in easy country. The 5 or 6-h.p. motor may have been nearly enough, and the two motors may together, as a rule, only do 7 or 8 h.p., and the wear, therefore, not be sufficiently increased to make it perceptible in a short time.

"In changing speed, however, with wheels which slide into

gear laterally as in most cars, the damage done when the wheels dig each other's tooth corners, or only slip part way into mesh, may easily be more than doubled with the double motor in the hands of an unskilful driver."

THE MEYNIER-LEGROS ELECTRIC CAR.

AMONG the electric vehicles exhibited at the Champ de Mars, Paris, is the car shown by Messrs. Meynier and Legros, of which illustrations are given herewith. Carrying some of its Fulmen accumulators in a case placed on the fore part of the frame, this carriage consequently resembles somewhat in appearance the ordinary Panhard type of petrol car. Its motor, which weighs about 100 kilogrammes, develops 8 h.p., and is supported from the frame and back axle. It drives on to each of the back wheels through the medium of a single set of

FIGS. 2 AND 3.—ELEVATION AND PLAN OF MEYNIER-LEGROS ELECTRIC CAR.

gear, consisting of leather and iron gearing, with an internally-toothed aluminium wheel, the teeth of which are of bronze. The motor works at 80 ampères, and the controller switch permits of six forward and reverse speeds. Three electric brakes for both forward and backward driving are also available, as also is a very powerful pedal brake, the application of which cuts off the electric current in addition to braking the car. The speed is controlled by a handle on the steering column underneath the hand-wheel. The constructors claim that their vehicle can run from 80 to 100 kilometres, at an average speed of 24 kilometres per hour, without recharging, and that it can ascend hills of one in twelve at a speed of 10 kilometres per hour. Wheel-steering on the Lavenit system is employed. Summed up, the car is a smart and an attractive one, and the makers should find a ready market for their production.

HERE AND THERE.

VERY gravely and seriously do many of the gentlemen sitting on rural councils inveigh against the motor-car as though it were an unwieldy monstrosity indeed. That may be forgiven them—at their time of life. But when they leave a motor and attack the motorist I feel inclined to write something.

It is alleged that automobilists are uncouth, ill-mannered creatures whose minds cannot rise above mechanical things and whose manners are those of the peacock combined with the pig—the strutting proudness of the bird associated with a grunting disposition that inclines to insolence. They decline to stop when asked, they run over ducks with glee, and would knock ladies down without stopping to inquire the damage done. Altogether, according to several local magnates, automobilists are a bad lot. Such accusations seem to invite the *tu quoque* argument. Are there uncivil drivers of horse-drawn vehicles? Do coachmen ever get on the wrong side of the road? Have horses ever been seen to gallop along a road to the inconvenience of the public? Of course these things have happened, and even in the most immaculate set of drivers that could be produced such black sheep would be found.

THERE are a few automobilists who do not do the things they ought to do, and there are some whose manners need polishing, but if those who make such assertions as those mentioned would only think awhile the silliness of general attacks on such slight foundations would be apparent. There would be less friction if all who drive horses or motor-cars and who ride bicycles would go through a thorough training in passing traffic. When cycles were introduced their riders were ignorant of steering through traffic; clubs and experience have removed the lack of knowledge, and similar institutions are proving of equal service in connection with automobilism. It is not a very easy matter to steer clearly through traffic, and both motorists and drivers of horsed vehicles have to learn their way about. But to say that one is worse in that respect than the other is, as Euclid observed on more than one occasion, “absurd.”

THE other day I took a short trip through London with young Cusins, who was a familiar figure on the Napier car during the 1,000 mile Trial. We were on a Clement-Panhard voiturette that ran easily and well, proving itself a very comfortable and roomy vehicle. Voiturettes are frequently regarded as carriages for two persons and no baggage. But the long wheel-base of this voiturette allows for a fair amount of luggage as well as its complement of humanity. From Holborn Viaduct we went into Holborn, and the way the car was steered—particularly in that portion of the road between Gray's Inn Road and Chancery Lane—afforded testimony to the ability of the driver in getting through traffic. On the wood pavement of Oxford-street we went at a good pace, and then into Regent-street and over that wretched road in Portland Place. Why is that not paved with wood, or, at any rate, why is the surface not kept level and decent?

ALTHOUGH trips through the parks are familiar enough, a spin right round Regent's Park is not so usually given in connection with trial trips. It is a short run over a not too well prepared road, and presents an array of fine houses on the one hand and a most delightful display of foliage on the other. But when the road has been sprayed with rain for a good two hours and the wind is against the riders, the conditions are not wholly faultless. For the mud attacks one in the rear, and the backs of passengers become of a khaki hue that shows up very conspicuously on black raiment.

SHOULD anything go wrong with motor-cars when near Sandgate, Mr. J. Maltby will be pleased to set them right. He has had two years' experience in such work. Mr. Maltby is not a cycle agent, but served an apprenticeship as an engineer with Messrs. Maudslay, Sons, and Field. He has also had engineering experience with Messrs. Samuda Bros., Messrs. Penn and Co., and Messrs. Yarrow. In addition to doing repairing work he stocks petroleum spirit.

MOTORISTS going north will find the run from Sheffield to Bridlington a very enjoyable one of eighty-one miles. Doncaster is the first town of any importance that will be reached, and then there is a good road to Hatfield, over the canal at Thorne, and along a level surface to Rawcliffe. From thence the Goole road is followed for three miles. Rather more than forty miles from Sheffield is Howden, noted for its horse fair, and after a while a good run over the Yorkshire Wolds, through Middleton and Dalton, leads the motorist to Driffield. After that a series of interesting villages is passed through, until Bridlington Quay or Sheffield-by-the-Sea comes in sight.

NEARLY a year ago I wrote a fanciful sketch of the time when men would go to and from their work on automobiles. That time seems to have come in one city of California, where a leading firm of engineers has secured a passenger automobile carrying twenty-five people, which will be employed to take their workmen from home to factory, and from factory to home. It will call every morning between 6 and 7 o'clock at given points in the city, to pick up and carry the employees to their works. In the evening the car will return the men to the places at which they were collected in the morning, or, if possible, direct to their homes. This service has been established because of the absence of a tramway in the district in which the men live.

ON the lawn of a well-known patron of automobilism I recently saw several motor-cars careering about, and succeeded in getting a photo of one—a Motor Manufacturing Company's

Marlborough phaeton — with Miss Pursehouse and another lady and Mr. Lyons Sampson in the rear seats, Miss Ledger being beside the driver.

THE recent trip of the English Motor Club to Luton demonstrated that there are many automobilists to the north of London. Further evidence comes in a simultaneous notification from Messrs. Horle and Co. of Harpenden, and Mr. J. L. Thomas of High Barnet, that they can execute repairs to motor-vehicles. The former has also accommodation for the storing cars.

MOTOR-CARS have been useful in the elections, but they have occasionally led to platform gibes that have not been appreciated by the other side. One candidate has just declared that the only thing conspicuous about his opponent was that he had a motor-car. That was a very useful class of vehicle, continued the speaker, but somewhat eccentric. Comparisons between the candidate and his motor-car naturally followed.

HERE is an extract from a very luminous report on the trade of Coventry appearing in the *Birmingham Daily Post*:—“Business on the whole is not brisk. The motor industry is fairly active, and some of the cycle firms are well employed, but others are not.” Just fancy! “Some of the cycle firms are well employed, but others are not.” What a contribution to our knowledge of the state of business.

LOLLIUS.

CORRESPONDENCE.

EXPERIENCES IN WALES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In reference to Mr. Geipel's letter in your issue of the 22nd ult., I feel it my duty to say that wherever I have toured in Wales on my Bollée or Daimler I have received nothing but the greatest courtesy and kindness. Indeed, Wales seemed to me to be an ideal motor-touring place. As regards the Welsh people, I have always found them very kind and hospitable. I sincerely pity Mr. Geipel in his affair at Llanrwst, and shall personally carefully avoid it, but I do not think it fair to condemn all Wales for one town's persecuting folly. Yours truly,
Northampton, 1st October, 1900. ALAN HICKMAN.

THE COST OF PETROLEUM SPIRIT.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I read with interest the account of Mr. Knight's trip from Farnham to Bath in your issue of the 15th ult. With regard to the cost of petroleum spirit, I notice that Mr. Knight remarks that "a gallon of petrol can be bought for one shilling and threepence. . . . Of course when petrol is purchased in out of the way places in small quantities, eighteenpence is often charged for it." I am not going to dispute this, but I think it is a little unfair to people in the country to give the price of petrol so low as this. I am going to stock Carless Capel's petrol, and have just got their prices. I find with carriage here it just costs me 1s. 6½d. per gallon. Now, can any sensible man pay his way and sell this even at 1s. 8d. and take risks, etc., in stocking petrol? Yours truly,
Grove Cycle and Motor Works, J. E. JOHNSON.
Wilmslow, October 1st, 1900.

STEAM CARS IN ENGLAND.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I was very pleased to see your paper referring to the Serpollet steam car. I have been connected with these cars since their introduction into England, and have been on several other motor-carriages. In my opinion, for simplicity and safety, there is none to compare with the Gardner-Serpollet; it is impossible for a novice to get on the car and explode it. One difficulty has still to be overcome in England—that is, getting things repaired and tempered to withstand the heat. I agree with you that before very long we shall see a good many steam carriages running in England. I am at present running the identical Serpollet car in the country that was exhibited at the Agricultural Hall in 1899. As the vehicle has been in continuous operation since that time, I think you will agree that the car has proved its qualities. Yours truly,
York, October 2nd, 1900. F. H. H.

CAR FOR SPAIN.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I am wanting a motor-car, and as I have an electric light installation on my premises, I think I cannot do better than buy an electric car. Before doing so, however, I should like to have the views of any of your readers on the subject. Yours truly,
Lisbon, September 27th, 1900. S. F.

FORTY MILES AN HOUR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I notice Mr. Jarrott has apparently relinquished the idea of making his forty miles an hour record on the Crystal Palace track, and intends to succeed on some new course at Canning Town. Is this quite fair? Up to the present the Crystal Palace track has been the recognised place for such records, and if we are to have several tracks for record making, discrepancies in the value of performances are bound to result.

Let the Automobile Club declare on which track records shall be made, and let all racing men stick to that one course.
London, October 2nd, 1900. Yours truly,
A. B. C.

RIGAL'S MOTOR-TRICYCLE RECORDS.

THE records recently made by the motor-cyclist, Rigal, and duly chronicled in last week's issue of the *Motor-Car Journal*, have not been permitted a lengthy existence, for on September 25th, at the Parc des Princes, the same rider improved considerably upon them, and set up new figures for a number of distances. It is extremely doubtful whether these fresh records will be beaten upon the Auteuil track, for the banking is not sufficient to permit of greater speeds being accomplished, and Rigal may be considered fortunate to have come through his trial without mishap. In taking the sharpest corner the one wheel of the machine lifted clear of the track each time, and this, too, in spite of the fact that the rider had cut off the current. How the tires resisted the enormous strain to which they were subjected was a source of astonishment to the spectators, the majority of whom had congregated at the most dangerous spot in anticipation of seeing Rigal come a prodigious cropper. It is a curious trait of the human nature which permits men, who cherish no sentiment of ill-feeling against the possible victim, to gather together at the spot most likely to witness an accident, with a sort of half wish that something will happen. But so it is, and the other Tuesday afternoon a crowd of cyclists, who were training at Auteuil, as well as many *chouffeurs*, assembled at the sharpest corner of the track to see a mishap. Fortunately this did not happen, and the spectators were only called upon to cheer little Rigal upon the completion of his performance. The machine ridden was a Perfecta built by MM. A. Darracq and Cie., of Suresnes, and fitted with two Buchet motors, each developing 6 h.p. A 12 h.p. tricycle! The days of the one and three-quarters are certainly over. Monsieur Gaudichart, who usually figures as timekeeper on these occasions, again officiated, and *en route* Rigal set up the following figures:—

The kilometre with flying start, 47½sec., which represents a speed of 77 kilometres 500 metres per hour.

The mile with flying start, 76½sec., which represents a speed of 75 kilometres 600 metres per hour.

Ten kilometres with flying start, 7min. 58½sec., representing a speed of 75 kilometres per hour.

Twenty kilometres with flying start, 16min. 11½sec., representing a speed of 75 kilometres per hour.

The entire official return is as follows:—

kilo- mètres.	min. sec.	kilo- mètres.	min. sec.	kilo- mètres.	min. sec.
1	1 4½	11	9 2	21	17 10½
2	1 52	12	9 50	22	18 0½
3	2 40	13	10 38½	23	18 50
4	3 28½	14	11 26½	24	19 39½
5	4 16½	15	12 15	25	20 30
6	5 3½	16	13 3½	26	21 20½
7	5 51	17	13 52½	27	22 10½
8	6 38½	18	14 42½	28	23 1½
9	7 26½	19	15 31½	29	24 4½
10	8 14	20	16 21½		

MRS. VICTORIA CLAFFLIN WOODHULL, of the *Humanitarian Review*, has, we understand, joined the ranks of the automobilists.

THE Mid-European Motor Car Club held its annual meeting in Berlin, on Sunday, the 30th ult. The club, which started with fifty-one members in September, 1897, has now a membership of nearly 600.

MR. JOHN BRISBEN WALKER, a well-known American *chouffeur*, ascended Pike's Peak, Col., recently in a motor-car. He did not go to the very top, but made an ascent of 11,000 feet, thus making a record. The road was in very bad condition, or the top would have been reached. The descent is said to have been an exciting one.

THE TALE OF A TOLL.

WHAT fun motorists can have with tollkeepers who have to open the way to motor-cars for the first time! "And what exorbitant charges are made for the passage of such vehicles!" says the automobilist who vainly imagined he would not be classified other than as an ordinary person, vehicle or thing.

Mr. Alf. Vare, the captain of the King's Lynn and District Wheelers' Club, has had a little adventure which is worth the telling, and may lead others who have suffered to send us accounts of their struggles with tollmen. With two or three friends, like himself mounted on motor-tricycles, he was recently enjoying a trip through the Fen country—that long stretch of level roads with hardly a hill and scarcely a gradient; certainly nothing calculated to deter the automobilist from challenging any other form of locomotion. On the road between the cathedral city of Peterborough and Whittlesea is a tollgate. The tollhouse is, like most buildings of its kind, unpretentious and the man in charge has the usual uniform of shirt-sleeves. Arriving at the gate, the motor-cyclists found it was open—a trap having immediately preceded them. But the tollkeeper rushed into the road and stopped their progress. With his hands raised and his face presenting a scared appearance he was a sight for gods and amateur photographers. It was evident he had never seen a motor-tricycle before. Observation satisfied, a look of melancholy settled on his countenance as the thought of a new problem in rating crossed his mind.

To show they were merely human, the riders dismounted and asked the man the price of the toll. He was quite non-plussed, said he did not know, declared he would have to find out, etc. But how to consult his bookish authorities and keep an eye on the travellers was a dual position he did not relish. At length a bright thought struck him and he went indoors, sending his wife outside. She watched and he consulted.

Meanwhile, the motorists prowled around and read the list of tolls on the board. The last item was "Bicycles and tricycles of any kind, 2d." That decided them as to their future course. They each got 2d. ready and awaited the return of the tollkeeper, while Mr. Vare secured a favourable spot from whence to "snap" the scene when payment was tendered—with the result that the accompanying picture adds interest to our columns.

The man demanded 9d. each for allowing the motor-tricycles to pass. The riders referred him to his notice-board—a photo of which was taken by Mr. Vare to the utmost amazement of the

ENCOUNTER WITH A TOLLMAN.

poor fellow in charge. The board is fairly antiquated, and has the appearance of having served since the early days of the Queen's reign. Insisting that the clause "of any kind" included tandems, sociables or motors, the motorists at length conquered and with great reluctance the man accepted twopence from each, together with their cards.

And then the triumphant riders pursued their way with

lightness of heart and smiling countenances, and as they went into a field to rest after their encounter a further photograph testified to their satisfaction with the experience through which they had

THE TRIUMPHANT MOTORISTS.

passed. Riders of motor-tricycles between Peterborough and Whittlesea must remember that there is a precedent for a charge of 2d.

A NEW society has just been formed at Versailles to be known as the Moto-Club de Seine-et-Oise.

WE understand that the plant, etc., of the Liquid Fuel Company, at Cowes, Isle of Wight, will be sold by auction at the end of this month.

MESSRS. DELAUGÈRE AND COMPANY, of Orleans, are now making a 3 h.p. water-cooled Romain motor, in addition to the air-cooled engine described in our issue of June 16th last.

AT their premises in Shaftesbury Avenue the Motor-Car Co. have a new 6 h.p. motor-car with "tonneau" body of fine finish.

MESSRS. DENNIS BROS., of Guildford, have taken possession of their new premises at the corner of Onslow Street and Bridge Street. They intend to make a speciality next season of a four-seated car with a De Dion motor.

ON Friday, the 5th inst., the sale conducted by Mr. Ernest Owers at Rosemont-road, Finchley-road, N., will include a 4 h.p. touring-car, 3 h.p. Bollée, 6 h.p. Parisian Daimler, an Enfield quadricycle, a 3 h.p. Benz Ideal car, and several motor-cycles. Another sale is announced by Mr. Owers for November 2.

ON Saturday, the 22nd ult., the members of the Automobile Club of America enjoyed a run to the grounds of the Larchmont Yacht Club, Larchmont, New York, where they were the guests of that club at their annual "clam bake," whatever that may be.

AT Falkirk last week, before Sheriff-Substitute Liddell and a jury, Donald Mackenzie, motor-car driver, Melville-street, Falkirk, was sentenced to two months' imprisonment for having, on the road at Carron, assaulted Matthew Halfpenny, nine years, by kicking him on the right leg and fracturing his thigh bone.

MR. FRANK F. WELLINGTON, of St. George's Square, N.W., is now carrying a stock of parts of Panhard and Levassor, Aster, De Dion, and Daimler motors, and is making a practice of supplying any parts required by return of post. He is also now making a speciality of the manufacture of wheel steering, and the fitting of Daimler and other cars with this favourite arrangement.

A DAY or two ago the motor-car belonging to Mr. F. C. Gould, of the Windsor Hotel, Barry Dock, met with a singular mishap. The car was being driven along Court Road, Cadoxton, in the direction of Barry Dock, and when nearing Hannah Street the driver found himself placed in an awkward position. To avoid running over a child he changed the course of the car, and came in contact with the district council's steam road roller, which was passing at the time. The local paper reports that considerable damage was done to the motor-car by the collision.

MOTOR-CARS ON THE CONTINENT.

The Moto-Club de France.

At the committee meeting of the Moto-Club de France held last week it was announced that the membership now stood at 658. It was decided to organise a race for motor-vehicles propelled by alcohol motors for the 28th inst., the course being from Paris to Rouen, via St. Germain, Mantes, and Gaillon—a distance of about 136 kilometres. Three prizes of respectively £40, £12, and £8 are being offered. So far three entries have been received.

A Motor-Car Auction.

A SALE by auction of motor-cars was held at Chéri's Mart at Neuilly, near Paris, last week. There was, however, but a light attendance, and the result of the proceedings was that out of twenty-six machines offered but few were sold. It is surprising that, with M. Raymond Chéri Halbronn's new system of warranty, dealers do not step in or agents buy for foreign account, as when MM. Charron, Girardot, and Voigt's experts have passed a machine as being in "good going order," the buyer can be sure that such is the case. Of the automobiles which found new owners were two Panhard and Levassor omnibuses, Baron Henri de Rothschild giving 2,250fr. for the first and M. Vigna 3,850fr. for the second. A "duc" by the same makers was secured by M. Barbier for 3,050fr. These were all warranted. Vicomte d'Arsigny's Panhard 4 h.p. phaeton went to M. Waucquez for 2,050fr.; M. Carriat secured M. Souvestre's 7 h.p. Mors car for 1,000fr., and M. Germe purchased M. Pinon's little voiturette for 1,050fr. Bidding for an electric brougham by Jeantaud was run up to 10,000fr., at which figure it was bought in.

Motor-Cycling in the Alps.

MOTOR-CYCLING in the Alps is apparently to become a popular pastime. The other day an Italian motorist, Signor E. Columbini, of Pinerolo, set out from that town on a 1½ h.p. tricycle and succeeded in mounting the Colle di Sestrieres, 6,670ft. above the sea.

Another Long-Distance Race in Germany.

IN view of the success of the recent automobile race between Berlin and Aix-la-Chapelle, the West German Automobile Club is now considering the organisation of a race about twice as long. No definite plans have been made as yet, but Insterburg-Aix-la-Chapelle is spoken of as the probable course.

Track Racing in Berlin.

THE automobilists in Berlin are following Ostend's example, and are organising a motor-car track racing meeting. The use of the horse-trotting track of the Trab-Verein, in the west end of the city, has been obtained, and here it is proposed to run off a number of races, both for amateurs and professionals, on the 21st inst.

The "Poids-Lourds" Competition.

So far only four entries have been received for the Poids-Lourds, or heavy vehicle competition, which, under the auspices of the Automobile Club, starts on Monday next, the 8th inst. Messrs. Panhard and Levassor and M. Pantz, of Pont-à-Mousson, have entered petrol wagons, M. H. Say an electrical wagon, and M. Le Blant a steam wagon. The French Minister of War has delegated several officers to follow and report upon the competition.

MOTORISTS touring in Dingwall can obtain motor-car spirit and lubricating oil from Mr. A. Henderson, 5, High Street.

IGNITION AND IGNITION TROUBLES.

(Concluded from page 513.)

IF the engine is started by a ratchet crank, it is quite desirable that the first explosion should not occur before dead centre, as otherwise the engine may start in the reverse way, against the exertion of the starter, which may lead to accident. But to obtain the maximum of power from an engine running at high speed it is essential that the spark pass before the dead centre. The combustion of the explosion mixture begins at the point where the spark passes, and from there spreads to all parts of the combustion chamber. But the propagation of the flame takes some time and the pressure in the cylinder rises therefore gradually and not instantaneously to its maximum value. This is well seen from an indicator card taken from an engine running at high speed. The effect of the lag in the process of combustion is to shift the point of maximum pressure, which in a slow-speed engine lies near the beginning of the stroke, further ahead. It may thus happen that the pressure at the time the exhaust opens is greater than when the piston starts on its forward course. If such be the case, then the ignition should

FIG. 5.

take place at an earlier period to obtain the maximum power. To satisfy the two requirements just mentioned it is necessary to have an adjusting attachment on the igniter, by means of which it can be given a lag when starting and a lead when running at full speed. This adjustment may be effected either by hand or automatically, the latter being the more desirable arrangement.

The writer prefers to locate the igniter in the valve chamber, where the draft of the incoming charge may cool it. This lessens the danger of burning the contact parts and keeps the temper in the spring if there be one inside the combustion chamber. It is sometimes suggested that the explosion might be more instantaneous and more effective if the ignition took place in the cylinder proper; but if the ports are large, as they should be, there is no loss of power from this source.

The difficulties with igniters are many, and the writer has heard the remark that if your gas engine stops, the first thing to try is the spark. The faults to which ignition outfits are liable and which will prevent them from working properly are the following: The source of current may run down, the connecting wires may loosen or break at some point, the connecting wires or insulated electrode may ground, the contact of the electrodes may become burned and not permit the passage of the current, the springs may break or become weakened to such a degree as not to produce a good metallic contact. Finally, it may happen that in readjusting the igniter it may be timed wrong.

The running out of the batteries on the road is a source of great difficulty, but this and the remedies therefor have been discussed and need not here be gone into. Going over to the second of the faults mentioned, it may be stated that it often occurs that a binding screw rattles loose, or that a connection wire is broken, the latter being mostly caused

by carelessness in work around the engine. The loosening of the binding posts can only be guarded against by seeing that they are firmly screwed down when the connections are made. For the connections between batteries, spark coil, and engine incandescent lamp cord of one of the larger sizes should be used. The ends fastening to the binding screws should be soldered. The lamp cord consists of a large number of fine wires, is very flexible and not easily damaged.

A ground on the insulated part of the igniter is usually a puzzle for the inexperienced motor operator. When it has been found that no spark passes when the engine is turned over by hand, the following proceeding should be gone through with to locate the difficulty. Turn the crank to a point where the electric circuit should be complete—that is to say, nearly up to the point where the spark should pass. Now detach the wire from the insulated electrode and brush it over this electrode. If there is a spark the batteries, coil, and connections are intact and insulated part of the igniter is grounded—i.e., in metallic connection with the engine frame. If, however, there is no spark, then the electric circuit is incomplete and the break should be looked up. The stationary electrode of an igniter should always be the insulated one. Occasionally both electrodes are insulated, and in this case the grounding of one will not interfere with the working of the igniter. It is, however, not advisable to insulate the movable electrode, as the pressure and strain due to the power applied to it would soon throw it out of line and eventually short circuit it. The igniter springs must always be kept in good condition, especially in such igniters where the pressure of contact depends upon the force of these springs. Coming now to the last-named source of trouble, the improper timing of the igniter, it may be that the mentioning of the possibility of such an occurrence provokes a smile upon the countenance of some reader, as even the novice knows that a proper timing of valves and igniters is necessary to secure good results with an explosive motor. The writer would not have mentioned this subject were it not for the fact that he has actual knowledge of cases in which days of time of people who claimed to be more than mere amateurs were wasted simply because in reassembling an engine they had meshed the valve operating gears incorrectly. Such a mistake as this should ordinarily be easily discovered; but when, as in one of the cases above referred to, some other changes or additions are made at the same time the valve operating gears are dismounted and reassembled, the cause of the difficulty is likely to be assigned to these new parts.

It is always well to have a plug directly over, or at least somewhere near, the place where the spark occurs, so that, when withdrawing this plug and turning the engine by hand, the spark may be observed. In larger engines a plug with a small mica window is sometimes placed directly over the igniter, thus permitting the spark to be observed while the engine is in motion and without removing the plug; but it is hard to find room for such a device in a small engine.

The negative electrode of an igniter is not affected nearly as much by the action of the spark as is the positive electrode, and in connecting up an engine the electrode which is easiest replaced should therefore be made the positive one. If primary cells are used for ignition the positive terminal is the one connected to the carbon plate.

The igniter circuit should be provided with a hand switch so located that the circuit may be opened and closed by the driver from the seat. If the engine is of the multiple-cylinder type this switch should preferably be made so that any one and all of the igniters can be switched in at will, which greatly facilitates the testing of the cylinders. Fig. 5 shows a form of switch for a double-cylinder engine which will permit these various connections. If the switch lever is held down by a shoulder screw with a butterfly head it may easily be withdrawn when having the vehicle stand in the street, and thus protect it against mischievous designs.

The jump spark, which is very much used in France, has not as yet become very popular in America. The objection usually made to it is due to the difficulty of insulating against the high pressure necessary to produce a spark between terminals 1-16 in. or so apart. The outfit is also considerably more expen-

sive than the simpler forms of contact spark igniters. Jump spark igniters require a coil with two windings, and induction coil. One of these windings, called the primary, consists of a large number of turns of very fine wire. There is no electrical connection between the two windings, the current from the primary or other source of current supply is sent through the primary winding and interrupted at the proper moment by a switch or commutator driven from the crank shaft. When the circuit is broken the current suddenly ceases in the primary, which by inductive action produces an electro-motive impulse in the secondary winding. The terminals of the secondary winding are connected to the electrodes of the igniter. The electrodes of a jump spark igniter are sometimes both insulated, while again, one is grounded. The insulated electrode or electrodes pass through a bushing of insulating material held in a metal plug screwing into the wall of the combustion chamber. The electrodes have platinum points and they are bent so as to come very close to each other. The electro-motive impulse in the secondary coil will send a spark across the gap intervening between the two electrodes, and this spark ignites the mixture.

Where the engine has a single cylinder only, the current has to be sent through the primary coil once for every two revolutions of the motor, and where it has a double cylinder twice. These current impulses must, of course, be spaced the same as the explosions. For a multi-cylinder engine we also need a commutator, by means of which the spark can be distributed to the various cylinders. The adjustment for timing the spark of a jump-spark igniter must be made on the commutator making and breaking the primary circuit, and consists in giving an angular motion to the stationary part of the commutator.

STEAM ROAD VEHICLES.

THE success of steam in connection with the conveyance of heavy traffic by motor-vehicles, and the recent trips of the Prince of Wales on a steam car, have revived interest in a subject which, seventy years ago, was attracting considerable attention in this country. The Parliamentary Committee had made inquiry in 1831 into the matter and had come to the following conclusions:—

1. That carriages can be propelled by steam on common roads at an average rate of 10 miles per hour.
2. That at this rate they have conveyed upward of 14 passengers.
3. That their weight, including fuel, water, and attendants, may be under 3 tons.
4. That they can ascend and descend considerable inclinations with facility and safety.
5. That they are perfectly safe for passengers.
6. That they are not (or need not be), if properly constructed, nuisances to the public.
7. That they will become a speedier and cheaper mode of conveyance than carriages drawn by horses.
8. That, as they admit of greater breadth of tire than other carriages, and as the roads are not acted on so injuriously as by the feet of horses in common draught, such carriages will cause less wear of roads than coaches drawn by horses."

Vested interests prevented further experiments being conducted in that direction and later years have seen splendid developments of the petrol motor, but the long-continued search after steam vehicles for ordinary roads is by no means over.

ALTHOUGH Hyde Park is now practically deserted by carriage folks, automobilists are still using the circle for purposes of fresh air. The other day seven or eight vehicles were seen in the park at one time, two being driven by ladies, one of whom was unattended.

A FEW weeks ago we mentioned that H.R.H. the Prince of Wales had ordered two additional 12-h.p. Daimlers for use at Sandringham. These, we now understand, have been delivered to Messrs. Hooper and Company, the well-known carriage builders, to be finished. In one of the cars the motor is under the seat, the body being built to carry sixteen passengers.

A MOTOR-CAR TOOL OUTFIT.

THE British and Colonial Motor Car Company, Limited, 14, Baker Street, London, W., are introducing a most useful motor-car tool outfit, the sole agency for which in the United Kingdom they have secured. The tools, which include everything likely to be wanted by a motorist, each have their allotted

place in a kind of "hold-all" provided with buckles and straps, so that the outfit when not required may be stored away in a corner of the car.

FURIOUS DRIVING CASES.

At the Hampshire Divisional Petty Sessions, at Kingsclere, on Friday last week, the Earl of Carnarvon, of Highclere Castle, was charged with having, on Sunday afternoon, the 16th ult., driven his motor-car at a greater speed than twelve miles an hour, contrary to the provisions of the Locomotives on Highways Act of 1896. Mr. T. W. Staplees Firth conducted the case for the defence. Lord Carnarvon did not appear. Superintendent Harry Wakeford stated that at a quarter-past three o'clock on the afternoon in question he was on duty in plain clothes with his bicycle, in the parish of East Woodhay, and saw Lord Carnarvon driving his motor-car from the direction of Highclere Castle towards Woolton Hill at a very fast rate. He followed the car on his bicycle, and was himself riding at the rate of twelve miles an hour, but the further he travelled the further he got in rear of the car. (Laughter.) He and a constable named Dann, stationed at East Woodhay, had timed the progress of the car over a mile of roadway between a certain bridge and Woolton Hill Rectory. They afterwards measured it, and found that the car was being driven at the rate of one mile in two and a-half minutes, or twenty-four miles per hour. The progress of the car caused a very big cloud of dust, which rose as high as the neighbouring trees, and the wheels of the car repeatedly skidded. In cross-examination the superintendent said he had previously received complaints from residents in the neighbourhood as to the excessive rate at which Lord Carnarvon drove his car. Police-constable Charles Dann confirmed the statement of the superintendent. He denied that they went there to trap Lord Carnarvon, but simply to detect him if he broke the law. The car went round the corner like lightning. For the defence Mr. Firth called a youth named Edward Trotman, who said he was mechanic in Lord Carnarvon's employ. He described his lordship as a very careful driver of motor-cars. Witness had travelled with him on his motor-cars about 6,000 miles. He accompanied him on the afternoon in question, but did not see any vehicles in the district. To the best of his opinion, the speed at which the car was travelling was under twelve miles per hour, and it would be impossible to turn corners at great speed. In cross-examination, Trotman said that on the afternoon in question Lord Carnarvon drove the car to Ogbourne in Wiltshire and back to Highclere. Mr. Firth contended that it was an un-English and unheard-of proceeding on the part of the police to go scouting about the country in plain clothes, as in this instance, for the purpose of trapping Lord Carnarvon. Apart from the police, not a single independent person had been called as a witness. The Justices having consulted a few moments without leaving the court, the chairman said they had no hesitation in stating that they considered that the charge made against Lord Carnarvon had been proved, and they had decided to inflict upon him the full penalty, £10, and costs. The Justices, he added, desired him to state that they considered that the police had acted very judiciously in the matter.

At the Long Melford Petty Sessions last week, Arthur R. Vickers, Lavenham, engineer, was summoned for driving a motor-car on the highway at a speed of more than 14 miles an hour on September 11th.

Defendant pleaded not guilty. Police-constable Pawsey, Lavenham, stated he was near the Common on the 11th ult., when he saw defendant driving a motor-car. Complaints having been received, witness timed defendant over a certain distance—from one telegraph post to another. The distance was 78 yards, and this was done in 80 seconds, the rate being 20 miles and a fraction an hour. Defendant declared the car could not be driven more than 14 miles an hour. Inspector Watling gave evidence as to last witness pointing out to him the spot where he stood and the telegraph posts. He corroborated Police-constable Pawsey as to the distance. Witness had cautioned defendant several times, complaints having been received of his furious driving. His pace was all right in the town, but where defendant was on the day in question was a regular playground for the children on leaving school. Superintendent Peake put in a note from one of the principal residents, complaining of the fast driving of the car, which was understood to belong to Mr. Brigstock, of Brent Eleigh Hall. Defendant repeated that the car would not go more than 14 miles an hour on an incline. The Bench decided to convict, the Chairman saying it was a pity more care was not taken by the drivers of these cars, which were dangerously driven. Fined 40s., with costs, 9s. 4d.

THERE was quite a group of Coventry motorists at Coleshill, on Wednesday, when John Budge, of Coventry, employed at the Humber Works, was summoned by the police for furiously driving a motor-car on the highway at Coleshill. Mr. Maddocks appeared for defendant. Police-constable Randle stated that the motor-car moved along at seventeen or eighteen miles an hour, and threw the dust up as high as the house. Mr. Maddocks denied that the motor-car was going at such a rate. He remarked that there was a good deal of prejudice still against motoring. Lord Norton said a person could not go a dozen miles an hour through a town. He might go at that rate along a country road, but a man who did so in the Strand would be sent to a lunatic asylum. Mr. Maddocks suggested that the man would not get as far as an asylum—he would be carried off on a stretcher. He called defendant, Councillor Snape, and Mr. Edward Yates, who were passengers on the motor, and they all denied that the speed was excessive. Mr. Maddocks told the Bench that the motor-car was outside the Court, and he invited them to inspect it, adding that it was painted with Mr. Murray's colours, and was found very useful in the Coventry election. The Chairman: What pace did it go at yesterday? Mr. Maddocks: Well, we went for 1,070 majority. (Laughter.) After the magistrates had consulted together, the Chairman said that there was no doubt that some motor-cars went too fast, but they did not think that there was sufficient evidence in this case to convict, and they therefore dismissed it.

ALLEGED OVERCROWDING OF A MOTOR-CAR.

At the Aberdare Police-court, last week, Frederick Evans was summoned for carrying a greater number than eight in a motor-car licensed to carry only eight. Police-constable Tompkins proved the offence, he stating that ten persons were on the car. Cross-examined: It was late in the evening. The defendant offered to show him his way bill, showing that there were only eight in the car. Mr. Kenshole, having addressed the Bench, called the defendant, who said that Pugh and Evans rode with him on the front. Witness produced his way bill, showing eight passengers on the car. The eight got up at Aberaman, and they went through without stopping. Cross-examined: He did not notice the police-constable until he came up from behind the car. Enoch David Perkins, the conductor, also swore that six got in at Aberaman, and no one entered the car after that. He saw the police-constable get up at that moment. There was a crush of people to get in before the rest got out. The driver asked him how many were in, and he said six inside and two outside. Cross-examined: He did not check the number on his bell punch with the driver. The Bench at this point dismissed the case.

TAKING a spin to the north of London the other day we found the water splash at Chalfont St. Peter absolutely dry.

AMONG repairers of motor-cars in the eastern counties the Anglian Cycle and Engineering Company, Limited, of Stowmarket, is becoming well known.

MR. MULLINER, of Northampton, and Messrs, Salmons and Sons, of Newport Pagnell, were responsible for the carriage work of the two motor-cars which ply for hire at Newport Pagnell.

SOME correspondence has been going on in a Nottingham paper on the manners of motorists. The failure of the driver of a motor car to stop when desired was the cause of the letters, the first of which was written by the Rev. A. Lockett Ford, evidently no great friend of automobilists.

At Milverton last week, Mr. W. G. Hammond, Earlsdon, Coventry, was fined 5s. and 10s. costs for driving a motor-car at Kenilworth after dark without a light. Mr. George Drury, of Coventry, was summoned for a similar offence, but on his application the hearing was adjourned until the next sitting of the court.

THE Motor-Car Journal.

VOL. II.]

LONDON, SATURDAY, OCTOBER 13, 1900.

[No. 84.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

PROBABLY one of the first cares of Lord Roberts on assuming command of the British Army will be to have a thorough investigation of the value of the automobile in military affairs. In South Africa he has seen the good work done by steam traction engines, and the recent experiments in connection with army manœuvres on the Continent have seriously impressed the officials of the War Office with the idea that automobilism may yet help the solution of the difficult problems in connection with transport. Anyhow the rumour to which we gave credence some time ago as to the early investigation of the subject has been revived, and something definite may be expected ere long.

Election Incidents.

DURING the last two or three weeks we have referred to several constituencies in which the motor-car has played its part in the General Election. To these should be added West Leeds, where a motor-wagonette carried batches of eight voters to the poll. At Hammersmith a passing motorist was hailed by some voters who wanted to be driven to the poll, and who seemed disgusted that no opportunity was given. Only one unpleasant incident in connection with the use of automobiles for election purposes has occurred. While Sir Mark Stewart, at the close of a meeting at Castle Douglas, was being driven to Kirkpatrick in a motor-car the vehicle was upset. The driver, in passing a wagonette, ran the car into the grass, and the ground being soft the motor-car plunged into a ditch and overturned. Captain Dunlop, who owned the car, got out and assisted Sir Mark to rise. In Mid Worcestershire Mr. Harmsworth's motor-cars were a perfect boon to him, the constituency being so widely scattered. His opponents laughed at them, but Mr. Harmsworth contented himself with the knowledge that he could cover an enormous quantity of ground with little or no trouble. In the Keighley division both candidates had the use of motor-cars. Motor-cars also played their part in the High Peak division of Derbyshire and in the North Norfolk constituency. Mr. L. Harmsworth found the motor-car very useful in his successful campaign in Caithness, on the result of which contest all automobilists will congratulate him.

Proud of the Speed!

MR. F. F. WELLINGTON sends us particulars of an amusing incident in which he was recently a party. Delivering a fast new car to one of his customers at a country town on the morning the poll was declared, he drove the new owner and his wife a distance of ten miles over very hilly roads, which were in bad condition from the rain, in about thirty minutes. Arriving at the Town Hall, where a cordon of twenty police were standing, the sergeant from the village from whence the party had ridden made kind and flattering remarks to the owners, and took a great interest in the new car, as did also his companions. The sergeant mildly inquired how long it took to accomplish

the journey. The lady, who was proud of her new car and its speed, at once replied, "Under the half-hour." Needless to say Mr. F. F. Wellington almost collapsed, and the police— The lady looked in wonder at them all until she remembered what she had done. No doubt the police for miles round will be on the look-out for this particular car, and Mr. Wellington fears that the road is blocked to him for some time to come.

Les Cloches de Corneville.

THE "Cloches de Corneville" have up to the present been nothing more than a name, for this Norman village, despite its stage fame in every quarter of the globe, has never yet boasted the possession of a peal of bells. The omission has been supplied by the Marquis de la Rochethoulon, whose efforts have been supported by other natives of Normandy. Funds were soon obtained sufficient to provide a carillon for this little township, and the inauguration ceremony on Sunday was made memorable by an open-air performance of "Les Cloches de Corneville," in the presence of 10,000 spectators. The interest to automobilists lies in the fact that the Marquis invited the members of the French Automobile Club to attend the fêtes, an invitation which was taken advantage of by a large number.

The Forthcoming Trials of Electrical Vehicles.

WE gave some particulars in our last issue of the forthcoming trials of electrical vehicles which are being organised by the Automobile Club. The trials will extend from November 5th to November 9th, and in addition to the tests already specified an additional optional trial for Friday, November 9th, is being arranged for, viz.:—A run over a given course for an unlimited distance on one charge, the driver to declare to the observer when the run is to be considered as finished. The same batteries will be used throughout, and during the course of the trials will be under the supervision of the Club. The energy consumed, number of passengers carried, average speed attained, will be recorded on certificates which will be granted by the Club to competitors, but no speed in excess of the legal limit of twelve miles per hour will be recorded or recognised. Competitors must supply drivers for their vehicles and must provide on each vehicle a seat for an official observer. The routes on which the trials will take place will be within fifty miles of London, but will not be made known to competitors until immediately before the trials. Competitors are required to fit to their vehicles reliable and accurate voltmeters and ammeters which can be read during the trials by the observers, and these meters must be fitted with terminals by means of which they may be tested by the judges.

English Motor Club.

THE next run of the English Motor Club will take place on Saturday, the 20th inst., and all particulars, including the destination, can be obtained on application to Mr. F. W. Bailly, 94, Oakfield Road, Anerley, S.E., or Mr. Charles Jarrott. Friends of members, as well as members of the club, are invited to participate in the event, and Mr. F. F. Wellington,

of St. George's Square, has offered to let members of the club have free stabling on the evening before the club run, so that country members coming up to town will not be inconvenienced.

Carnival at Chelsea.

CARNIVALS were plentiful in the summer, but have been fewer of late—many, including the great London pageant, being postponed till the return of the troops from South Africa. At Chelsea a very good carnival has just been held, the procession being organised on two evenings. Four motor-vehicles were in the procession, two Leyland vehicles belonging to the vestry being fitted up as an armoured train, a 5 h.p. Marshall car as the Demon Motor, and Mr. Frank Shepard's Daimler wagonette with the "Strolling Pierrots" in a trolley behind. The cars went well on the first day, but on the second evening misfortune seemed to dog their path. One of the Leyland vehicles broke a driving pinion, and the other ran out of water about half a mile from home. The Marshall car was also thirsty. At times there were over twenty persons on the trailer attached to the motor-wagonette. They gave an *al fresco* concert *en route*, and thus contributed materially to the success of the motor-car contingent.

Motor Tracks.

"A. B. C.'s" point raised in last week's correspondence in our columns has brought some replies this week and has been dealt with by some of our cycling contemporaries, one of which adds to our suggestion with regard to a motor track. It is suggested that "the track need not be formed in a complete enclosure, but should rather be arranged on the same principle as a railway, passing not only along the surface of the land, but through cuttings and over embankments, with slopes to go under or over public highways where necessary. The gradients requisite to pass under or over public highways would afford the vehicles the same undulating conditions as are experienced upon the highway; there would be no need to secure anything like a level surface throughout. The great cost of such a track has prevented its becoming an accomplished fact for cycle racing; but now that motor drivers are eager to experience the fierce wild joy of careering along at something over twelve miles an hour, it might be possible for the sinews of war to be forthcoming for the construction of such a track." Certainly the idea is not likely to be allowed to drop.

Nearly a Mile a Minute.

EXTRAORDINARY has been the speed attained by some of the leading automobilists, and at the recent Inter-Ocean tournament at Chicago many good performances were made. Steam vehicles were prominent in the various contests, and on his racing Locomobile Mr. T. E. Griffin went a mile around the track in 1 min. 6 sec. Seeing that the course was not a straight one, that its surface was rather loose, and that there was a good wind blowing at the time, Mr. Griffin will probably not be content until he has travelled a mile a minute on his Locomobile.

A Lengthy Trip.

THREE thousand kilomètres *en moto-cyclette* is a longish run, but such is the record of Mr. Orlovsky in making his recent trip from St. Petersburg to Paris. Coming to Paris to view the Exhibition, the tourist made no attempt at a racing performance, and took some fifteen days to make the journey. The route followed was by way of Louga, Pskow, Ostroff, Reijidsa, Dainsk, Kowno, Warsaw, Sloupszi, Posen, Schwerin, Kustrin, Berlin, Potsdam, Magdeburg, Braunsweig, Hanover, Minden, Hagen, Soingen, Bergheim, Cologne, Eupen, Verviers, Liège, Namur, Dinant, Givet, Rethel, Reims, Château-Thierry, Meaux, Lagny, and Vincennes. We believe Mr. Orlovsky had previously made at least one unsuccessful attempt upon the same voyage, bad roads and weather causing failure. But upon this last trip the Russian cyclist was favoured with glorious

weather, and he found the roads not very bad. Certainly, to make a journey of this length, fine weather, good roads, and absence of *pannes* are essential features, if any pleasure and comfort is to be secured. The train takes Mr. Orlovsky back to his fatherland, not that he fears the return journey *en auto*, but because time forbids.

A Queer Case at Swansea.

WITH reference to the alleged furious driving case against Mr. Arthur W. Heard, of the Century Engineering and Motor Company, Limited, Altrincham, reported in our issue of the 29th ult., we have been favoured with some correspondence which illustrates the uncertainty and, we might also add, the absurdity of the law. The case was heard at Swansea on the 19th ult., but the first intimation that the defendant had of the proceedings was a telegram from a cousin at Swansea (on the 18th) who had given a local solicitor the facts of the case on that day. Mr. Heard wrote at once giving the solicitor a full answer to the charge, but that letter did not reach him until the case had been disposed of. We cannot understand why Mr. Heard had had no official intimation of the summons, and why he was thus placed in an absolutely defenceless position. Surely this is not in accordance with the spirit of the English law.

Le Poids Lourds.

MONDAY last witnessed the commencement of the annual competition for heavy automobile vehicles, known as "Les Poids Lourds," and to-day will see its completion. The vehicles are required to follow two itineraries in the neighbourhood of Vincennes, the total mileage for the five days' work being some 157 miles. The object of the competition is to promote the industry in relation to public transport work, transport of merchandise and delivery services. The automobiles permitted to compete are—(1) Vehicles carrying at least ten passengers, independent of the driver, with thirty kilogrammes of baggage; (2) goods vehicles carrying at least one ton under the same conditions; (3) delivery vehicles transporting a load of at least 1,250 kilogrammes. Not only are the cars required to make their two journeys daily, but they are put to various tests on ascents and descents, on macadam and *paré*, to ascertain their facility of manœuvre. We hope to give some details of these interesting experiments in next week's issue.

"Motor-Car Smash."

A TYPICAL instance of what the general newspaper calls a "motor-car smash" is reported elsewhere in our columns as having occurred at Eastbourne. The examination at the inquest, which had, unfortunately, to be held in connection with the death of a lady thrown from a trap, revealed several facts which demonstrated very clearly that automobilism was not the cause of the accident, and the foreman of the jury was unprejudiced enough to make that point very clear. More than that, the jury endorsed his view, and placed the fact on record. Probably a few such cases would enlighten the public, and cause them to realise that motor-cars are not the cause of every mishap that occurs on the road.

Reckless Driving in Paris.

IF a repetition occurs of that reign of terror which followed upon the accident at Croix des Noailles in the spring, Parisian automobilists will have only themselves to blame, for many of them really appear to be utterly regardless of life and limb. Just as, in the cycling world, it is but very seldom that the better class of rider gives cause for complaint, so, in the case of automobiles, it is not the gentleman driver who "scorches" to the terror of pedestrians, but usually it is the young engineer or employé of an automobile firm, who makes a nuisance and a danger of himself with property which does not belong to him. But a cloud is again looming up, for as the result of a recent accident in the Avenue de Clichy, and the

subsequent flight of the author, Monsieur Edmond Lepelletier, the municipal councillor of the Batignolles district of Paris, has inscribed upon the agenda of the Council's first meeting after the vacation a question which he purposes to ask Monsieur Lepine, the Préfet of Police. Monsieur Lepelletier wishes to ascertain whether any preventive or repressive measures are taken to prevent the authors of automobile accidents from evading their penal and financial responsibilities. Only too frequently does one read in the Parisian papers that after knocking somebody down, or causing some sort of damage, the *chauffeur* took to flight, and little hope is entertained that he will be found. The most regrettable feature from an automobilist's point of view is that all must suffer for the errors of the few; but that is inevitable, as, of course, distinctions are obviously impossible. It is possible, too, that this action by M. Lepelletier will have a direct bearing upon the decision of the Préfet of Police and the Committee of Traffic, who are about to discuss the question of numbering all self-propelled vehicles. It will undoubtedly come to the marking of cars and cycles sooner or later, so automobilists may prepare themselves for the worst. Let us hope that the numbers will be smaller than those used in Belgium.

Motor Dust Vans.

EDINBURGH is so essentially a city of light and leading that no surprise will be felt at the suggestion that motor dust vans will be found in its thoroughfares ere long. Several members of the Town Council are reported to have declared in favour of such an innovation, and when their wish is gratified there will be plenty of experience with regard to motor dust vans to guide other municipalities that may be wishful to develop their municipal work to give the best results to the townspeople.

Heavy Motor Vehicles and Traction-Engine Builders.

"OBSERVER," in his Heavy Motor Notes in the *Liverpool Journal of Commerce*, draws attention to the apparent lack of interest exhibited by traction-engine builders regarding the Locomotives on Highway Act, 1896, under which motor-wagons live, move, and have their being. The reasons why the new field has been left to enterprising firms previously engaged in other branches of engineering are, considers "Observer," two in number. First, that there has been a very large business doing in traction engines for agriculture, export, and, recently, the war. Second, that tradition, custom, practice, or what you will, has made great weight part of the traction-engine builder's creed. These two factors have caused the construction of not a few promising vehicles to be abandoned for work of more immediate urgency and profit. Traction-engine builders, as a body, are, however, slowly beginning to realise that newcomers are finding a lucrative trade in the lighter types of road engine, that they are not, after all, the only wise people in the world, and that there is, notwithstanding their pessimistic prognostications, a demand for the motor wagon. One firm, at least, Messrs. Charles Burrell and Sons, Limited, of Thetford, Norfolk, who have had the question before them for several years, but have been unable to prosecute its solution through pressure of their standard work, intend to enter a vehicle in the 1901 heavy motor vehicle trials in Liverpool.

A Grease Story.

A BAD skid on a dangerous road is one of the ugliest experiences a motorist can have next to a downright accident. The writer recollects on one occasion when out with a well-known driver coming suddenly on an S-shaped curve with a good incline. The road was very narrow, and bordered by a gripe at each side fully 10 ft. deep. There being no expectation of mud we came to the corner too rapidly. The steersman not daring to touch his brakes slipped his gear, and braced himself over the steering wheel. It was a heavy car; we were four passengers, and there was no room on the road for playing about.

Straight through we glided for a bit. Then came a lurch, such as a boat gives in a choppy sea, and the car took a horrible slew towards the left ditch. It was a horrible sensation, this slithering. The driver let her slide till we were on the brink of the ditch, and then with a strong sharp swing of the wheel fetched her head in the opposite direction. We still had considerable way on, the road was downhill, and nothing short of grappels could grip in the slippery syrup under the wheels. Saved from one ditch, we rapidly glided towards the other. Again the driver coaxed her from destruction, and away again in a terrible zig-zag we slewed. It all lasted only a few seconds till we righted and held the middle of the road again, but it seemed painfully long. The second curve had nearly been our undoing, for at the critical moment, and judging all to be lost, the box seat passenger flung himself on the wheel in a wild desire to cling on to the steersman. It took fine skill and pluck for the driver to avert disaster, but by his judgment and coolness he nursed the car out of the zig-zags and got her fair again. And then he talked to that passenger!

Some New Voiturettes.

SEVERAL new types of voiturettes, of which we hope to say more anon, have lately been seen flitting about Holborn Viaduct. One is an exceedingly neat production by Messrs. Darracq, of Paris. It is built low, and is provided with the increasingly popular *tonneau* type of body, there being accommodation for four persons. Another light car of French construc-

tion which we saw on Wednesday is the Bardon, of which an illustration is given herewith. This car, a description of which was published in our issue of January 19th last, is fitted with a 4 h.p. motor of novel construction. The engine comprises one cylinder, there being, however, two pistons with a central explosion chamber. Judging from our brief view of the car in operation it appears to run very smoothly.

Repairing Firms.

WE have received several intimations from engineers and others with regard to the appointments of repairers now being made by the Automobile Club, and also by several leading firms. At present, however, no complete lists are available, and hence the publication of these names is being withheld till official notification is given of the appointments. This seems the fairest way of dealing with matters, the negotiations in connection with which have not been wholly concluded.

Motor-Cars for Medical Men.

MR. C. T. W. HIRSCH, M.R.C.S. Eng., L.R.C.P. Lond., Woolwich, has sent the *Lancet* an account of his experiences with a motor-car, from which we extract the following:—"The car I invested in was a Benz Ideal No. 2, with a hood An instructor was left for a week at the charge of 7s. 6d. a day plus his railway fare and meals. I am afraid I did not derive much benefit from him, and when I started driving myself I must confess I had a great deal of trouble, the car frequently stopping

in the street, due to my not managing the mixture properly. When this was mastered and the regulation of the coil's vibrator seen to, the car went splendidly, and in addition to my doing my work in this hilly district I have had some three trips to the south coast watering places, as well as many daily excursions of from 40 to 60 miles. The machinery on the whole is good. One of the carriage springs broke. . . . A fresh one was supplied, but a charge was made for the labour, the firm from whom I purchased the car supplying a new spring gratuitously. The tire on one wheel became loose, due to the wire breaking. This was also mended gratuitously, though the agent charged for the time he spent and the expenses incurred in taking the wheel to the maker's. The only other trouble of import was that the bush on the second speed loose pulley became worn, and as a result the pulley was not quite true and occasionally gripped the true pulley, and when driving on another speed a loud noise, violent vibration, and pulling up of the machine occurred. The wearing of the bush was said to be my own fault, as though I kept the grease-box well filled the hole in the lower part must in some way have been blocked. . . . I have heard that a car has run 35,000 miles without requiring attention. I am afraid I cannot say the same for mine. Motor-cars certainly are very useful, but liable to get out of order, and I question whether I would buy one again with my present experience. . . . We hope Dr. Hirsch will recover his spirits, and not continue long in the saddened frame of mind in which he evidently is at present. There is certainly no reason for discouragement. His first failures arose from neglect in managing the mixture properly, and he should have watched the wearing of the bush more closely than he seems to have done. These little omissions he does not deny, while he testifies to the quality of the machinery and the splendid runs he has had on the car. Why he should have written those last few lines we do not know.

An Automobile Meeting at Chicago.

THE first International Automobile Exhibition and Tournament was held in Washington Park, Chicago, towards the end of September. The exhibition may be considered a success from the standpoint of the builders, as they report many sales at the grounds. However, very little was shown which was new in principle, only the familiar types being exhibited. The principal exhibitors were: the Woods Motor Vehicle Company (electric), the Mobile Company of America (steam), the Chicago Motor Vehicle Company (petrol), the American Bicycle Company, several types of electric vehicles, a petrol car and tricycles, the Hewitt Lindstrom Company (electric), the Locomobile Company of America (steam), the St. Louis Motor Carriage Company (petrol), the Ohio Automobile Company (petrol), the Milwaukee Automobile Company (steam), the De Dion-Bouton Company (petrol), the Olds Motor Works (electric), and the Eastman Automobile Company. Chief interest was, however, centred on the attractive programme of races that had been drawn up. On Thursday, the 20th ult., in a 15-mile flying start motor-tricycle race, Champion beat Skinner, the time being 24 min. 47 $\frac{3}{4}$ sec. In the ten-mile race on the 21st ult. our old friend C. G. Wridgway came out successful, covering the distance in 15 min. 19 $\frac{1}{2}$ sec., as against 15 min. 48 $\frac{3}{4}$ sec. by Skinner, and 15 min. 55 sec. by Champion. On Tuesday, September 25th, Champion, however, beat Wridgway in a five-mile race, and afterwards covered an exhibition mile in 1 min. 19 $\frac{1}{2}$ sec. The racing events were, as a rule, not closely contested on account of the lack of racing machines in the United States at the present time. The motor-tricycle races seemed most interesting to the spectators on account of the sustained speed of the machines and the able manner in which they were handled by their riders. One of the most exciting events was the 50 mile race for motor-tricycles, in which Champion, riding a machine fitted with two Aster motors, snatched victory from defeat, when Skinner, after reeling off over 40 miles with that regularity of action which has made the De Dion motors famous among the air-cooled types, and leading the Frenchman by half a mile, was

unfortunately put out of the race by the setting of the inlet valve of his motor. Skinner used one of the large-sized cylinders, developing about 3 $\frac{1}{2}$ h.p., while Champion's two cylinders are rated at 6 h.p. Wridgway, the third entry in these races, had a 2 $\frac{1}{2}$ h.p. motor, and consequently was hopelessly handicapped.

MOTOR BICYCLING.

MR. JOSEPH PENNELL'S enthusiasm for motor-bicycling finds further expression in a second article in the *Daily Chronicle* on Friday last week, in the course of which he gives some interesting conclusions, and attempts some prophecies as follows:—

"I have driven my motor-bicycle at the rate of four or five miles an hour through Piccadilly, Pall Mall, Hyde Park Corner, and Charing Cross on a busy afternoon, with a feeling of greater security than on an ordinary safety, because I could put my feet on the ground. The bicycle parts, though extremely strong, are not of the best quality and finish, and the pedals and cranks are far too near the ground. Several times I have hit stones. But all motor-bicycles should be built like the Werner, so low that the driver can put his feet on the ground in case of an emergency. The rider of a motor-bicycle must also be a good rider of a cycle. The power to steer, to keep one's head when driving at a high rate of speed, to avoid obstructions in the road, will only come naturally to a good cyclist. On the other hand, there is some disadvantage because the experienced cyclist tries to put on the brake and back-pedal, instead of switching off the electric current. But, whatever your training as cyclist, you must understand these motors, while endless patience is required to drive them. Once you have mastered the details, however, the fascination of driving this almost human thing is intense, and a few week's practice should enable anyone to do what I have done and to make longer journeys. On other forms of motors I have been troubled by vibration owing to the motor being behind or under me. On this machine I have experienced nothing of the sort. The only physical drawback is the number of burns, blisters, scratches, and bruises on my hands, from which, like any other person who works with machinery, I seem to suffer. If you are willing to study the motor-bicycle I see absolutely no reason why you should not learn to drive it. But it is a very different thing from riding an ordinary safety. Within three or four years I am certain that some sort of motor will be affixed to every bicycle, if only to be used up-hill, against the wind, and when the rider is tired. I am perfectly prepared, however, to find the makers of all motor-cars, tricycles, and quadricycles in opposition to me. But then, scarcely any of the owners of these machines have driven a motor-bicycle, and, as for the makers—well, a 3 h.p. voiturette may cost two hundred pounds, while a 2 $\frac{1}{2}$ h.p. bicycle, which is now being made in England, may cost fifty; but this, of course, has nothing to do with the prejudice of the manufacturers of motor-cars against motor-bicycles. The motor-bicycle is as sure of setting the fashion as the Rover safety was, and it will add as much to the pleasure and comfort of the world as the development of the safety and the pneumatic tire."

THE city council of Dayton, O., U.S.A., is wrestling with the automobile problem, and an ordinance regulating the speed of such vehicles to eight miles an hour has been introduced. The ordinance also provides that these vehicles shall be equipped with lamps and bells, and requires the operator to stop his vehicle as soon as he discovers that a horse is frightened by it.

THE City engineer of Chicago, Ill., who is a member of the examining board for automobiles, declares that he has heard of so many cases of lady operators without licences that he intends to ask the authorities to order his officers to arrest all the lady automobilists who have not the necessary badge. Many of the leading society women are said to be included in the number who have not passed the requisite examination. So far only eight ladies have secured permits to operate electric vehicles, but it has been discovered that there are twenty-five to fifty ladies regularly running the machines through the city.

The Automobile Club's Autumn Tour.

MONMOUTH -FROM THE RIVER.

IN dreary weather those members of the Automobile Club who had intended to go to Monmouth for the autumnal tour assembled outside the club house in Whitehall Court on Friday last week. They gathered in silence, and very lugubrious were the salutations exchanged, for the clouds loomed threateningly darksome and there was a sense of coming dampness in the air. Of the dozen likely starters most were early at the rendezvous, and a few passers-by stopped to gaze upon the enthusiastic motorists who were prepared to dare rain and wind for the enjoyment that comes from travelling without horses. Mr. F. H. Butler, on his white Panhard, was among the early arrivals. With him Mr. Morgan was a passenger. Mr. Jarrott drove up with Mr. Napier on a De Dion

hovered ominously overhead. At Hounslow we saw Mr. Colès on his new voiturette, and a Bollée by the roadside, the latter evidently being in process of repair. A little further along a Benz car came from the opposite direction plentifully bedecked with mud.

The road was naturally heavy and thick with mud, but despite that good progress was made to Slough, where we halted about ten minutes to await the arrival of any other cars that might be immediately in our wake. None coming the run was resumed. A little later Mr. Bird's 12-h.p. Panhard was seen, Mr. Bird, jun., driving, with his father by his side, and Mrs. and Miss Bird in the *tonneau* seats. They literally flew past us, and their flight struck us as very

[Mr. C. Crompton.]

A HALT ON THE WAY TO TINTERN.

voiturette, and Mr. Friswell's beautiful 12-h.p. Panhard was a notable contribution to the display. Mr. Johnson was busy marshalling the starters when Mr. C. Cordingley appeared on his Marlborough phaeton. Mr. Staplee Firth and Mr. Freeston were among the members assembled to bid farewell, and then, punctually at 2.30 p.m., a start was made up the Horse Guards Avenue into Whitehall.

We had gone but a short way when the rain came down. There was no mistaking its intentions, and it was evidently in a tenacious mood. Passing a cream-coloured Panhard in Hyde Park, we continued our journey (with the rain stinging our faces) through Kensington and Hammersmith to Hounslow, where the storm seemed inclined to abate somewhat, although heavy clouds

appropriate. Very variable was the condition of the roads—at times slippery and at others dry and hard. Occasionally the sun, looking watery and modestly temperate, essayed to shine, and at six o'clock we reached Wallingford without incident and with no side-slips. Waiting at Wallingford we were joined three-quarters of an hour late by Mr. Loeffler on his 6-h.p. Panhard, with Mr. Martineau also aboard. They reported that Mr. Butler had put up on the way till the rain ceased.

About Henley there were signs of the South Oxfordshire election, but of excitement there was none—the voters as well as the roads having been dampened very considerably. For a distance of about two miles the roads were white with pamphlets, handbills, and posters advocating the merits of Mr. Herbert

Samuel, who had evidently made great use of printer's ink in his contest. Several wagonettes were seen on the road two and three miles from anywhere. Disconsolate indeed were the drivers, and never a voter did we see them convey to the polling

THE MONNOW BRIDGE, MONMOUTH.

stations. At the booths themselves there was little sign of life, certainly none of vigour.

It should be mentioned that on the road to Henley there were a few stiff hills to be negotiated, and after leaving the famous riverside town—what a dismantling of the brightness and glory of the Regatta week does Henley present in the autumn!—there were two other steep hills, making very heavy going. Despite their gradients our good car mounted them boldly, and we journeyed on in comfort and with satisfaction. From Nettlebed to Wallingford—a distance of six miles—the way was practically all down hill.

Shortly before seven Mr. Mark Mayhew joined us on his Renault voiturette with a hue ruddily reminiscent of the car that the Hon. C. S. Rolls once exercised around the grounds of the Crystal Palace to the consternation of the old gardeners there. Mr. Johnson came in on an Orient Express about eight o'clock, and a couple of hours later Mr. Butler appeared. The next arrival was Mr. Reynolds, with Mr. Claud Crompton as passenger, on a Peugeot voiturette purchased from Mr. Rolls a few days before. Neither of the young fellows knew much about the car, and it had not grown accustomed to their ways. Hence the fact that they had been between seven and eight hours on the road was not surprising. Although the clock had struck ten, motorists continued to arrive, the late ones including the Rev. A. Whatton, who had a lady passenger on his Canello-Durkopp car. He had started late from town. Mr. Lyons Sampson drove Mr. M. Bruce, and

Mr. Sturmey came by train from Coventry. These were the last to appear at the George Hotel on Friday, and the thanks of the party of fourteen motorists are due to the landlord and landlady for the way in which they attended to their wants. Mr. Loeffler

Photo by (Mr. C. Crompton.)

and his friend returned to London the same evening; the others slept at Wallingford.

The morning of Saturday was in strong and pleasant contrast to that of the previous day. Blue skies and a bright sun gave spirits to the party, and, breakfast over, preparations were made for an early start on the second stage of our trip to Wales—

no, Monmouth. Mr. Allen, with a lady, came over from Oxford on a new Daimler car and accompanied the party to Cirencester, from whence he returned to the University town. Accommodating Mr. Johnson, the Club secretary, with a seat on our own car, we started off in the face of a stiff head wind. Between breakfast and the start the aspect of things had changed, and gathering clouds threatened to dispel the promise of the early morning. We got away from Wallingford just before half-past nine, but unfortunately took the wrong road, and found ourselves

TINTERN ABBEY.

in a lane overgrown with grass. However, we managed to get to the main road again, when, alas! one of the burners began giving us trouble, a state of things made familiar enough on the 1,000-mile Trial. A halt was made at Wantage to put in a new burner and examine the statue of King Alfred, who is reputed to have first seen the light in that interesting old town. The Bear Inn is a quaint place well worth a visit, the bear on a pedestal in front of the hotel being somewhat unique in signs. Here, while we were waiting,

Mr. Bird passed. Then we continue our journey *via* Faringdon, St. John's Bridge—where the Trout Inn is—over the Thames, here clear and silvery; so narrow and so different from the Thames of the lower reaches—the river shimmering in the half reluctant sun, and the well-stocked waters filled with leaping fish—through Lechford, past Fairford, where is to be seen an interesting old church with a beautiful stained window which, to save it from the ruthless hands of the Parliamentarians, was buried many feet beneath the earth, afterwards being reverently restored by the

THE ENTRANCE GATE—RAGLAN CASTLE.

loving hands of the descendants of those who had so carefully preserved the beautiful treasure. And so on to Cirencester, which was reached just before one o'clock—a minute or two after Mr. Allen's arrival, he having passed us while we were attending to our pressure valve, water having collected from the bad petrol, which gave us considerable trouble all through the day. Mr. Butler, whom we had noticed behind us for some distance, followed us in; Mr. Mayhew arriving solitary, but happy, at 1.10 p.m. The horses along the route had been extremely troublesome, and many stoppages had to be made. The wind in our faces was terrific and rain kept threatening, but fortunately the clouds were dodged, and so we escaped. One horse slipped into a ditch, quietly lying there nibbling the grass around, while in another instance a cartload of apples—evidently for cider purposes—came to grief. Excitement was caused just before lunch by the arrival of Mr. and Mrs. Edge on their 16-h.p. Napier, having ridden down from London. They started at eight o'clock in the morning, but had mistaken the road. Mr. and Mrs. Hargreaves arrived on their 12-h.p. Daimler at 1.30, and Mr. Sampson at 1.45.

After lunch a fresh start was made, and we had proceeded about six miles when Mr. Bird passed, being closely followed by Mr. Hargreaves. The road was a continual rise, and some of the ascents were very steep, the roads also being greasy and consequently slippery. The top of Birdlip Hill, about which many tales had been told, was duly reached, a C.T.C. board acting as a warning. The commencement of the decline is not only precipitous, but the surface consists chiefly of a series of watercourses. Brakes were closely applied, and it was soon seen that Birdlip was no common hill. We proceeded as slowly as circumstances permitted, but the hill was somewhat circuitous and there was a lot of traffic about. Squeaking along, we were suddenly assailed with a loud shout and saw Mr. Edge coming slowly down, enwreathed in a cloud of blue smoke. We drew aside and Mr. Edge came up, informing us in return for our salutation that our hand brake was also on fire. We continued down for another couple of miles, and then both obtained water with which to cool the brakes from a cottage. Down hill, it seemed, all the way into Gloucester. The roads were greasy, and in the town the tram lines were especially bad. From Gloucester to Monmouth, through Ross, was a very pretty ride, overhanging fruit trees forming arches

across the road, while bushels of apples and pears were lying all over the roads, being scrunched by hundreds beneath the wheels of the various cars. A stoppage was caused in crossing the Wye at Kerne, where a charge of sixpence was made, and then shortly afterwards Mr. Rolls dashed by from the opposite direction on his Panhard. On Whitechurch Hill, a short, sharp, and steep ascent, Mr. Mayhew came up and passed us, and then, after surmounting the summit, a greasy surfaced decline took us at a sharp pace straight to the Beaufort Arms, the distance for the day having been 85½ miles. The clock had struck six five minutes before, and we had followed Mr. Mayhew within a minute of his arrival. Here was met Mr. Holder, who had ridden over from Birmingham on his 12-h.p. Daimler. We also heard that Mr. and Mrs. Kennard had passed through to The Hendre, Lord Llangattock's place, some time before, after having side-slipped and bumped another vehicle. We also learnt that Mr. Hargreaves, in descending Whitechurch Hill, had turned completely round on the greasy road.

Messrs. Butler and Sturmeay arrived at seven o'clock, and the first words said were, "Did your hand-brake fire?" Theirs had burnt to pieces and a new one had to be affixed. Mr. Johnson was considerably exercised as to the fate of the remaining cars and wired to the post office at the top of Birdlip Hill to endeavour to find out whether anything had happened. The reply was that nine cars had passed. Other vehicles came along, including Mr. Sampson's, with hand-brake broken, but at bedtime two cars were still missing, Mr. Whatton's and Mr. Reynold's. From Mr. Burgess, who had started that morning from town on an English Panhard, a "wire" was received shortly after seven with the Gloucester post mark stating that he and his party were staying in that town for the night and were coming on in the morning.

Although the distance for the day was only eighty-five miles we are inclined to think the ride was one of the most difficult yet undertaken by the Club, and that it equalled, if not surpassed, any of the day's rides on the 1,000-mile Tour. Birdlip Hill certainly was one of the worst we have yet negotiated, and although the contour book gives a portion of the gradient as one in seven, we are inclined to think at points the gradients were much steeper. Such a number of hand-brakes burning and a car to

THE MEMBERS ARRIVING AT THE HENRE, MONMOUTH.

run away and then turn over formed a record in the annals of the Automobile Club tours.

Sunday was a lovely day, warm and bright, and the interesting little town of Monmouth, in which Henry V. was born, looked its best. According to our programme, the day was one of rest, and so the various members made their own arrangements to spend the day. Some went to Ross and some to Tintern, while a party of four, consisting of Messrs. Butler, Cordingley, Johnson, and Sturmeay, set off for a five-mile walk to Symonds Yat. Walking up

Whitchurch Hill, we met Mr. Burgess coming in from Gloucester, with five passengers up—including Mr. Freeston, Mr. Willoughby, Mr. Crompton, and Mr. Reynolds. These two latter were the gentlemen who came to grief on Birdlip Hill on a Peugeot. It appeared that the first part of the hill was ridden with safety, until when turning the corner of what looks like a level portion of the road at the bottom of the hill, the hand-brake broke and the car shot like an arrow from the bow. Another turn was seen in front and the car was then swaying all over the road, being beyond control. Mr. Crompton jumped just as the

and here found Messrs. Bird and Edge with their cars. Some lunched on one side of the river and others ferried across. We were with the latter, and had lunch at the Rockleigh Hotel, a prettily situated inn, with beautiful views of the Wye Valley. After allowing due time for digestion we pedestrians varied the monotony of the outward journey by taking a boat back. The river was in flood, and rushing along at about four miles an hour a most enjoyable row was indulged in.

Several members of the party were sleeping at The Hendre, and on Sunday afternoon frequent visits were passing between

A GROUP AT THE HENDRE, MONMOUTH, INCLUDING LORD AND LADY LLANGATTOCK, LORD BRASSEY, AND SOME WELL-KNOWN MEMBERS OF THE AUTOMOBILE CLUB.

[Photo by]

[J. H. Preston, Monmouth.]

car completely turned over, with Mr. Reynolds at the helm. He was buried underneath for a moment and then the car continued on its way, turning over several times, at last righting itself and so remaining. The young fellows were soon on their feet, and they rushed to turn off the petrol tap, when both burst into laughter, for the petrol tank was lying about forty feet away in the road. Fortunately neither of the riders was much injured, Mr. Reynolds being cut a good deal, and Mr. Crompton escaping with bruises and torn clothes. The body of the car was entirely wrecked and the back axle bent. Fortunately Mr. Whatton came up and towed them into

the two detachments. Mr. Hargreaves drove in with Lord Brassey, and Mr. Edge drove his lordship back again.

Monday, like Sunday, was beautifully fine and mild, and the sun shining benevolently rendered overcoats unnecessary. The morning was spent by many of us at Tintern Abbey, but the ruins to those who had seen Glastonbury, Melrose, and other places did not seem worth the twelve mile drive, although the scenery all along the valley of the Wye was most beautiful. Returning to Monmouth, we made our way to the Hendre, where photographing was in active progress by most of those assembled. The day was like one of spring, and all the time was spent in

THE PARTY LEAVING THE HENDRE, MONMOUTH.

[Photo by]

[J. H. Preston, Monmouth.]

Gloucester, where Mr. Burgess saw them as he was riding through with the intention of coming on to Monmouth. However, not knowing whether there were any more Birdlip Hills on the way, he thought discretion the better part of valour and made up his mind to stay with the others in Gloucester. All this we heard on the hill, and as Mr. Burgess's car continued its way down we resumed our march up the hill, stopping to examine with interest the outward and visible signs of Mr. Hargreaves's side-slip. The "slips" looked very nasty, especially the one making the deep indentations in the bank. All walks come to an end in time, and after a 150 minutes' toil, we reached the Yat Hotel

the open air. A *recherche* luncheon was served in a covered tennis-court, and after due justice had been done to the good things prepared, Mr. Butler, the hon. treasurer of the Club, proposed the health of Lord Llangatock, who warmly replied, expressing thanks for the hospitality shown by the various members of the club to his son, the Hon. C. S. Rolls, of whom he was so proud. After luncheon the cars were crowded to their fullest capacity, many sitting on the floorboards, to take the party to Raglan Castle, where the magnificent ruins, covering over five acres, attracted attention for nearly two hours. Lord Llangatock

personally conducted the party and headed the visitors' book with his own name, followed by Lord Brassey, who formed a scroll and inscribed the fact that the signatories were members of the Automobile Club. These tours, there is no doubt, do much good to the industry, and on Sunday we heard that Dr. Lloyd Smith, a leading physician of Monmouth, had taken a great fancy to a phaeton driven by Mr. Burgess, of the Motor Manufacturing Company. After testing the car he placed an order for one to be delivered in about six weeks' time. We also understand Lord Brassey has ordered a voiturette. All the cars were running well, except Mr. Kennard's Napier, which was seen at the side of the road, and on our return journey we had the pleasure of staying a few minutes and talking to the owner of "Sir Charles." His troubles were concerned with tires, and he informed us that the present was the third tire that had gone in three days, and he had only been riding to a little extent. He has on the car a patent pump and bell that rings when the tire is deflated. We stayed to hear the bell ring, but the tire was on the ground, and the car went on but the bell did not ring. An item of news to our readers is the fact the *mecanicien* was hard at work pumping the tire by hand. Tuesday was also a lovely day with a little wind and a little briskness in the air, but as the sun got up it was really springlike. The journey for the day, according to the "Notes and Notices," was 86½ miles, but an error has been made, and the journey was only 68 miles. Luncheon should have been partaken of at Gloucester, but as that cathedral city was only 26 miles distant, it was decided to take the mid-day meal at the "Queen's," Cheltenham. We stayed at the Bell Hotel to have a look at the wreckage of Mr. Reynold's Peugeot, and afterwards came through, arriving at Cheltenham just before noon. A start was made again at three, and we rode over the Cotswold Hills, where the Thames narrowed to a ditch-like extent. We passed through country in which the motor-car is evidently a comparative stranger, and through Witney, over a bridge crossing the Thames at Eynsham, where a toll of 4d. was charged. Frequently we had to slow up to avoid pheasants feeding in the road. Oxford was reached in ample time for seven o'clock dinner. Here the members, whose numbers had been very much reduced, were entertained by Mr. Allen, who resides close to the city. On the last day's ride the morning opened dull, but it brightened later. An early start was made for Iffley, where is one of the finest examples of a Norman church to be seen in this fair land of ours. After examining the architectural beauties a journey was made to Mr. Allen's beautifully situated house, overlooking the Thames, and then a move was made, Mr. Allen leading the way, his wife driving his Daimler to High Wycombe, and the club-house was reached by the first of the cars just before four o'clock.

THE tour in Tunis, which is being organised by the French Automobile Club, has been postponed until March next.

THAT well-known Belgian automobilist, Baron de Crawhez, is contemplating a tour in Algeria on his 12 h.p. car early in December.

THE United Motor Industries, at whose invitation "Lollius" made the trip on a Clement Panhard voiturette referred to last week, have issued a neat little booklet giving a list of their agencies and leading lines.

SEVERAL interesting photos of the visit of the members of the Automobile Club to The Hendre, Monmouth, on Monday last, were taken by Mr. J. H. Preston, of the Wye Valley Studio, Monmouth, from whom copies can be obtained.

WE learn that four 50-h.p. Napiers are being put on the stocks—not three, as mentioned in our last issue. They are to be built to the order of Lord Carnarvon, Count Zborowski, Mr. Mark Mahew, and the Hon. C. S. Rolls respectively.

THE *Breslauer Generalanzeiger* states that while Prince von Pless was travelling by motor-car from Fürstenstein to Schweidnitz, accompanied by Princess von Pless and two English friends, a horse ran against the car and overturned it. All the members of the party were more or less injured on the face and hands with broken glass.

THE LUFBERY MOTOR-CAR.

A MOTOR-CAR exhibited at the Paris Exhibition which comprises several novel features is that built by Charles E. Lufbery, of Chauny (Aisne), France, and of which illustrations are given herewith. The car takes the form of a four-seated phaeton, with a hood to the rear seats. Originally Mr. Lufbery used the Daimler motor, but he has now perfected a motor of his own design—a twin cylinder, vertical engine, with a bore of 92mm. and a stroke of 146mm., which, at its normal speed of 700 revolutions per minute, develops 6 h.p. The engine, which, complete, weighs 300lbs., is bolted down to the tubular frame of the vehicle, and is located in the rear. The cylinders are water-jacketed, the circulation being maintained by means of a pump. The new feature is, however, not so much the motor as the

FIG. 1. -PLAN OF FRAME OF LUFBERY CAR.

variable speed-gear adopted, which is arranged to give no less than five speeds forward and three in a backward direction. An extension of the engine shaft carries a cone pulley with three steps, and power is transmitted from this to a similar cone pulley, on an intermediate or differential shaft, by a single belt. From this shaft the power is conveyed to the rear road wheels by the usual duplicate set of sprocket wheels and chains. In the interior of the pulley on the intermediate shaft is a mechanism by means of which this shaft is made to rotate at half the velocity of the pulley for forward motion, and by which the vehicle is reversed. The intermediate shaft, with pulley, etc., is shown specially in Fig. 3. To the cone pulley are fastened, interiorly, two gears, one spur-pinion 3, and one internal gear 2. Both of these are made of phosphor bronze. On the hollow shaft is mounted a double-armed piece 5, which may slide along the shaft on a long

feather key. At the end of each of these arms there is a bearing, in which turn the double pinions 4, 4, which are of steel cut from the solid. The smaller one of the pinions 4 engages with a pinion keyed to the hub of the drum 6. On the drum 6 acts a brake band, not shown in the figure.

After this explanation the operation of the device may be easily understood. Let us suppose the large pinion 4 to be in gear with the internal gear wheel 2, and the two members of the friction clutch to be slightly separated by means of the shifting lever 7, operated by a hand lever placed convenient to the operator. The brake band on the drum 6 is drawn tight, to prevent the drum from turning. The rotation of the pulley 1, and consequently of the gear wheel 2, causes the pinions 4, to rotate, and as the drum 6, and the pinion keyed to its hub, are prevented from rotating, the double armed piece 5 is caused to rotate, and with it the hollow shaft to which it is keyed. In this case the number of revolutions per minute of the hollow shaft is one-half the number of revolutions of the pulley, and the three speeds of the vehicle corresponding to this position of

of the double gear 4, around its axis. The pulley 1 is directly connected to the hollow shaft, and both turn, therefore, at the same rate of speed. The speeds of the vehicle for this position of the gear are 10, 15, and 20 miles an hour.

If the two members of the friction clutch be separated far, the gears 4 and 2 will get out of mesh, and the large gear 4 will engage the pinion 3. This position of the gear corresponds to a reverse motion of the vehicle, and three reverse speeds may also be had by shifting the belt. When it is desired to completely disconnect the engine from the driving wheels the gear 4 is held in a position midway between gear 2 and pinion 3.

We have endeavoured to explain as clearly as possible what appears to be rather a complicated gear. We are assured, however, that the complication is only imaginary, but that in practice it is easily handled, and has proved itself effective and that, while increasing the number of forward speeds and backward motions available, the change gear is not only silent in its operation, but obviates undue strain or wear on any of the gear wheels.

FIG. 2.—GENERAL VIEW OF LUFBERY CAR.

FIG. 3.—PART-SECTIONAL VIEW OF INTERMEDIATE SHAFT-LUFBERY CAR.

the gear and clutch mechanism are 5, 7½, and 10 miles per hour.

If it is desired to run the vehicle at a higher speed, the brake on the drum 6 is released, which engages the clutch members. Drum 6 is now fast on the shaft, the same as the double-armed support 6, and there can, therefore, be no rotation

The steering handle also presents a novel feature in that by pressing it in a downward direction the jockey tightening the driving belt is raised, so putting the motor out of gear, while by continuing the pressure two hand brakes on the hubs of the rear wheels are applied. We understand that Mr. Lufbery is anxious to arrange for the construction of his type of vehicle in England, under licence.

CORRESPONDENCE.

TRACKS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I notice a correspondent in last week's issue, who had not the courtesy to sign his name, has thought fit to make some remarks about my going to Canning Town track instead of endeavouring to put the forty miles in the hour on the Crystal Palace track.

Why on earth he should say it is not fair my putting up a forty miles an hour record on the Canning Town track I cannot conceive. If I like to put a record up on a track at Timbuctoo I do not see why it should worry or annoy "A. B. C."

I shall be delighted to endeavour to accomplish the forty miles in the hour on the Palace track if "A. B. C." will kindly supply me with a new set of tires for the purpose, as one of my reasons for going to the Canning Town track was, because the surface, being less rough, it was not so liable to scrape my tires to pieces. If also "A. B. C." will kindly go to the Palace track and flatten out a big bump on one of the bankings which has developed recently he will further assist in the possibility of riding on the track at a big speed.

In comparing the two tracks I would like to point out that the authorities of the Canning Town track had refused, prior to my going down there, to allow motorists to ride, on the ground that they did not consider it safe, and surely if I cared to run the extra risk on this point with the idea of saving my tires on the point of surface, there can be no loss of any possible credit which may be due for any performance done on the track. One might just as well say that the cycling records put up on the Catford cycling track should not be recognised because a larger proportion of races are run and records made at the Crystal Palace.

Regarding the point raised by "A. B. C." regarding the possible discrepancies in the value of performances on the various tracks, I shall be very glad if he will kindly inform me what is the actual value derived from such performances. My own personal opinion has always been that the man who will cover the greatest distance on a motor-cycle on the track is the man who is willing to run the greatest risk, provided, of course, he has a good and fast machine.—Yours truly,

CHAS. JARROTT.

14, Regent Street, S.W., October 9th, 1900.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—"A. B. C." raises a point which, as an old cycle rider, I feel interested in. No records ought, in my opinion, to be recognised unless run on a track selected by the authorities for the purpose. One track may help the rider; another provide turns and a bumpy surface. Hence the difference in value between the performances on various tracks. Yours, etc.,

London, E.C., Oct. 9th, 1900.

EX-CHAMPION.

THE SKIDDING TROUBLE.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—One of the terrors of the nervous motorist is skidding; and many drivers confess with regret that winter must be almost an off-season to them, so much do they dread motoring over greasy roads. It would be useless to deny the existence of these risks. In part they are due to the use of rubber and pneumatic tires, and must be set off against the comfort obtained by the use of these instead of iron tires. If we are to keep rubber tires it is difficult to see how side-slip can be wholly avoided. Non-slipping ridges, such as are fitted to cycle tires, would scarcely be of use on large cars, and they would wear away quickly. Whether a different section of tire instead of the circular shape now in vogue would be advantageous remains to be proved—and that by hard practice rather than theory. A matter, however, which should weigh with designers is the length of the wheel base—that is, the distance between the front and rear axles. It may seem desirable from many considerations to have this as short as possible; but if

steadiness and easy steering be desired, it is well that the wheel base be of goodly length. At the present time there are several cars on the market which, I think, would be less prone to skid if they had longer wheel bases. Yours truly,

Dublin, October 8th, 1900.

H. P. R.

MANCHESTER TO LONDON.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I am about to have a tandem motor tricycle of my own, which I intend to use for business purposes. Next month I hope to drive it from Manchester to London, and I should probably have taken that same road through Coleshill (which I have so unsuccessfully tried to avoid) had it not been for the kindness of Mr. Edgar Soames in answering my query on that point. This time I hope to be more successful, and I hope you will allow me, through your columns, to thank Mr. Soames for his timely guidance.

Weston Rectory, Norwich.

Yours truly,

October 7th, 1900.

J. REGINALD EGERTON.

In the lifeboat procession to be held in Dublin to-day (Saturday) several motor-cars will take part.

At Lynn, on Monday, Robert Gale, in the employ of Mr. F. Morris, was fined £2 inclusive for furiously driving a motor-car on September 16th.

WILLIAM MCARDLE pleaded guilty at Bournemouth last week to driving a motor-car without a light on September 15th, and was fined 5s. and 5s. costs.

MISS DALY, of Terenure, enjoys the honour of being the first practical lady motorist in Ireland, she having lately become the possessor of a De Dion voiturette, which she now drives herself.

THE Bracegirdle Cycle Company, Ltd., of the Mercury Cycle Works, Alexandra Road, Manchester, are keeping up with the times, having laid themselves out to undertake repairs to motor-cycles and cars. They also keep a stock of petrol and motor accessories.

A RUNAWAY motor-car, near Uxbridge, is reported to have dashed down a hill the other morning and through the front window of a villa, where the family were just sitting down to breakfast. The "autocrat at the breakfast table" is familiar to every reading man, but the autocar is a different thing altogether.

THE Council of the Liverpool Self-propelled Traffic Association has decided to prepare a report dealing with the present condition of the heavy motor-vehicle movement in France, and for this purpose the hon. secretary of the Association, Mr. Shrapnell Smith, is this week attending the Poids-Lourds competition in Paris, organised by the technical commission of the International Exhibition.

THE S. T. Rubber Tyre Company, of Westminster and Manchester, have, we learn, amalgamated with the Challiner and Willoughby Tyre Company, Limited, of Manchester. The name of the new company will be the Shrewsbury S. T. Challiner Tyre Company, Limited, the capital being £82,000. Business will be carried on in London and Manchester as hitherto, and Lord Shrewsbury will be the chairman of the new concern.

At Chelmsford Petty Sessions last week Robert Charles Knights, engineer, of Chelmsford, was summoned for driving a motor-car after dark without a light at 10.55 p.m. Mr. Drake, a messenger for the defendant, expressed his regret at the latter's inability to attend. A fine of £1 and 7s. 6d. costs was imposed.

THE pneumatic tire appears to be the element that is giving the most concern to motor-car manufacturers and automobilists just now. Mr. J. T. Wicks, of Hermitage Road, Finsbury Park, has lately put on the market a new moulded air tube for pneumatic tires which he claims overcomes many of the difficulties hitherto experienced. The advantages of the new Wicks tubes are said to be that they are seamless and jointless; the rubber is vulcanised under enormous pressure, hence the material is consolidated and all defects obviated; the tube is moulded complete, the air valve being vulcanised in position.

SOME INGENIOUS DEVICES ON MR. KENNARD'S NAPIER CAR.

CONSIDERABLE interest was displayed in Mr. Kennard's Napier car by the members of the Automobile Club during the past week. Since Mr. Kennard took possession of his car he has had considerable experience with it, with the result that he has fitted the vehicle with several little "tricks"

of his own. Two of these we are able to illustrate herewith. The first is a power-driven pneumatic tire inflator. To inflate a 90 millimetre tire, to say nothing of a 120, is, as may be imagined, no light task, and Mr. Kennard has brought the engine into requisition for this purpose. The plunger of the inflator, instead of being operated by hand, is driven off the motor by an eccentric. The inflator proper is, of course, held in a fixed position, a long flexible tube forming

the connection between it and the valve of the tires. A pressure-gauge is also fitted in connection with the device, and this indicates the degree of inflation. In addition it is so arranged that when a pressure of 80 lb. is reached a safety valve is opened automatically, so preventing over-inflation of the tire.

The second device illustrated is a bell clumped to a spoke of the road wheels just under the rim, and actuated by a lever which is well above the road when the tire is inflated, but is compressed

when the tire is punctured and flattened to the rim. The first specimen of this "puncture-notifier" is capable of improvement, but contains the germ of a useful idea. It is easy for a motorist to proceed some distance, and meanwhile damage his inner tube, before becoming aware of a puncture, and this new device should obviate that undesirable contingency.

HEAVY STEAM VEHICLES IN AMERICA.

WE have already referred in a previous issue to the heavy steam vehicle built at the Cooke Locomotive Works, at Paterson, N.J., under the Thornycroft patents, and to the fact that steam lorries on the Simpson-Bodman system are to be built by the Milwaukee Automobile Company under the direction of Mr. Bodman. It would seem that the advantages of such vehicles are beginning to be recognised in the United States, for we learn that still another concern—the White Engineering Works, of Indianapolis, Ind.—has taken up their construction. The White steam lorry, the first one of which has lately been turned out, has, states the *Horseless Age*, a capacity of from 2 to 2½ tons and a normal speed of five miles an hour. The main framing is constructed of channel steel, and the floor or platform overhangs the wheels in all directions. The wheels have a diameter of 40in., and 4in. steel tires, both in front and rear, are used. The steam generator is located centrally in the fore part of the frame. It is of the marine water-tube type, and is coke-fired. The water-level of the generator is maintained automatically, and it is only necessary to keep the water tank supplied, for which a steam syphon and hose are provided. The fuel tank, made of sheet steel, extends across the front of the cab, and opens in front of the driver. The engine and gearing are located below the floor. The engine has either three or four cylinders, is single acting, and of the compound type. The cranks are enclosed in an oil bath. The engine, although compound, can be worked with high pressure steam in all the cylinders, and is, in fact, always started up in this manner, the pawl, controlling the compounding valve, being operative only when the vehicle is in motion. The engine is started and governed by a controlling lever. In the central position of this lever steam is shut off from the cylinders. If the controller lever is pushed forward it will cause the cylinders to be drained, and admit steam to the cylinders, the admission being proportional to the motion of the lever. To back the vehicle the controller lever is thrown backwards; it operates and locks the reversing gear automatically, at the same time tending to the draining as before. In addition to the gear for ordinary speeds the vehicle is provided with a hill-climbing gear, which increases the demultiplication three times. This gear works in an oil bath, and is operated by a simple lever. Roller chains are employed to transmit the power from the differential shaft to the driving wheels. The dimensions of the lorry are: 17ft. in length, 6ft. 8in. in width, and 9ft. in height. The floor is about 46 inches above the roadway.

A PUBLIC service of motor-cars is about to be started between Mons and Beaumont, Belgium. The vehicles will be able to accommodate twenty passengers and a quantity of luggage.

IN our issue of the 4th August last we gave some particulars of the successful run to Brighton of a Joel electrical voiturette on one charge of the battery. We learn that the National Motor-Car Syndicate were submitting the car to another trial over the same route on Thursday, starting from the Automobile Club, details of which we hope to publish next week.

THE New York Motor-Vehicle Company have just finished a motor public passenger omnibus. The present model is said to be the outcome of a considerable amount of study and investigation, as the company sent their engineers to Europe to carefully look into the merits of the different motors at all the great manufacturing centres, with the result that they have adopted steam as their motive power. Their model omnibus is made to seat twenty passengers, and differs in style and size from anything so far made in America.

HERE AND THERE.

THOSE interested in the development of the motor-car industry and who are looking out for likely opportunities for profitable service next season should consider the Dukeries—that charming district in which many participants in the 1,000-Mile Trial would have liked to linger awhile. I hear that a kindly reception would be given the automobile in that district. At present a large number of horses are engaged in the trippers' traffic of the Dukeries, and they are frequently a cause of danger, often running away and otherwise misbehaving themselves. The dangers with the use of the motor-car should be materially lessened, and some of the posting proprietors in the Dukeries might be approached with a view to the institution of an experimental service.

AN Irishman living in America has been attempting to write poetry, and although his effusion will not add much to the gaiety of either the Old World or the New, it will probably be welcomed by the Poet Laureate. For the rhyming of "with her yet" with "voiturette" is certainly worthy of the official poet of Great Britain. Says the rhymester referred to:—

Fair Phyllis, once the humble slave of tennis,
Went forth to freedom in the throes of golf.
The shackles worn in courts of chalk and netting
Were straightway loosed and taken off.
And then a season's whirl of tees and cleeks and drivers—
A season's joy that lingers with her yet—
And glad, she views the shackles reappearing
Heart-forged within a little voiturette.

THE newspaper notices of the 1,000-mile Trial in the scrap books of the Automobile Club measure 504ft. in length, exclusive of the lengthy reports which appeared in the strictly automobile press. Even now the floodgates of writing on the subject have not ceased, and in the *Engineering Magazine* for October Mr. Worby Beaumont has an article on the event. It is written in a strain familiar to all who have heard Mr. Beaumont's well thought out speeches on technical subjects, and I quote the following lines as a typical instance of his regard for completeness in observations:—The total number of the revolutions made by the road wheels of the competing vehicles in covering that 60,000 miles was about 40,000,000. The wheels and axles may, however, be said to be very simple parts, so it may be mentioned that the collective revolutions of the crank shafts of the engines of the vehicles were about 70,000,000, and this means that the pistons of those engines made from 210,000,000 to 216,000,000 strokes, and the admission and exhaust valves not less than about 200,000,000 millions of strokes, or openings and closings. It needs no argument to show that such enormous numbers of repeated wear-causing and strength-testing operations could not have been made with machines very unfit for their work, or without teaching many lessons which, when fully utilised by those manufacturers who are susceptible of instruction and capable of putting it into practice, must lead to far-reaching developments.

THE advent of the Automobile Club into Monmouthshire should help the automobile movement in that county, and, as a matter of fact, Dr. Lloyd Smith, of Monmouth, ordered a Motor Manufacturing Company's phaeton during the recent short tour. It is a pity the tour could not have been extended into Glamorganshire with a view of easing the mind of some of the City Fathers of Cardiff. At the last meeting of the Council, Mr. Good proposed that the Cardiff, Whitechurch, and District Motor Car Company be given licences for three motor-cars to ply between North Road and Whitechurch, but the motion was lost, only seven councillors supporting and a score voting against the proposal. And this, after Messrs. Jacobs and Thomas, on behalf of the Motor Car Company, had shown the need for more facilities for the public.

THIS need of education in motor matters is as desirable for town councillors and local magnates as for horses and mules—in fact, it is even more necessary. Horses suffer from fright, but councillors are subject to prejudice.

LORD BRASSEY is notable among notabilities. As a Colonial Governor, a distinguished man of affairs, and a keen sportsman, his reputation goes beyond the British Empire, and his accession to the ranks of automobilists is matter for congratulation. Like Lord and Lady Llangattock he is a yachtsman who has sailed in many seas, and the "Voyage of the Sunbeam," by the late Lady Brassey, will long remain a national volume. On Monday he was at The Hendre, Monmouth, where he saw some fine automobiles and had opportunity of learning much while taking trips on Mr. Rolls's Panhard, Mr. Hargreave's Daimler, and Mr. Edge's Napier; anyhow, on Tuesday he was back in London, and purchased from Friswell's a De Dion voiturette, thus testifying to his interest in modern methods and manners.

IN the show rooms of the Motor Manufacturing Company, on Holborn Viaduct, is the motor-bicycle on which Mr. Pennell accomplished his record ride over the Alps. Mud-bespattered and road-stained it is exciting considerable interest, and I fancy the exploit should lead to many inquiries about the Werner machine. What an interesting conversation Miss Bacon and Mr. Pennell could have on the subject.

THE partiality of Gloucestershire horses for motor-cars has received exemplification in the case of Mr. Edge this week. He was on his way from Lord Llangattock's place on his Napier car, and had passed two heavy horses drawing a farm wagon. A few yards further on another van was coming in the opposite direction, and the driver signalled Mr. Edge to slow down. This he did. The horses previously passed came along and smashed up against the Napier car. The foremost horse then went to the front of the car and kicked up behind, destroying the lamps and radiator. Fortunately no one was hurt, although the motorist probably felt more fully convinced than before that horses are strangely-behaved creatures. Whether the equine fancied he might have obtained a comfortable place in front of the car is not reported; certainly he made it warm for the driver. Anyhow, Mr. Edge's progress was not seriously impeded, as will be seen from the account of the visit to Monmouth recorded on another page.

IN Hyde Park on Sunday a lady reader of the *Journal* saw fifteen motor-vehicles—two driven by ladies—during the course of a short stroll.

THE second 16 h.p. Napier car is finished, and was taken for its first run on Sunday. Mr. Jarrott and Mr. Napier were aboard, and along the Ripley Road it careered at a good speed and in fine style. From what I hear the car is likely to prove somewhat faster than that of similar power owned by Mr. Edge. A contest between the two would be interesting. The new car has been constructed to the order of Mr. Mark Mayhew, who will probably send it up Porlock Hill in the beginning of November.

LAFAYETTE, the conjurer who recently puzzled London, dismounted from his automobile when performing his tricks; Mr. Coles at the Agricultural Hall was content to steer his car with his feet, folding his arms in the meanwhile. Combining both feats and developing an originality of his own, a German circus juggler is now startling his audiences from a voiturette. Standing in this and steering with his feet he spins his motor-car around the ring at a smart pace, and continues juggling with balls, etc., the whole time. Evidently the uses of the motor-car are infinite, and it will probably have a place in some of the pantomimes during the coming season. LOLIUS.

MR. F. F. WELLINGTON is making a reduction of 25 per cent. on all repairs executed for members of the English Motor Club.

MISS EMLÉN S. BLYE, of Chicago, underwent the examination for automobile operators a few weeks ago, and was granted a certificate. She announced that she was taking the examination for business and not private uses, and that she intends to conduct a school of instruction, teaching other ladies the method of managing and operating motor-cars.

MOTOR-CARS ON THE CONTINENT.

Public Service Work in Spain.

HAVING on several occasions been requested by readers of the *Motor-Car Journal* to furnish them with a list of public automobile services, I venture to think that the subjoined particulars of such services in Spain, and which were recently published by the *Vélo*, will prove of use to them. As I have already mentioned in these columns, the industry in Spain—or rather the movement, for the industry actual is infinitesimal—is progressing more particularly in the direction of public and transport services, and to-day the Peninsula holds its own well in this respect. The *Vélo's* correspondent at Madrid announces that in the province of Corogne a couple of companies are working services—the one between Corogne and Santiago, and the other from Corogne to Betanzos and Ortigueira. In Asturias the *Compania Asturiana de Automoviles* run cars from Oviédo to Luarea, and from Avilés to Gijón. A line from Palanquinos to Valencia de Don Juan is the sole service in the province of Léon, but in Valladolid three services exist, these being Valladolid to Puebla de Sanabria, Valladolid to Zamora, and Valladolid to Fuente Sanco. In Ségovia, Ségovia is connected with the Granja and Arévalo by automobile services, and in Guipuzcoa cars run between Zumaga and Zaranz. The province of Logrono is blessed with one service only, that between Logrono and Soria y Burgo de Osina. Lérida also has but one line, and that runs from Lérida to Balaquer. Both Tarragona and Barcelona possesses a couple of services, those of the former province being from Tarragona to Reus and Valls, and of the latter Ripoli to Puigcerda, and Papiol to Rubi and Tarrasa. Services also exist at Lugo, Tuy, Burgos, from Grenada to Motril, from Malaga to Nerja, and in the provinces of Seville, Cadiz, Huesca, Badajoz, and the Balearic Islands. According to reports these various concerns prosper exceedingly, many of them paying dividends of as much as 30 per cent. If only in that respect these companies are happier than any I have had experience with, for big dividends are not so easy to pay, and I very much doubt whether any concern exists outside Spain which can point to such a figure.

Count Champrobert's Mishap.

It is reported from the Auvergne district that Count Champrobert, who has so often figured in automobile races, has been the victim of a serious accident in the neighbourhood of La Charité. The incidents giving rise to the mishap were of so curious a nature that I give details. At the moment that the Count and his engineer were about to mount a hill and were travelling at full speed a couple of horses galloped out from a field bordering the road, and one of them ran directly in front of the car. His appearance was so sudden that the Count had no time to apply brakes, and the 30 h.p. racing machine and the noble beast collided with a terrific shock. The vehicle was projected against a tree and the two occupants thrown out. Count Champrobert received a bad cut on the leg and many bruises, while the engineer also suffered injuries to one leg. Both succeeded in reaching La Charité, and after their wounds were dressed the two unfortunate *chauffeurs* set out for Paris by train. The car was badly damaged, and presumably the horse also.

Caniveaux.

EVERY automobilist who has toured in France knows only too well the dangers of the *caniveau*, that paved water-course which traverses the route sometimes in the least expected places. If one is ignorant of this feature of French roads, but little attention is bestowed upon the thin line which suddenly appears upon the perfect surface of the route, and it is not until one has closely approached that the sharp drop and nasty strip of *puvé* causes a hasty application of the brakes. A violent bump, a clattering over the stones, succeeded by another jolt, and one is through, with the loss of a nut or so, if nothing worse. Only too frequently are serious mishaps caused by these

abominations, not always at the moment itself, but later on, when some part, shaken loose by the shock, no longer keeps place. Pass as slowly as one may through a great number of these *caniveaux*, the bumping and jolting is considerable, and when one is running at any speed the danger is really great. Unquestionably more accidents have been caused in races by the presence of *caniveaux* than by any other cause, for when travelling fast a car literally jumps the obstacle, and springs, tires, wheels, and axles have all been known to give way under the tremendous shock. These death-traps—for it is not too strong a term for them—are usually to be found in the immediate neighbourhood of towns and villages, but occasionally they are encountered far afield from inhabited spots. Sometimes they show themselves boldly, and one has ample time to reduce speed, but more often they secrete themselves with great cunning, and present the appearance of a vague shadow crossing the route. It is then more particularly that they are dangerous, and after being trapped a few times one slows up at the shadow thrown upon the road by every branch. Generally speaking, they are harmless in a village street, for there the route is in itself so bad that one progresses slowly and continually on the look-out for soft places.

Some Hints.

WHEN entering or leaving towns and villages one should scrutinise the road ahead with every care, for, as I have already said, it is there that these terrors of the *chauffeur* abound. As a preventative of excessive speeds in the neighbourhood of towns, they are, in combination with a liberal supply of *puvé*, most efficacious, but they ought to be marked, for in order to teach the automobilist moderation it is useless to commence by killing him. Nominally used as watercourses, they are actually employed as automobile traps, and strong measures should be taken to remedy this state of things. Not by removing or even materially changing the *caniveaux*—no, I do not for one moment advocate such a course, but I do most emphatically agree with the scheme of marking all these dangerous spots, as proposed by the committee of the Moto Club. A couple of signboards, similar to those affixed by the Touring Club of France to indicate the presence of a dangerous descent, might well be placed some fifty yards on either side of the more treacherous *caniveaux*, and this the Moto Club expresses its intention to do. Following the indication shown by the notice board, the automobilist will then know the character of the *caniveau* he is about to encounter, and will act accordingly. But if dangerous in the daytime, these traps are infinitely more so at night, and I hope that the club will see its way to arrange for the lighting of a lantern upon the sign- posts after dark. I fancy this could well be done in the case of those placed in the neighbourhood of inhabited spots, and at a very slight expense. For those further afield, well—I fear lighting would be a serious difficulty, but these are in the minority. In the Gordon-Bennett cup race Charron came to grief over a *caniveau* while travelling at nearly sixty miles an hour, and he must be considered fortunate to have escaped with no personal injuries and such comparatively slight damages to his car as a doubled-up back axle and a wrecked pump. The *caniveau* at Saint Jean-de-la-Ruellis, on the route de Chateaudun, should be one of the first to be labelled, for it is as deep as it is well concealed, shaded as it is by overhanging trees. Let the Moto Club get on with its task, and it will earn the gratitude of all automobilists. So good luck, then, to the enterprise, and a speedy completion.

The Moto Club and the "Vélo" Competitions.

THE membership of the new French organisation known as the "Moto Club" continues to increase, and has now reached the satisfactory figure of 658. As is well known, the club really emanated from the offices of the *Vélo*, and that paper may be considered as the official organ of the society. It appears, too, that the automobile races and competitions formerly promoted by the *Vélo* will henceforward be

organised by the Moto Club—at least those of them for which the necessary official permission can be obtained. The first of these events which comes under the club's care is the competition for alcohol motors, now being organised to take place on the 28th instant. Early next year a couple of competitions for tires will be held with a view to solve some of the difficulties unfortunately so manifest in this direction. The first of these events will be styled the anti side-slipping competition, and the second "la roue élastique." These, it is to be hoped, will bring forth excellent results, for the troubles and dangers of pneumatic tires are very serious, and call for the undivided attention of makers in order to surmount them. If only we could obtain a tire as resilient as the "pneu," and free from all its puncturing and side-slipping eccentricities, what a boon it would be, and what a saving of bad language! Let us hope that the Moto Club's competition will bring us a step nearer to this ideal at any rate. By the bye, the new society goes into its premises at 4, Rue Meyerbeer, Paris, next door to the *Vélo*, on the 15th instant.

Motor-Cycle Racing in Paris.

A TWENTY-KILOMETRE motor-cycle race was included in the list of events at the meeting at the Parc des Princes track in Paris on Sunday last, the starters being Beconnais, Rigal, Fossier, Loste, Demester, Gasté, and Bertin. At the first the race appeared to be merging into a struggle between the two first named. Bertin was the first to give up owing to carburation troubles, and then Rigal gave the spectators a surprise, his motor coming to a sudden stop. It seemed then almost a walk-over for Beconnais, but at the fourteenth kilometre one of his tires burst, and although he endeavoured to struggle on for a lap or so he had eventually to give up, Gasté also retiring. All interest was now taken out of the race, Demester coming in first, followed by Loste and Fossier.

THE BRITISH MOTOR TRACTION COMPANY.

THE first ordinary (statutory) general meeting of the shareholders of the British Motor Traction Company, Limited, was held on the 4th inst. The secretary (Mr. Charles Osborn) having read the notice convening the meeting, the chairman, Colonel Harris, said the meeting was called in accordance with the requirement of the Act of Parliament, and it enabled the directors to make the acquaintance of the shareholders. He had, however, very little to tell them. The reconstruction had been almost perfected, but further applications for shares were being received every day. They might take it that the reconstruction would be successfully carried through; in fact, its success was already assured. It would be remembered that at the last meeting of the old company the directors intimated that they were going to exercise their rights to take legal proceedings against infringers of their patents. Writs have been served in respect of some of these cases, and the Board were advised that they had a strong position in regard to them. As to other business, they were organising sales, and had reason to believe that the company would be a success. Mr. Monkton said he had no intention of entering into the past affairs of the company, but he wished to know to what extent the shareholders of the old company had come forward and applied for shares in the new. The Chairman said hardly a day passed without fresh applications coming in from shareholders under the reconstruction, and out of the 4,500 shareholders in the old company, a large proportion had come in—about 3,000 had already applied. A shareholder asked if Mr. Harry J. Lawson held all the deferred shares. The Chairman said that gentleman held a large number of them. He also added that Mr. S. F. Edge, who was one of the late committee, had since been appointed a director of the company. Mr. Edge said the position with regard to organising the business was perfectly clear. It might be remembered that at the meeting at the Hotel Cecil he spoke as a member of the committee, and after that he was asked to join the Board, which he was very pleased to do, because his interests in the company were very large, not only as a shareholder, but as a licensee in connection with companies which had paid the British Motor Company more than anyone else. Therefore they were very interested in seeing that the patents were upheld, and he told the meeting that he thought if money were not forthcoming for that purpose the sooner they wound up the better. But he was happy to say that shareholders had come forward. At present they were engaged in making up their list with regard to the infringers, and he thought he might say there was no motor company in the United Kingdom which was not infringing one or other of their patents. There had recently been introduced in this country a large motor carriage of German make, and for which it was claimed there was no infringement. That might be true, speaking broadly, but a "cooler" was employed, and this company would be in a position to call for its removal, or for the payment of a royalty. The Board were now preparing a list to submit to counsel respecting the various infringements, and they

would take their advice as to which patents they would sue under. His opinion was that it would be as well to fight on the minor patents first, at any rate until the judges were sufficiently educated to the fact that these very small differences on motor-carriages really made all the difference between success and failure. The water cooler, for instance, might not mean very much in the case of the ordinary user, but when they came to the large buses and other heavy vehicles they did not travel through the air fast enough to keep the water cool, and the result would be that they would emit a large amount of steam or vapour, and that was illegal. So far as the patents and their infringements were concerned, shareholders would see a very decided movement on the part of the company when the Long Vacation was over. The Board would write specifying the infringement, and expressing their willingness to grant a licence, but in default of some arrangement being made no doubt writs would be at once issued. With regard to the manufacturing part of the business, the difficulties were very great unless there were a large capital at hand. Anyone entering into the motor industry here to compete with the existing factories abroad must do it in a very big way. He must lay down a plant not for one motor, but for 10,000 of them, as they did in France. The only way to proceed, if they were not prepared to sink about £200,000 on stock and plant, was to let the business grow gradually, and that, it was hoped by the Board, would be the case with them. But he looked to the patents as the main source of income to the company. In reply to a shareholder, Mr. Edge said the company had small works at Coventry, which had been used principally for experimental purposes. Dr. Drysdale moved a vote of thanks to the chairman and directors for the way in which they were carrying on the business. Mr. W. Davies seconded the motion, which was carried unanimously. The proceedings then terminated.

FATAL TRAP ACCIDENT AT EASTBOURNE.

AN inquiry into the circumstances of the death of Mrs. Mary Underwood, which occurred at about noon on Wednesday last week, owing to injuries consequent upon a collision on the Pevensy-road, Eastbourne, on the previous Monday afternoon, was conducted on Friday last by Dr. W. A. Dow, Deputy Coroner for East Sussex, at the residence of the deceased. Henry Underwood, husband of the deceased, stated that he was out driving in a phaeton on Monday afternoon with his wife and daughter, and was returning from Pevensy to Eastbourne at about four o'clock. They had turned a corner of the road at Hide Hollow, at the top of the declivity before the ascent to the Langney Cemetery, when the horse suddenly sprang into the bank at the side of the road, and witness was pitched out. The horse then bolted with witness's wife and daughter, and he saw no more of it. The horse was nine years old, and as quiet as a lamb. It was not frightened of trains, but it had an objection to motor cars. As the horse went into the bank the reins broke. Edward Williams said he was coming from Stone's Cross toward Eastbourne, driving a single-horse landau, when he heard a horse coming up the hill toward Langney Cemetery, the horse being at a canter. He pulled aside, and as the trap passed he noticed that the reins were hanging loose at the side, and that Mrs. and Miss Underwood were apparently helpless. He drove after the trap, and observed the collision with a van which had drawn clear on the near side to give it full space to pass. The trap caught the wheels of the van, and Miss Underwood was pitched out, while the trap was overturned right on to Mrs. Underwood, who fell underneath. With the assistance of Mr. Harrison, who was in the landau, they got Mrs. Underwood out. She was lying on her back unconscious in a pool of blood, and they put her on a rug and conveyed her to a neighbouring cottage. Subsequently Mr. Underwood, who was thrown out of the trap before witness saw it, and Miss Underwood were helped up for conveyance into Eastbourne, and witness drove off. The horse was going so quietly up the hill when he first saw it that had he known it was a runaway and could he have reached the reins he could have stopped it. Miss Underwood said she was driving with her father and mother as described, when they heard the motor-car coming up behind, and the horse taking fright, ran into the bank, her father being thrown out. The horse then ran away. It was quite impossible for them to regain possession of the reins. They passed several vehicles before they collided with the van, and witness and her mother were thrown out. Henry Dakins, motor-car driver, stated that on the afternoon in question he was driving a 4 h.p. motor char-à-banc. He was driving from Pevensy towards Eastbourne, and he came round the corner at Pevensy-lane at a walking pace, the engine being ungeared and the brakes being on. The engine was not racing, the accelerator having been lowered. As they turned the corner he observed a gentleman driving a trap towards Eastbourne about 150 yards in front of witness. The gentleman appeared to have lost control of the horse, and witness stopped immediately; and later he saw the horse and trap proceeding up the Cemetery hill at a gallop. From the corner of the lane until he stopped the car the engine had never been in gear, and when running down hill the engine was practically silent. The engine was put out of gear at the top of the incline before they reached the corner. He had never been concerned before in an accident with a horse startled by the noise of the car, and in fact not one horse in fifty took any objection to the car. He never got less than 150 yards of the trap. The action of the brake was quite noiseless. Witness added that he passed Mr. Underwood's horse with the car on the way to Pevensy, and the animal took no notice. Mr. H. Plumb, the foreman of the jury, after consultation, said it did not appear how the motor car was concerned in the accident at all. It seemed that with the breaking of the reins Mr. Underwood lost control of the horse, and he further

thought that great credit was due to the motor-car driver in pulling up at once. A verdict was then returned to the effect that death was due to injuries sustained consequent upon being thrown out of the trap, and that the occurrence, with which the motor car had nothing to do, was purely accidental.

OBSTRUCTING A MOTOR-CAR.

At the Abingdon County Petty Sessions, on Monday, Mr. Harry W. Sowden, farmer, East Hendred, was summoned by Mr. William G. S. Hynde, a law student, of Abingdon, for obstructing the passage of a motor-car along the Abingdon and Steventon Road. Mr. Pryce prosecuted. It appeared that the complainant in a motor-car overtook defendant, who was driving home from Abingdon Agricultural Show on the 20th ult. He said the defendant allowed him barely room to pass, and when the two vehicles were opposite, defendant drew across the road, causing a slight collision, and the complainant, to get clear, had to run his motor-car upon the path. Mr. Sowden's version was that complainant drew level with the horse, and then, slackening speed, ran alongside to annoy him and frighten his horse. The case was dismissed.

A MOTOR-CAR COLLIDES WITH A TRAMCAR.

IN Aberdeen Police Court, on Monday, before Baillie Meff, William Bowman, engineer, was charged with having, on Saturday, 29th September, in Great Western Road, while in a state of intoxication, driven a motor-car recklessly and carelessly, so that it collided with a tramway car, damaging the car and injuring one of the horses. He pleaded not guilty. The driver of the tramcar stated that he was driving the car westwards along Great Western Road, and was just entering the Ashley Road crossing when he saw the motor-car approaching along the centre track. He blew his whistle and shouted as hard as he could, but the motor-car came right on, and, although he drew his horses to the side to prevent them from being injured, the collision could not be avoided. The car was damaged about the dashboard, and one of the horses injured. He considered that Bowman, the driver of the car, had had too much drink, and did not know what he was about. Another car driver and a conductor gave corroborative evidence. The magistrate said the charge had been clearly proved. A man who drove a motor-car must have a clear head, and it was a most dangerous thing for Bowman to act as he had done. He would have to pay 20s. fine, or go to prison for ten days.

FURIOUS DRIVING CASES.

At the Malvern Police Court last week Edward G. Sindry, Bristol, was charged with driving a motor-car in the Grange Road, Malvern, on the 26th ult., at a rate unsafe under all the conditions. Police-constable Miller said that on September 26th he was on duty in Church Street at about 7.45 p.m., when he saw defendant coming along the Grange Road in a motor-car at the rate of quite twelve miles an hour. Defendant turned into the lower part of Church Street, and the machine went very near the kerb. The speed was scarcely slackened at all in turning. There was danger from the number of people in the locality at the time going to a play at the Assembly Rooms, and at the rate defendant was driving he could not have avoided collision with anything that might have come across the road at the corner. No sound was made for warning. Defendant submitted that the type of machine he had, and its condition, made it impossible to do twelve miles an hour, and called Mr. Mayo, Malvern, as an expert, to support his statement. The clerk advised the Bench that the point for consideration was whether there were circumstances of danger to the public. The Bench thought a bad case had been proved against defendant, and imposed a fine of 40s. and 20s. costs.

At the Stockport County Sessions last week, Herbert Wm. Lee, Didsbury, who was represented by Mr. J. B. Oldham, was fined 40s. and costs for driving a motor-car at an excessive speed at Handforth. Captain Sykes said the fine would have been heavier if the road had not been a quiet one. Defendant should be given to understand that twelve miles per hour was the extreme speed he could go on a quiet road, and he must go much slower on a road where there was much traffic.

At the Sessions House, Boston, last week, Thomas Skinner, Norfolk Street, was summoned for furiously driving a motor-car on the Spilsby Road on September 16th. Mr. Gane defended. Sergt. Theaker said on the Sunday night in question, about six o'clock, he was on duty on Bargate Bridge, when he saw defendant approaching the bridge on a motor-cycle. He was then near Trinity Church, about 300 yards away. The motor-car was proceeding at a furious rate, with a cloud of dust all round it. Its speed was fully twenty miles an hour, and that rate was continued until 100 yards off the bridge, when the speed was slightly lowered. Witness asked Police-constable Davy to shout to the defendant to "go steady," and he did so. Defendant glanced round, but did not speak. He turned round on to the Horn-castle Road at twelve miles an hour. There were a number of people about at the time, and they were in considerable danger. Defendant gave no warning as he approached the bridge. Charles Ingham, Boston, who was on the pavement near the church, said defendant passed him at 20 miles an hour, and he could scarcely be seen for dust. Witness considered the pace was dangerous. Joseph Taylor, Fishtoft, gave similar evidence. He said defendant was travelling at a tremendous pace—he should think 18 to 20 miles an hour. Witness

never saw a motor go so fast before. Police Constable Davy corroborated Sergeant Theaker's evidence. In cross-examination he said defendant did not speak when he shouted to him. He had no time—he was going at such a rate that it took him all his time to look where he was going to. Defendant was sworn. He said he had had the motor seventeen months, and had never had an accident or caused one to anybody else. He was an expert driver. On the day in question he went for a run to Freiston Shore with his wife. The return journey occupied forty minutes, and he travelled up the Spilsby Road at 10 or 12 miles an hour. The roads were very dusty indeed. The wheels of his motor were very small, and threw up a lot of dust. Harry Palmer said on the Thursday previous to the Sunday in question he went out with Mr. Skinner on this machine to try and discover its defects. They went to Carrington. It would be impossible at present to get more than 12 miles an hour out of the car. Its cog wheels were very much worn, and in consequence it made a great deal of noise. Anyone seeing the machine and hearing the noise would probably think it was going at a tremendous pace; when in good working order it might be possible to get 15 miles out of the motor, not more. Mr. Gane submitted there was no evidence upon which the Court ought to convict. Defendant had his wife in front of him, and it was not likely he would drive at a furious or dangerous pace. Many people had an objection to motor-cycles, just as they had to bicycles when they first came out. The noise this machine made through being out of order, and the dust rising about it, gave the impression that it was going unduly fast, but ten to twelve miles an hour was not an undue speed. There was no evidence that that rate was exceeded—on the contrary, they heard that a cyclist rode some distance with the defendant and then shot ahead. The Chairman said it had been proved to the satisfaction of the Bench that defendant's pace was excessive, considering it was Sunday night and a number of people were about who were compelled to keep to the pavement because this motor was coming along kicking up the dust and making a hideous noise. It was not a bad case, but they must inflict a small fine as a warning. Defendant would be fined 10s. and costs.

At Hereford, Frederick Rough, cycle dealer, Commercial Road, was summoned for furiously driving a motor-car in King Street on September 11th. The case had been adjourned from a previous court. Mr. D. Allen appeared for defendant. Ernest Jones, the complainant, said on Tuesday, September 11th, he was holding a horse attached to a dog-cart, when defendant, who was driving a motor-car, came round out of Broad Street and ran into him. Witness's horse was close by Mr. Godsell's offices in King Street, near the pavement. Defendant was driving at the rate of nine or ten miles an hour. Cross-examined by Mr. Allen: There was a carriage and pair of horses coming up the opposite side of the roadway at the time. The collision was hard enough to mark the wheel of his master's trap, and moved it two or three inches. It swerved the horse to the pavement. He did not see the motor-car stop near Dr. Moore's. He did not try to pull the occupants off the motor-car. George Herbert Godsell said the motor-car was coming at a violent pace straight down King Street. Defendant tried to pull up when coming to the cart, and partially succeeded. By Mr. Shellard: There was not much damage, as the tires of each wheel were of indiarubber, and this checked the force of the collision. When it occurred defendant had reduced his pace to about five or six miles an hour. Joseph Makenson and William White offered evidence of a corroborative nature. For the defence, Mr. Allen stated that there was great confusion in the minds of the witnesses as to what took place. The Act of Parliament allowed light locomotives to go at the rate of fourteen miles an hour, but his witnesses would tell the Bench that the defendant was not going more than three miles an hour. The highest speed of this car would not allow it to go at a greater rate than eight miles an hour. By Dr. Moore's house he came to a standstill. The collision was a mere accident, and it was in consequence of the cab, but the cabman would tell them that he did not feel the car against his cab. Defendant could not get up speed until he had gone 100 to 120 yards. William Jordan, cabman, Monkmoor Street, said he went down Broad Street into King Street. At the corner of Broad Street he met defendant with a motor-car, which was not being driven furiously. He passed it before he got to defendant's trap. He did not know that his cab came in collision with the motor-car; if it did it was so slight that he did not notice it. When he turned round he saw that the car had collided with Mr. Godsell's trap. Defendant had the motor-car nearly at a standstill near Mr. Moore's house. Defendant said that on the day named he stopped near Mr. Moore's to change his gear, and from there to Mr. Godsell's he went at the rate of two miles an hour. He was told to keep to the left as there was a cab approaching. One of his back wheels caught the cab driven by Jordan, and this had the effect of throwing his car on to Mr. Godsell's trap. The Mayor said there ought to be great care in driving through the town, and especially in turning corners. Near his own house motor-cars often passed at a much faster rate than six or eight miles an hour. In the present case the Bench did not think there was furious driving, but they urged defendant to be careful when passing corners, and when driving where there was crowded traffic. The case was dismissed.

MR. FRANK H. BUTLER, of London, was the defendant in a police case at Dymchurch last week with respect to the furious driving of his motor-car, when, on the evidence of Corpl. Kemp and P.C. Sharp, he was fined £2 10s. for furious driving at that place. He was also summoned for refusing to stop when called upon to do so. Corpl. Kemp also proved this case, and defendant was fined 10s., with £1 8s. 6d. costs.

THE Motor-Car Journal.

Vol. II.]

LONDON, SATURDAY, OCTOBER 20, 1900.

[No. 85.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

IN celebration of the completion of the fourth year since the passing of the Light Locomotives Act of 1896, the Automobile Club is arranging a drive from London to Southsea on Saturday, November 10th. All owners of cars intending to participate should communicate with the Club secretary before the 8th prox. Number and time cards will be issued, and the route to Godalming will be via Whitehall, Great George Street,

Birdcage Walk, Lower Grosvenor Place, Hobart Place, Eaton Square, King's Road, Putney Bridge, up Putney Hill, Kingston, Esher, Guildford, and Godalming. At the old station goods yards, on entering Godalming, cards stating the time of arrival will be issued. Luncheon will be taken at Godalming, the Angel Hotel, the Red Lion Hotel, the Railway Commercial Inn, and the King's Arms Hotel supplying cold luncheons. From Godalming the route to Southsea will be via Milford, Hindhead, Liphook, Petersfield, and Cosham. At Hindhead the time occupied by each car in making the ascent will be taken. Non-stop diplomas will be issued in connection with the event, and a dinner will be held at the Esplanade Hotel, the Hon. J. Scott Montagu, M.P., presiding. On Monday the return journey will be made by Fareham, Wickham, Bishop's Waltham, Upham, Winchester, Basingstoke, Bagshot, Egham, Staines, Hounslow, and Brentford, to Horse Guards' Avenue, to Whitehall.

H.R.H. the Duke of York and Motor-Cars.

THE other day we had the pleasure of meeting Mr. Frank Morriss, of King's Lynn, who related with much satisfaction how he had recently surprised H.R.H. the Duke of York. Mr. Morriss drove a party to a shoot near Sandringham a few days back, and upon turning into a very narrow lane with one of his Daimler cars noticed H.R.H. standing at the end of the lane. The Duke signalled to him to stop, remarking, "My good fellow, you can't turn here." On the passengers alighting Mr. Morriss reversed his gear and backed out of the lane, to the great surprise and amusement of His Royal Highness, who subsequently inspected the car with much interest, and made several practical enquiries in reference to the same.

Norfolk Critics.

NORFOLK county councillors were severely critical and harshly condemnatory of motor-cars and automobilists at their meeting on Saturday. Two lords and half-a-dozen untitled persons declaimed against the new method of getting about the country, and not a tongue was raised in its defence. Mr. W. D. Everington urged that the county council should move the chief constable to action in the matter—a condition that, one member suggested, might be obtained by a reduction of salary. Failing that, an attempt to influence local M.P.'s to induce the

Government to reduce the speed of the "wretched conveyances" was proposed. Then Lord Kimberley dwelt upon the matter in a way that showed he requires half an hour's conversation with Lords Brassey and Llangattock.

"Somebody" to Catch Motorists.

"It was absolutely necessary," said his lordship, "that those who were at the head of the police should make the constables understand that it was their absolute duty to take every possible measure to put an end to a nuisance that was positively intolerable." Lord Kimberley added that somebody ought to be appointed to watch and catch motor-car drivers, although whether that "somebody" should be mounted on a racing Panhard car or travel on foot, his lordship failed to remark. The end of the matter was that nothing was done—not even a long resolution was adopted.

A High Sheriff's Confession.

FAR more important than the proceedings of the Norfolk Council was a discussion that has taken place at the Somerset County Council. The General Purposes Committee had considered a circular received from the County Councils Association inviting the opinion of the Council upon certain alterations proposed by the East Suffolk County Council in the Light Locomotives on Highways Order of 1896. Among the alterations suggested was that the maximum speed of locomotives on highways be restricted to ten miles an hour. In the discussion Mr. Neville Grenville observed that, in his position as High Sheriff, he had travelled over the greater part of the county on his motor-cycle, and had covered 248 miles in 14 hours 10 minutes. If he had had to trust himself to the tender mercies of the two railway companies he would have taken 40 hours 39 minutes. Thus he had saved 26 hours 29 minutes. He knew ten of his friends had gone in for such machines. In fact, motor-cycles were like a snowball—when once set rolling they would all have one, and not trouble the railway companies. Mr. J. F. Hall suggested that bye-laws should be made providing that motor-cycles should not travel at a greater speed than the express trains on the Cheddar Valley line. The Chairman remarked that the discussion had brought out the ingenious confession from the High Sheriff that he had been for the past three weeks violating the law, to which Mr. Neville Grenville replied that shows that "the law is a hass." The council resolved that the proposed alterations be printed and circulated among the members.

"Truth" and the Speed of Motor-Cars.

PEOPLE's notion of pace is generally very vague, remarks our contemporary *Truth*, in commenting on the speed of motor-cars. Parliament has limited motors to fourteen miles an hour, and the intelligence of divers county and borough councils has reduced this extreme limit to ten and twelve miles an hour. For the simple-minded horse or footman there is no limit. This scare about pace is utterly ridiculous. A car or a bicycle is much more

easily stopped than a horse and trap. Now some of these wise-ones who consider ten miles an extreme pace may be surprised to hear that Hurst, the professional runner, on a windy day and on a soft track, ran twenty miles in under one hour and fifty-six minutes. All through the race he never ran at less than ten miles an hour, though if anybody not knowing anything of pace had seen him moving, they would not have said that he was going fast. And yet he was exceeding the limit allowed by many a County Council bye-law to the motor-car.

The Joel Electrical Voiturette.

THE projected run from London to Brighton of a Joel electrical voiturette, by the National Motor-Car Syndicate, duly took place on Thursday last week. Although the speed at the end of the journey was not quite up to expectations the trip was made on one charge of the battery. The accumulators were recharged on Friday, and the return trip to London made on Saturday. Some slight modifications have since been made in the car, and a further run was to be made over the same route on Thursday last, when the distance was expected to be covered, not only on one charge, but at an average speed of ten miles an hour, the car being only geared up to a maximum of fourteen miles.

The Alcohol Motor Competition in France.

Le Critérium de l'Alcool, which is set down for decision on Sunday, the 28th instant, is receiving considerable attention, and the organisers have been favoured with quite a number of donations towards their list of prizes. First of all there is Prince Pierre d'Arenberg, who places £40 at the disposition of the Moto Club, and then no fewer than four agricultural societies present gold medals to swell the list of awards. Two other societies express their desire to present silver gilt medals, so it rather looks as though the few competitors—for there cannot be many entries—are likely to be inundated with awards. We notice that MM. Gobron and Brillié will be represented by a couple of vehicles, and MM. Daniel Augé et Cie. are also competing. It should prove a very interesting competition.

Motorists' Adventures.

IN another column, the Hon. Leopold Canning has an interesting article in which he records his impressions of his first long ride on an English road. He also gives his views of the police in no uncertain way, and is clearly of opinion that they should be put to some more sensible employment than catching motorists. Mr. Canning has done a good deal of motoring both in France and Ireland, and in the former country is evidently prepared for every emergency. He is a J.P., and a member of the leading automobile organisations in this country, and also of the Automobile Club of Nice, so combines a knowledge of motoring with magisterial practice which should secure a fair hearing for any automobilists who have ever had the pleasure of appearing before him, whether as defendants or complainants.

New Cars from Coventry.

QUITE a number of new types of motor-cars are just now in course of construction in Coventry. The Daimler Motor Company have, we hear, a new voiturette on the stocks, while the Motor Manufacturing Company are at work on two different types of voiturettes, and hope shortly to have a 12 h.p. car on the market. This high-powered car will have a countershaft running on roller bearings, while ball bearings will be fitted to all the road wheels.

Tests of Motor-Cars.

ONE of the features of the recent Automobile Exhibition and Tournament in Chicago was the utility tests of motor-vehicles made with a machine of the general design illustrated in the *Motor-Car Journal* of June 9th last. In this device the driving-wheels of a motor-car rested on two sup-

porting pulleys. The machine was secured by wire ropes to a series of links which transmitted the pull or tractive effort to a scale platform; friction in addition to the friction of the supporting shaft could be applied by a brake attached to the pulley in front of the machine. The apparatus was also arranged to be run by an electric motor, which allowed the friction losses to be obtained running the carriage from the motor. Tests were made on a Milwaukee steam automobile, a Hewitt-Lindstrom electric delivery wagon, and a Rambler petrol carriage; but, states the *Horseless Age*, the apparatus was so heavily and crudely constructed that it would seem doubtful if results obtained therefrom would be exact or comparable.

In Switzerland.

AUTOMOBILISTS have their grievances in Switzerland, as indeed they have in every country, and if oppressive measures are to be successfully combated, united and vigorous action must be taken against them. This time it is in the canton of Grisons that the trouble has arisen, and the State Council has actually passed a law forbidding the circulation of motor-vehicles within that province. This is just a little too severe, and Swiss automobilists are up in arms against the Council, and intend to resist with all possible energy the enforcement of the ridiculous measure. If the roads are not made and maintained for the express purpose of facilitating the circulation of all types of vehicles, for what do they exist? The ground they occupy would be more profitably and ornamentally utilised for fields if the routes are to be barred for traffic, and as the Swiss Automobile Club expresses it, "this prohibition is worthy of a council of Sioux chiefs, and not of a State Council of a Swiss canton." It is to be sincerely hoped that the efforts of the A.C.S. will be successful, and that the law will be shortly repealed.

Lights on Vehicles.

AT the last meeting of the Midlothian County Council a petition was laid on the table from the Scottish Automobile Club relative to the council's by-law regulating the lighting of vehicles, and praying that measures be taken to have this present inadequate law amended so that all vehicles should be compelled to exhibit lights in the direction of which they are proceeding or when standing. The chairman explained that their by-law enacted that all vehicles going faster than a walking pace should carry lights. Mr. J. M'Hutcheon Dobbie, Dalkeith, said he was not aware of a single accident having accrued from this by-law. The chairman observed there was one man killed last year. Mr. Dobbie further said that if they adopted universal lighting of vehicles they must adopt the lighting of pedestrians as well. The Automobile Club were the last people in the world who should send in a petition of this kind. The Council ultimately resolved to reply that they did not see their way to change the by-law.

Motor-Cars for Haulage.

THE Val de Travers Asphalte Company seem to be satisfied with their experiment in heavy haulage by automobiles, and their steam vehicle was seen along Holborn the other day—an object of much curiosity among those who have only seen the lighter cars usually found in that automobilists' centre. In this connection we may mention that the subject of motor haulage is exercising the minds of many local authorities, and the subject has been discussed by the Ashby-de-la-Zouch District Council in a way that should encourage makers to look for development in that district. On the report of the Joint Water Committee Mr. Adcock raised the question for the use of motor-cars for cartage, and mentioned that Mr. Shields had a motor-car running from Breedon Works that had proved very handy and useful. Ultimately it was decided that inquiries into the question of steam haulage should be made, and we hope they will lead to an experiment.

Unequal Justice.

At the Altrincham Petty Sessions a man for furiously driving a cart at the rate of fourteen miles an hour in a crowded street was fined 10s. and costs; at the same court on the same day the driver of a motor-tricycle was fined 40s. and costs for alleged furious driving, although it was admitted that there was nobody about at the time, and yet the latter was said to be driving to the danger of the public. The inconsistencies of our police courts are alarming at times, and surely the driver of a horse in a crowded thoroughfare is far more guilty of offence than the man who drives a motor-vehicle on a country road to the danger of no one. Verily the ways of our police courts are such "that no fellow can understand."

Automobile Excursions.

ONE of the most noticeable signs of the times is the fact that in all the towns along the South Coast motors are now competing with coaches, "cherry-banks," and steamers for the privilege of carrying the visitors round the country sight-seeing. At the present moment the cars are just ordinary ones carrying about five or six passengers. Even at this, however, they show a marked superiority in speed and distance over the best of the horsed vehicles, besides, remarks *To-Day*, being much cheaper to maintain. This testimony from a newspaper that has, in its time, criticised the automobile is reassuring.

Irish Roads.

MR. T. L. STACK, of Tyrone, draws the attention of his neighbours to the bad state of the roads in their locality compared with those of England and many parts of the Continent. He attributes the superiority to the fact that steam rolling has been adopted in all progressive countries. In Ireland it is occasionally met with in Dublin, Kildare, Down, and Antrim, and is under discussion in Fermanagh, but Tyrone, says Mr. Stack, is still "in the Cimmerian darkness of barbarism," so far as steam rolling on the road is concerned. He concludes: "For motor-cars the change is almost essential to their efficient and economical working. We have already one petrol motor in Omagh and others are expected immediately. On good roads motors would soon to a great extent supersede horse traction; outlying villages, such as Drumquin and Gortin, could by steam or perhaps liquid air motors have an efficient transport for goods and passengers with the outer world. Good roads and good vehicular transport, including cycles and motors, would soon develop tourist traffic even in our remoter country districts, which most require assistance by a larger circulation of money to develop trade and employment."

The Watering of Tramways.

THE National Cyclists' Union has taken counsel's opinion as to the legality of tramway companies watering their lines, and they are advised that the excessive watering of tram lines is a nuisance for which tramway authorities have no justification under their Act of Parliament. The National Cyclists' Union are obtaining expert and other evidence upon which they hope very shortly to commence a prosecution. This is a matter of considerable importance to automobilists as well as to cyclists, and the nuisance seems a growing one. Many mishaps have occurred from this cause and it is to be hoped that the proposed action will lead to a mitigation of the evil.

The Use of Gravity.

THE only road users who make an intelligent use of gravity are automobilists and cyclists. A horse and carriage descending a hill are nothing more than a ridiculous spectacle to a person of mechanical perceptions—the steeper the hill the more absurd they appear. Can we wonder, says the *Northern Daily Telegraph*, that prejudice against the motor-car is strong the world over when we see that millions of our fellow

men are quite satisfied to crawl down hill in such a stumbling dangerous fashion? Hills abound, the horse cannot be fitted with a free-wheel clutch, and no one has shown a workable way of putting him on wheels down hill; so it is evident that he is not fit for use on an average high road. Those people who think a motor-car heavy and clumsy should remember that its horse is always on board, and that after propelling the car on the level and up hill it helps it to run down.

Motoring in the North of Scotland.

MR. ROGER WALLACE, Q.C., the Chairman of the Automobile Club, travelled lately from Birmingham to the very north of Scotland on the fast Panhard car of his friend Mr. Bird, of Birmingham, making a swift and delightful journey. In passing through Perthshire they visited the Right Hon. Sir J. H. A. Macdonald, K.C.B. (the Lord Justice-Clerk of Scotland), President of the Scottish Automobile Club, in his summer quarters at Coll-Earn, Auchterarder. The photograph here reproduced was taken in front of Coll-Earn by Mrs. Norman D.

Photo by]

[Mrs. Norman D. Macdonald.

Macdonald, and shows Mr. Bird in charge with his travelling companion beside him. Those who participated in the 1,000-mile Trial will readily recognise the learned judge between his two grandchildren and Mr. Bird's servant. To the extreme left, holding on to the car behind, is Mr. Norman D. Macdonald, chairman of the Scottish Automobile Club, who, as a member of the Scottish Bar, follows the same vocation as Mr. Wallace, and who seems to think he can restrain a 16 h.p. Panhard from running off with his children with one finger. During the visit Mr. Bird enjoyed good sport by flying the large house party in batches up and down the steep hills of the neighbourhood, greatly to their education in motor matters and the astonishment of the natives.

Automobile Club for Nottingham.

THE suggestion having been made by several Nottingham automobilists that the time was sufficiently ripe to justify the formation of a local club for the purpose of developing and protecting the interests of the automobile movement, a preliminary meeting with this object in view has been held at the George Hotel, Nottingham. There were present Messrs. E. W. Wells, G. Cowen, G. H. Kirk, M. Ross Browne, A. King, W. D. Wells, G. Rimington, H. Belcher, H. Rimington, A. H. Niblett, and A. R. Atkey, the last named having convened the meeting. Mr. E. W. Wells was voted to the chair. It was unanimously decided to form an organisation with the name of the Nottingham and District Automobile Club. The meeting also agreed to ask Mr. R. M. Knowles, J.P., to become the first president, whilst

Messrs. G. H. Kirk, E. W. Wells, and G. Cowen were elected vice-presidents. Mr. A. R. Atkey was appointed hon. secretary and treasurer, and a sub-committee was elected to draft rules and to fix upon headquarters.

"Science Siftings" and Motor-Cars.

"CAN'T the rattling of motor-cars be avoided?" is the serious question which *Science Siftings* has set itself to answer. In commenting on its self-imposed question our contemporary remarks that "the buzz and din of the motor-car threatens to become one of the stock worries of life—a state of things which, owing to the easily avoidable character of the nuisance, is much to be deprecated. The practical difficulty of the moment is that we have got into the way of designing and building small machinery after the same fashion as has been arrived at and perfected by the makers of great engines. The circumstances of the two cases are really so distinct that there is no excuse for slavish imitation in the methods of our 'light' engineers." The latter will therefore be interested in learning what the automobile expert of *Science Siftings* considers they should do, and thus he enlightens them:—"Springs, balancing parts and indiarubber buffers ought to be liberally introduced in motor-car mechanism—the high speed reciprocating engine being replaced by an improved slow-speed steady-going affair. Hardly anything, except the cylinder and piston, need be made quite rigid or unyielding. Alternatively—of course the undertaking bristles with alternative ways and means—some new process of consuming benzine might be worked out, adapted to generate a rush of gas and whirl a tiny turbine motor pretty noiselessly." With so many brilliant ideas on motor-car construction the writer of the foregoing should set about designing a car himself. What a contraption it would be!

Voters and Motors.

Now that the elections are over the subject of automobilism and politics is fading in interest; but enough has already been recorded to have justified the prominence which has been given to the matter. On the day of his election for Caithness, Mr. L. Harmsworth drove 160 miles on his car and made several speeches therefrom—a feat that would otherwise have been impossible. At Walthamstow motor-cars were employed to carry Mr. D. J. Morgan to the top of the poll, and on the election day in South Glamorganshire Mr. S. T. Evans, M.P., drove into Bridgend on a motor-car—that being the only incident of interest in that district on the day. In South Bucks, too, Mr. W. H. Grenfell had many motor-cars at his service. During the hearing of a case against Mr. Knights at Chelmsford, it was reported that his absence from court was owing to the fact that he was engaged "carrying voters on motors"—a phrase for which we thank Police Inspector Peters, who thus gives us a title for this paragraph.

The Last Records.

AND now we come to the end of our chronicle of motor-vehicles used for electioneering purposes. In the Farnham and Guildford districts of Surrey motor-cars were plentifully employed on the day of the poll. Dr. Sharpe, of Matlock, lent his Marshall car to his son-in-law, Mr. Briggs, who was the successful candidate in the Keighley division, and who used the vehicle during the whole of his campaign. A week before his election Mr. H. W. Forster, who stood for re-election at Sevenoaks, received a new De Dion voiturette (similar to that supplied by the De Dion-Bouton British and Colonial Syndicate, Limited, to Mr. A. J. Balfour) and used it with immense success in canvassing his constituency. Whereas before he had a coach and two or three teams of horses, he was able during the recent election to cover nearly twice the distance, and with—judging by his majority—considerably more success. On the polling day at Henley Mr. H. H. Fuller covered over a hundred miles on a De Dion voiturette in canvassing that district.

Mr. Frank Morriss supplied a Parisian Daimler car and a Daimler wagonette for use in the North-West Norfolk and Gainsborough constituencies respectively. After the declaration of the poll in the Gainsborough division of Lincolnshire the new M.P., the Hon. S. Ormsby-Gore, mounted his motor-car and addressed the electorate. On Monday a farmer at East Dean, in the Eastbourne division, conveyed his employees in wagons to the polling station. The vehicles were all coupled together and drawn by a traction engine. And with that concludes our list of novelties in the means of locomotion employed in the last general election of the Nineteenth Century.

At Nice.

THE Automobile Club of Nice is more than fortunate in the matter of prizes, for one after another of its members come forward and offer trophies for competition. It is but quite recently that the Count Brunetta d'Usseaux presented a handsome challenge cup to the Club, and now the name of Colonel de Linsky has to be added to the list of generous donors. The Colonel's gift will be put up for a competition by four-wheeled vehicles, weighing less than 300 kilogrammes, and carrying two persons, one of whom must be a member of a recognised automobile club. The race will be contested over a mountainous route of between thirty and fifty kilometres in length, but the exact itinerary has not yet been selected. Evidently there will be no lack of sport in the South of France this winter, for the events already decided upon are numerous, and are of such a character as will assuredly attract racing automobilists. Mention of racing men reminds us that among the recently elected members of the A.C.N. the names of MM. Lorrain Barrow and Gaétan de Méaulne figure, decided acquisitions to the Club's racing contingent. Several automobilists who annually winter in Nice have already arrived, and the number of motor-vehicles to be seen on the Promenade des Anglais is daily increasing. Assuredly the Riviera in general, and Nice in particular, will witness a great automobile season this winter.

A Lady Motorist.

MRS. ALLEN, who contributed so much to the pleasure of the automobilists returning from Lord Llangattock's place last week, is the only lady driver of a motor-car in the Oxfordshire district. The illustration on the opposite page depicts her on the return from a shopping and calling expedition in the university city. In the doorway stands Mr. Allen, who is well known as chairman of the Traction Engine Users' Association—a very powerful organisation of national extent.

Judges' Reports.

WE understand that the Judges' Reports on the trials organised by the Liverpool Self-Propelled Traffic Association are almost out of print. The few remaining copies can be had at 10s. each, and remittances should be sent without delay to Mr. E. Shrapnell Smith, the hon. sec. of the Association. The reports contain much useful data, and should be in the possession of all automobilists who are making up a library of automobile literature.

A NEW company has just been formed at Warren, Ohio, U.S.A. to be known as the Ohio Automobile Company, with a capital of £20,000, to manufacture the Packard petrol car recently illustrated in these columns.

THE Locomobile Company of America, are busy arranging a list of places where their steam-cars can be cared for and repaired in the United States. Already such arrangements have been made in twenty-four different towns.

THE recently formed Associated American Moto-cyclists will shortly hold a club run from Boston to some near-by city. The association does not intend to foster racing, but to protect the rights of motor-cyclists upon the public highway, promote events in the common interest, and cultivate a fraternal spirit among users of this class of motor-vehicle.

MOTOR-VEHICLES AND MOTORS.*

THE probable success of automobiles required that they should have engines of popular fancy in the press; their achievement of success has demanded a permanent tome. They have been the subject of many papers, several pamphlets, and a few books; but all that has been written in the English language falls to a rear position when Mr. Worby Beaumont's ample history is seen. It is a credit to the author, a splendid tribute to the industry, and should be a great factor in the future development of automobilism. Mr. Beaumont is known as something more than a writer on the subject; he is an authority who can speak without notice out of the fulness of his knowledge. When such a man seriously contemplates writing a history, facts, many and authoritative, may be expected. And in such we have not been disappointed.

Mr. Worby Beaumont's volume extends into more than 600 quarto pages, and is illustrated with nearly 500 drawings, most of which have been specially prepared in the author's office, and now appear for the first time. Practically every one of the line engravings will bear inspection with a magnifying glass, and even in the most extreme case of much detail being crowded into a small space the most minute connections will be seen. Thus the book is one that will be extremely valuable, if not indispensable, to engineers and makers of motor-vehicles, while all who take a real interest in the working of automobiles will find its information and explanations complete and exhaustive in every detail.

Commencing with a historical sketch of the motor-carriage, and a capital account of the design, construction, and working of early steam road vehicles, Mr. Beaumont quickly gets into the intermediate period, from 1850 to 1894. The early history is more generally known than that of the years following the prejudicial action of the Legislature, and while making his references to Hancock, Gurney, Dance, and the others comprehensive, he has not lingered on the successes they attained. The chapters on power and frictional losses, road resistances, the resistance due to gravity and power required, and the air and wind resistance, afford evidence of painstaking care, and the data given will save inventors many disappointments and failures. Mr. Beaumont's views on roads are well known, and in the present volume he again draws attention to the question as to whether it is wholly wise to take the roads as they are, and provide power accordingly. This is, of course, necessary under present conditions, but in the opening of the third chapter a different circumstance is hinted at. "So long," the author says, "as our roads are made as they are at present, and as inefficiently maintained, and so long as so many hill-tops are looked upon as the natural and necessary routes over which our roads must be made and every load hauled, so long shall we have to expend many hundreds of thousands of pounds, or even millions,

per year in unnecessary power in horses, and in engines, and in fuel." The point is important, but was so fully dealt with by Mr. Beaumont in his presidential address to the Society of Engineers in 1898 that he has but little more than hinted at the matter in the new work.

Coming to the modern period of automobiles we have valuable chapters on high-speed long-distance petrol motor-vehicles, light petrol motor-cars, petrol motor-cycles, heavy oil motors, electric and steam vehicles. These extend over many pages, and nearly every type of vehicle of every nationality is technically described in a way that will be useful to engineers and owners alike. Carburettors, cylinder cooling and water coolers, motor-vehicle components, electric ignition and electric apparatus, brakes, tires, and steering axles find full treatment in these pages, which are concluded with an excellent article on the uses and cost of working motor-vehicles, and a review of the results of the 1,000-Miles Trial, without which no such volume would be complete.

We propose, on a later occasion, to return to our study of Mr. Beaumont's work, which is well calculated to become a standard volume. Meanwhile praise can be extended to the publishers for the excellent style in which it has been produced, the marginal lettering in red ink being a capital idea. The chapters originally intended to be written by Mr. Dugald Clerk on the physics and economics of internal combustion motors will appear shortly as a separate volume, which will also include a descriptive index to patents relating to motor-vehicles.

MRS. ALLEN—OXFORD'S ONLY LADY AUTOMOBILIST. (See opposite page.)

WE learn that Messrs. Roots and Venables, of Westminster Bridge Road, London, S.E., are at work on a 12-h.p. heavy oil car, in addition to the 3 h.p. and 6 h.p. vehicles at present being turned out.

They also hope to shortly place a new motor-tricycle on the market.

THE presentation of prizes in connection with the Newcastle Coachbuilders' Technical Class took place at the College of Science the other evening. Mr. John Philipson gave a graphic and illustrated lecture on the carriages at the Paris Exhibition.

MR. CARL OPPERMAN, of Wynyatt Street, Clerkenwell, has just put on the market a new sparking coil for use in connection with the electrical ignition of the explosive charge in petrol motors. The features of the new coil, which has been named the "Flambeau," are claimed to be its strength of spark and reliability of ignition; it is said to take less battery power, and is dust and grease proof.

THE International Motor-Car Company, of Great Portland Street, London, W., are busily engaged on the completion of two new types of light motor-cars. Both will have accommodation for three passengers; one will be fitted with a 4-h.p. engine, and will, we understand, be capable of maintaining an average speed on good roads of twenty miles per hour. The second car is intended for an average speed of twenty-seven miles per hour, being fitted with a 6-h.p. motor.

* "Motor-Vehicles and Motors, their Design, Construction, and Working by Steam, Oil, and Electricity. By W. Worby Beaumont, M.I.C.E., M.I.M.E., and M.I.E.E. London: Archibald Constable and Co., Limited. Philadelphia: J. B. Lippincott Co. 1900. 42s. nett.

CORRESPONDENCE.

THE SUGGESTED IRISH MOTOR-CAR TOUR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have only just seen the letter in one of your recent issues on this subject. I sincerely hope the idea will take definite shape. Motoring has made a very good start in Ireland, and such a tour would do an immensity towards developing the pastime. Your correspondent suggests a visit to the manufacturing towns in the north of Ireland. I think this would be a mistake, if motorists desire to bring back a good impression of the country. The roads in the south and west are far better for motoring than in the north, while as regards scenery there is no comparison.

My suggestion would be to run due west and do the circuit of Connemara. Then to proceed round Clare, through Limerick and along the Shannon, to Killarney. The grand coast trip could then be made over a road with perfect surface, through Waterville to Kenmare—thence to Glengariffe, and so through the Pass of Keimaneigh to Cork. From Cork the tourist might proceed to Mallow and follow the Blackwater to Cappoquin, returning to Dublin *via* Waterford and New Ross.

This tour would throughout include the most magnificent scenery, and for the most part really excellent roads. I know these roads intimately, and the greater part of them are up to the English standard.

Such a trip would be a complete novelty to English motorists, bringing them in contact with people who would prove a never-ceasing source of interest to them, and introducing them to scenery absolutely different from anything to be found elsewhere in the United Kingdom.

Dublin, Oct. 10th, 1900.

Yours truly,
R. J. MCCRERY.

THE LAW OF SCOTLAND AND THE LAW OF ENGLAND.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—That the criminal law and procedure of Scotland is superior to that of England has long been recognised by leading English lawyers. But that the law of England, crude though it may be in some of its methods, can permit such extraordinary interference with the liberty and rights of the subject as is shown by the *S. F. Edge*, *A. W. Heard*, and *A. Ford* cases, comes as a revelation to a Scottish advocate. Any magistrate who held that a private carriage *could* "cause an obstruction" would, in Scotland, be very quickly and firmly set right on appeal to the High Court of Justiciary in Edinburgh, with expenses to the wronged party.

Of course, a motor-car or any vehicle plying for hire can cause an obstruction if it does not obey the proper regulations as to stances, etc.; but a private vehicle can only "cause an obstruction" if it infringes any temporary and special regulations made by the Sheriff, or by a Lord Provost (or Provost) and magistrates of a city or burgh, on the occasion of some large gathering or royal procession, etc. But such orders or regulations must be made public and can only apply for a time and to a specified district—they can never over-rule the law of Scotland, which gives full liberty to private vehicles. Of course I can cause a police offence even with a private carriage if I "cause a crowd to collect" by some eccentric conduct, but I cannot be held responsible if a gaping crowd of fools blocks the road to gaze at the common car of the streets; the police should protect me from them, not prosecute me for exercising my daily rights.

As to the case of Mr. Heard at Swansea, any such thing would be impossible in Scotland. Here a man must have due notice of the charge against him and of the date of the trial, and the judge of the High Court of Justiciary, who sits every day in Edinburgh, would at once suspend the conviction in a case like the Heard one till a bench of three or more judges could sit in the High Court on appeals and quash the whole proceedings with expenses. Not only must he have full notice of charge and date, but when the trial comes on he can have the case adjourned so long as is needed for him to get evidence for his defence.

But any such absurd and oppressive methods as are shown in the above cases could hardly ever occur with us, as we have no such objectionable procedure as private or police prosecutions.

Every prosecution in Scotland is by the Crown in the name of "Her Majesty's Advocate" (the Right Hon. the Lord Advocate of Scotland), and by him, or the Solicitor-General, or an Advocate Depute, or a Procurator-Fiscal, all of them trained lawyers under the Crown Office, and doing no other work, and on Government salaries. Under these circumstances there is little chance of foolish, illegal, or vindictive cases being brought into court all. I mention these things not as a lecture on criminal law but to show that many things want seeing to in England, and a clue to where those who agitate for amendment can find a model in this sister Kingdom of Scotland. But surely in that puzzling crowd of Recorders, County Courts, Assizes, Quarter Sessions, Appeal Courts, Queen's Benches, Chancery Courts, Divisional Courts, Courts of Crown Cases Reserved, Divorce Courts, Admiralty Courts, etc., which cause us plain Scotsmen so much amazement, there is some Court which can correct (if it be legal to do so) the eccentric decisions of these "police magistrates and justices."

Yours truly,

NORMAN D. MACDONALD,

Chairman of the Scottish Automobile Club.

Edinburgh, Oct. 15, 1900.

THE WERNER MOTOCYCLETTE.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I was much interested in reading in the *Motor-Car Journal* last week, what Mr. Pennell writes about his tour on a Werner motor-bicycle, because I, too, have ridden one for the last thirteen months, and am quite of his opinion concerning the future of these machines. I have had two of them, having bought the second, a 1900 model, in June last. I had no fault to find with my first, but the extra power of this year's model I heartily appreciate when I come to stiff hills, and it is marvellous how the machine climbs them. I have already ridden my new bicycle about two thousand miles, and that without one single breakdown, having recently crossed Devon and back in one day, up and down the hills for which that county is noted; a ride of 104 miles in six hours, and then not always using the full power available, and riding cautiously. I think that answers pretty clearly the questions of those who wonder whether these machines are practical or not. As regards Mr. Pennell's advice, "you must understand these motors," I concur most heartily, with, perhaps, for choice the "understand" well underlined. Once before I wrote to the *Motor-Car Journal* relating my first experiences, and I fancy I used much the same words. As for burns and blisters, I can safely say that I have had but one little burn up to now; I fancy I must be more wary about touching my motor whilst hot than Mr. Pennell appears to be. Finally, I would strongly, very emphatically, caution riders to on no account go out on greasy roads with smooth tires. The consequences are certain. By all means have non-slipping bands, and even then it is distinctly better not to ride in the mud after all. I have done it and dislike it excessively, with a smooth tire. To use a motor anyone can learn—providing he wishes to do so—all that it is requisite to know, after an hour's riding and explanation, if he can get hold of the right man, one who *does* understand. The French seem to have grasped these facts years ago, and I cannot resist saying here how astonished I am to find such inertia and apparent difficulty of comprehension, such prejudice and futile difficulty-seeking as I have met with whilst discussing the automobile movement with many of my compatriots of all classes.

Yours truly,

A. L. BENETT.

94, Jermyn Street, S.W., October 15, 1900.

THE LUFBERY CAR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I beg to point out that the gear shown on M. Lufbery's car in the last issue of your valuable paper is essentially the same as far as the gear wheels are concerned, as the "Crypto" arrangement. This old and well-tried device dates back to the early days

of the cycle industry, and was patented by Messrs. U. T. Shaw and W. Sydenham on July 7th, 1882, Patent No. 3,230. (See Mr. R. E. Phillips' *Abridgments of Velocipede Specifications*, Vol. I., 1886.) Another gear which also very closely resembles the above French invention is Kirby's patent, No. 5,082, December 6th, 1880 (see Mr. Phillips as above), the combination here being employed as a differential-movement.

Permit me also to point out that the inclined plane for guiding the loose belt from one speed to the other of the cone pulleys is another very old device, and was patented as far back as September 25th, 1877, by Messrs. J. A. Fay, the well-known American manufacturers of wood-working machinery. (See the *Scientific American* for November 10th, 1877, Vol. XXXVII., page 370.) All credit should be given to the French for their smartness and enterprise, but it is not fair to appropriate English inventions without acknowledgment.

Yours truly,
"PRECURSOR."

Cranbrook, October 17th, 1900.

P.S.—The common device adopted by M. Lufbery, as well as many other Continental builders, of obtaining variable speed by an epicyclic train, one member of which is held by a friction band, or its equivalent, is as old as the hills. Besides being a device employed in the early days of the cycle trade, it was introduced by Mr. David Scott, in 1847; for the same end. (See *The Engineer and Machinist's Assistant*, published by Blackie and Son, 1847; also see Mr. Phillips' volume above quoted under the heading of "Two-speed Gears.")

RACING TRACKS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Of course Mr. C. Jarrott has gone for me; but he has not yet gone for the forty miles an hour, and when I hear that an 8-h.p. motor is to be employed instead of one of 6 h.p., I fancy he "recognises" the difficulty of his task—in which I wish him ultimate success. I largely agree with what he says, and accept his explanation as eminently satisfactory. And if I am satisfied he would—did he know my identity—be gratified.

Yours faithfully,

London, E.C., October 16th, 1900.

A B. C.

MESSRS. F. H. PARKYN, Ltd., Olympic Works, Wolverhampton, are the latest recruits to the list of motor manufacturers, they having purchased the stock, plant, and goodwill of the New Courier Company, whose "motoret" they are putting on the market much improved in detail. Of this we hope to be able to give more particulars at an early date.

MR. HANS RENOLD, of Manchester, has just got out a list giving dimensions and prices of the roller chains he is now manufacturing for motor-cycles and cars. The chains are in various widths, and in pitches ranging from $\frac{1}{2}$ in. up to $1\frac{1}{2}$ in. Included in the list is a chain of 1.18 in. pitch specially intended to fit the chain wheels on Benz cars.

THE 1901 models are beginning to make their appearance in France. Early in the field are Messrs. Rochet and Schneider, of Lyons, who announce that they have a new type of car on hand, which will be fitted with a 4-cylinder engine of 12 h.p. The change-speed gear, controlled by a single lever, will be adapted to give four speeds forward and a reverse motion.

AT the Surrey Quarter Sessions at Kingston on Tuesday, Captain Sant, Chief Constable, reported that, notwithstanding warning notices, he continued to receive complaints regarding the furious and reckless driving of motor-cars in the county. Although the police did all in their power to abate the nuisance, they would be unable effectually to deal with it until some system of identification, such as a number, was attached to every car.

THE paper recently read before the Institution of Mechanical Engineers by Professor H. S. Hele-Shaw, of Liverpool, on Road Locomotion and the Recent 1,000-mile Road Trial, together with the discussion thereon, has been reprinted in pamphlet form. The work forms a valuable addition to automobile literature, as the subject is treated in an elaborate way, while the useful diagrams with which it is accompanied add much to its usefulness.

THE LION CONVERTIBLE MOTOR-BICYCLE AND TANDEM TRICYCLE.

WE are able to illustrate this week an ingenious convertible motor machine, which is being put on the market by the Lion Cycle Company, of London Road South, Lowestoft. The first illustration shows the machine in the form of a motor-bicycle. It will be seen that the frame is of special construction, the lower cross tube being curved to admit

FIG. 1. —THE LION MOTOR BICYCLE.

of the motor—a 2 $\frac{1}{4}$ h.p. air-cooled engine of the De Dion type—being fixed within the main frame. The ignition is electrical, while a float-feed carburettor is fitted. From Fig. 1 it will be noticed that the motor is geared to the rear axle by means of two chain drives, the reduction being in the ratio of 7 to 1. No pedal gear is fitted, the low build of the machine enabling the motor to be readily started. Complete the bicycle weighs 140 lbs., and it can, we are informed, attain a speed of forty miles per hour. The novel feature of the machine is the readiness with which it can be converted into a tandem tricycle, capable of accommodating two persons. The change from one type to the other occupies about five minutes, it being only necessary to remove the front wheel of the bicycle and affix the

FIG. 2.—THE LION MOTOR BICYCLE CONVERTED TO TANDEM TRICYCLE.

fore-carriage, which is held in position by six bolts. In the tricycle form the machine is steered from the handle-bar by the rear rider, the same as a motor-quad. The tandem tricycle appears to be a comfortable-looking machine; the makers inform us that it is a good hill-climber, and can attain a speed of thirty miles per hour. The weight of the two seater is 182 lbs., and we may add that the petrol tank has a capacity sufficient for 100 miles. The Lion Company are to be congratulated on having produced what appears to be a practical little vehicle on novel lines. We have not yet had an opportunity of testing its capabilities, but we mean to do so the first time we are in the Lowestoft district.

THE HEAVY MOTOR-VEHICLE COMPETITION IN FRANCE.

(FROM OUR OWN CORRESPONDENT.)

IT was on Monday, the 8th inst., that there commenced at Vincennes, under the direction of M. Forestier, the competition annually organised by the Automobile Club of France, and universally known as "Les Poids Lourds." In common with all the other technical competitions which have this year been held in connection with the Exhibition, these big vehicle trials have quite failed to excite the least interest so far as the general public is concerned, and the daily runs were followed by a mere handful of experts and others directly interested in the question of heavy traction. The wisdom of making this competition an annual one is in itself open to doubt, and on many sides I heard the opinion freely expressed that the A.C.F. would have been better advised to have left it severely alone for this year. Obviously the participation in a trial of this description involves the constructor in heavy expenses, and when the competition is annual one trial is no sooner over than work upon the next year's car must be commenced. When the manufacturer is extremely busy he usually prefers to concentrate his efforts upon the vehicles actually on order, and simply ignores the trial. However excellent and desirable is the advertisement arising from participation in "Les Poids Lourds," the constructor who is full of orders thinks twice before deciding to compete at the sacrifice of his immediate interests. This year one is more than ever struck by the absence of well-known firms, and in the majority of cases their inability to compete is simply occasioned by pressure of current work. If the trials were held every other year I feel convinced that they would gain in interest from every point of view—the entries would be more numerous, the competition keener, and the public would display some degree of interest in the proceedings. For this year's contest the governing regulations were briefly these: Firstly, the competition was an international one, and it was open to self-propelled vehicles constructed in view of the following services:—

1. Public transport in towns; connection between stations and localities with no direct train service.
2. Transport of goods and delivery services.

The cars were required to cover daily a distance of fifty-five kilometres, twenty-two kilometres being the morning's work and thirty-three the afternoon's, both these itineraries starting from and finishing at the Lac Daumesnil, in the Vincennes section of the Exhibition. Neither of these routes was easy, for a large amount of *puvé* and bad macadam had to be negotiated, and in the longer one a couple of ten per cent. grades had to be mounted. The vehicles eligible to compete were: (1) Vehicles carrying at least ten passengers, independent of the driver, with thirty kilogrammes of luggage; (2) Goods vehicles carrying at least one ton under the same conditions; (3) Delivery vehicles transporting a load of at least 1,250 kilogrammes. The competition was based upon the cost of transport—that is to say, upon the proportion between the total running expense of the vehicle and the load carried. No detailed official reports are likely to be published for a considerable time to come, but it is upon this basis of net cost that the judges will make their awards. These awards consist of five *objets d'art*, three silver-gilt medals, three silver medals, and three bronze medals, a fairly liberal distribution among the eleven competitors. All the vehicles were fitted with a speed register, and during the five days' work these showed some 275 kilometres, or 172 miles. Of the thirteen original entries but eleven put in an appearance on the Monday morning, and duly made a start after the usual preliminaries of weighing and verification. These were: Le Blanc, steam tractor towing an omnibus; Panhard and Levassor, one omnibus and one lorry; Turgan and Foy, one omnibus; De Dion and Bouton, twelve-seated omnibus, twenty-seated omnibus, and a lorry; Pantz, one lorry; De Dietrich, one lorry; Say, one electric delivery van; Riker, one electric delivery van. Each of these vehicles was accompanied by an official appointed by the club and a number of military men

who had been deputed by the Minister of War to follow the trials throughout and draw up a report as to the utility of the heavier classes of self-propelled vehicle for military purposes. These officers were not selected from any one arm of the service, but represented the artillery, the engineers, and the infantry, so the report should deal with the practicability of the horseless carriage in relation to the special work of each arm. What the passenger-carrying cars lacked in humanity was made up with sacks of sand, and in due course every vehicle got under way, and in course of time disappeared from view. I drove out from Paris at two o'clock on the afternoon of that day, and at intervals saw the great uncouth lorries steadily performing their work. At the foot of the famous hill at Champigny, well-known to those English motor-men who came over to witness the start for "Le Tour de France," I came across the Le Blanc train and the Turgan-Foy vehicle, both drawn by the road-side and busy revictualling under the scrutiny of the club official and half a dozen officers. We watched the operation to its close, and then followed the vehicles for some little distance, before branching off to continue our longer journey. From that day until Saturday last the cars were put through their daily tasks, and they acquitted themselves well, so far as general running was concerned. Whether their performances were satisfactory from technical and industrial points of view the official reports alone will make known, but it may safely be assumed that some at least have acquitted themselves with distinction. Among the experts who put in an appearance at the trials were three well-known English automobilists, Messrs. Critchley, Baron, and Shrapnell Smith, and a number of leading lights in French automobilism. It is just possible that the actual results will be made known at a comparatively early date, and these I will communicate immediately they are issued. For the detailed report one must wait for a considerable length of time, but this also will, in due course, find its way into the columns of the *Motor-Car Journal*.

ANOTHER addition to the ranks of automobilists is to be found in Sir Charles Forbes, of Stanstead, Essex, who has, we learn, just ordered, though Messrs. Friswell, a Mors phaeton.

THE Thornycroft Steam Waggon Company of America has just been incorporated under New Jersey laws, with a capital of £20,000, to manufacture steam vehicles on the Thornycroft system at Paterson, N.J.

THE RIKER ELECTRIC VEHICLE Co., of Elizabethport, N.J., have recently completed a heavy truck, which is the largest vehicle of the kind that has been built in America. Its carrying capacity is no less than six tons, and a speed can be maintained of two, three, or six miles per hour. The batteries weigh 3,000 pounds, and are capable on each charge of a run of twenty miles on heaviest work. The truck itself, with motors, weighs 7,000 pounds, making a total weight for the vehicle of 10,000 pounds. There are two motors of 10 h.p. each, and each is geared to one of the wheels on the rear axle. The truck is equipped with the Riker flexible running gear. The wheels have 4 in. solid rubber tires. The front wheels are 38 in. in diameter, and the rear wheels are 44 in., all being shod with 4 in. solid rubber tyres.

AUTOMOBILISTS generally will learn with regret of the accident that has befallen Mr. Henry Sturmeý, of Coventry. It appears that Mr. Sturmeý was taking a trip on an experimental car belonging to Messrs. Dawson and Son, motor-car manufacturers, of the ancient cathedral city. Mr. Dawson, sen., was driving, Mr. Sturmeý having a seat by his side, and Mr. Dawson, jun., being behind. When passing the village of Chartham, the driving gear went out of order, and the car turned suddenly round, ran up a bank, through a hedge, and then capsized, throwing the occupants heavily to the ground. The two front riders were seriously injured, and were conveyed to the Kent and Canterbury Hospital. Here, upon examination, it was found that Mr. Sturmeý's left arm was fractured, his left elbow dislocated, and his face considerably bruised and cut. Mr. Dawson, sen., had no bones broken, but was severely shaken. Mr. Dawson, jun., escaped injury.

The Jeantaud Electrical Vehicles.

GENERAL VIEW OF THE SIX-SEATED CHAR-A-BANC.

ONE of the leading builders of electrical cars in France is undoubtedly M. Jeantaud, of Rue de Ponthieu, Paris. In fact, he claims to be a pioneer in electromobiles, he having built a car propelled by means of electricity so long ago as 1881, since which time he has devoted considerable attention to their improvement and popularisation. The handsome vehicles he exhibited at the Agricultural Hall in August, 1898, will still be remembered by visitors to that exhibition, but, fine as they were, they are greatly outclassed by the splendidly-finished cars shown by M. Jeantaud at the Paris Exhibition. These have already been described in our report of the display at the Champs de Mars, but the accompanying illustration of a six-seated electric char-a-banc and a three-seated spider, together with additional particulars, may not be without interest.

In the Jeantaud cars the motor transmission mechanism and batteries are carried on a standard frame of channel steel to which any type of carriage body can be fitted, and when we say that eighteen different types of bodies, ranging from a small two-seated petit-due to an eight-seated omnibus, are being made, it will be evident that there is no lack of choice.

The electromotor employed is of the Postel-Vinay enclosed type—for vehicles weighing complete from 1 to 1½ ton it is of the bipolar type, and for cars above that weight a four-pole motor is employed. The motor is doubly wound, and in normal running absorbs from 25 to 35 ampères of current at a pressure of 80 volts, the speed being 1,600 revolutions per minute. The battery consists of forty-four Fulmen accumulators, enclosed in ebonite cases and arranged in two trays, each carrying twenty-two cells. These trays are concealed in chests arranged in the carriage body fore and aft, and are adapted to be re-charged *en situ*, or to be readily withdrawn for charging purposes. The battery is stated to have a capacity of 60 kilometres (37½ miles), at a maximum speed of 20 kilometres (12½ miles) per hour.

Of special interest is the controller switch employed in the Jeantaud cars; this is adapted to give five speeds forward, a reverse motion and electric brakes. The controller consists of two cylinders—one of them operated by a lever, and carrying five series of contact pieces for changes of speed and reversing,

and the other worked by a pedal, and serving to create resistance for stopping the car, and also for allowing the vehicle to start smoothly and gradually. In the change-speed cylinders the lever can be put in six positions, the first of which cuts the circuit, and the others vary the speed by grouping the batteries in series or in parallel, the highest speed being obtained with the batteries in series, and the motor running as a double shunt. The car can only be reversed by bringing the lever back to the position which cuts the current, and then moving it forward to divide the battery into two parts grouped in parallel and reversing the current in the motor. The second cylinder is operated by a pedal. Two motions are provided; in the first movement the speed is reduced by introducing gradual resistances in the circuit, and the current is finally broken. Continuing the downward movement of the pedal, the motor is put in circuit with a gradually reducing resistance, until a short circuit is obtained, and the car is braked automatically. This is not sufficiently powerful to entirely stop the car on a down grade, and therefore when the pedal brings into action the electrical brake it at the same time operates a hand brake on the motor-shaft. There is also a double-acting band brake operating on each of the hubs of the rear road wheel, and when this is applied the current is automatically cut in the controller. As a further precaution, a third system of brakes works by a screw on the tires of the rear wheels. The motor is geared by pinions to a differential counter shaft, from which the power is transmitted to the rear road wheels by the usual duplicate set of sprocket wheels and chains.

Steering is controlled by a horizontal hand wheel, actuating the front wheels, which are mounted on the Jeantaud-Ackermann system. Usually wooden wheels with bronze hubs are employed, but cycle-type wheels can be fitted if desired, while the tires are either pneumatic or solid rubber. Both volt and ampère-meters are fitted in full view of the driver, and at night these are illuminated by means of a small electric lamp.

DR. R. J. HEATLY, of Stockwell Road, S.W., would be glad to hear the experience of those who have used steam motor-cars.

SOME MOTORING EXPERIENCES.

BY THE HON. LEOPOLD CANNING.

LONDON to Manchester and back is a long and wearisome journey by rail, but nevertheless, I did this the other day, for the purpose of seeing what progress was being made on the motor-vehicle being built for me by the Century Motor Company, of Altrincham. On arriving at the works, which are large, I was introduced to an extremely busy scene. A great deal of work was being done, and a goodly number of men were most actively engaged in working the machinery. Several handsome Century motor tandems were to be seen at one end of the premises. I cannot understand why people buy air-cooled quadricycles when, for a very little more money, they can have a Century motor tandem, with a complete water-cooled motor up to 4½-h.p., pump and radiator, a friction clutch with change of gear, and a beautiful front seat, luxuriously upholstered and hung on C springs. The manager of the works, Mr. A. M. Heard (the Company have works also at Willesden Junction), whose courtesy could not have been surpassed, showed me round. I was specially pleased with the wheels of my machine; they are 30 inch, and all the spokes had been turned, and not drawn out in the usual way. This will give them greatly increased strength. The hubs are of extra strengthened gun-metal. My motor engine, which is of 5 h.p., was being prepared, though not yet ready for work.

I have a Longuemare carburettor, but am doubtful of having this fitted, in view of the fact that Mr. Jackson, the foreman of the Century Company, has invented a new carburettor, which the company claims to be superior to any other make. As I did not hesitate to express my doubts that there should be anything superior to the Longuemare, they proceeded to give me a proof of what their carburettor could do with bad petrol.

There was a De Dion voiturette on the premises, which had been brought in fifteen days before and never touched since. This voiturette was fitted with their carburettor, which still contained some of the same petrol which had been there a fortnight ago. The foreman went up to the car, and at the first turn of the starting handle the motor was set in motion, and at once went off at a furious rate. After that conclusive proof of what their carburettor could do I thought I would discard my Longuemare. The friction clutch they have invented is also a wonderful thing. Leather or fibre is entirely dispensed with, only metal being used. This saves one much trouble; there is no adjusting to be done and no leather to be often replaced. I found it to work extremely well in action.

I was taken out on a 4½ h.p. Century for a trial run. The road near the works for about half a mile was nearly 2in. deep in mud. I expected the back wheel would be certain to skid, but never once did this happen, going fast or slow, uphill or down dale, and even when swinging round corners. What is more, my driver asked me to look at our tracks behind, through the mud, and there they were, absolutely straight, through that slime. When we got out to the country, I took the steering lever in hand. Though I had never been on a Century motor tandem before, or even seen such an original system of steering, in two minutes I had advanced the sparking to full, and was steering the machine at over forty miles an hour with perfect ease and confidence.

This one ride at forty miles an hour on a more or less lonely country road, with hardly a soul in sight, resulted in two different summonses from the police. One of them was satisfactorily arranged, but the other ended in a fine of £2 with 22s. costs. At no time whatever did we endanger the lives of the public, as we mostly had the road to ourselves, and if a carriage did turn up we immediately slowed down to a crawl. However, all that went for nothing, of course. We saw four policemen, who all looked very hard at us. Needless to say we were carefully doing no more than the legal speed while they were in sight, but it was no good. Once when the engineer was driving, and we were moving at a modest little thirty-five miles an hour, the motor suddenly slowed down to a crawl, and on my inquiring what was the matter I was informed that he had just spotted a policeman peering over a hedge.

I think the way the police behave in these country places is disgusting! They are like beasts of prey, who conceal themselves in a well-chosen lair, from which they can jump out and pounce on their unfortunate victims. It is a new form of highway robbery. The policeman does not actually empty your pockets on the road, but you have to turn out your pockets later on because of him, so it comes to the same thing. At one moment a group of men upon the road concealed a policeman, for, as we came by, he rose out of the middle of them and scowled at us.

On the way home, I experienced the first little unpleasantness I have had in three years' motoring, and this was the first motor run I have had in England, except one or two short rides in London. We were coming up to a farmhouse where a knot of men stood with some horses and carts by the side of the road. They were, all big, hulking ruffians, and as we approached them a burly fellow stepped on to the road and picked up a big stone. This he hurled at us with all his might as we went by, but thanks to our forty miles an hour it just missed us. If it had struck either the machine or ourselves it would have done considerable damage, and had there not been so many of them we should have stopped for a little talk with them, but six were too many for us two to handle.

In France I always carry a revolver with me, and there I would probably have fired at the man for his pains, but such a thing has never happened to me there. My mother was once riding in her Panhard on a lonely country road in France. She had no one with her except her *mécanicien*, who ~~was~~ driving. On turning a corner they were confronted by a horse-drawn vehicle, in which were seated two fearful-looking fellows, who resolutely barred the way. They were apparently bent on mischief, and, following up a volley of abuse, one of them seized an enormous pole which they had, and was on the point of dealing the *mécanicien* a fearful blow, when Lady Garvagh pluckily drew her revolver and coolly levelled it at the villain in question. Seeing she had a very steady aim, and looked mighty like pulling the trigger, they hastened to get out of the way, and to cease from obstructing the further progress of the motor-car.

Apart from the little unpleasantness that befel me, I most thoroughly enjoyed my ride on the Century. The motor pulled splendidly, there was no question as regards its capability in speed, and we took all the hills well on the high gear, never having to resort to the lower.

Needless to say, I am looking forward immensely to the day on which my machine will be completed, and I am also sending the company my 4 h.p. Aster tricycle to convert into a Century motor tandem, as I am so pleased with the working, steering, and running of the latter. The day on which I was there two lucky owners of recently completed machines came and took them away. I offered one of them, cash down on the spot, a little more than what he had paid for his machine if he would hand it over to me. Here was an opportunity of having more than his money back, in case there was the slightest dissatisfaction in his mind; but, oh, dear no! I might have doubled my offer at that time without success.

THE driver of a motor-car, named William Gunning, was fined 10s. at Barry last week for driving along the highway with only one light.

THE Sports Motor-Car Company, of 113, Fulham Road, South Kensington, S.W., have arranged to issue, free of charge, an insurance policy against loss or damage by fire to all purchasers of Mayfair voiturettes.

THE youngest licensed automobile driver in the world is now claimed by Chicago. He is Chauncey B. Blair, son of the president of the Merchants' National Bank. Young Blair, who is fourteen years old, received his licence on September 21st.

IN connection with the Automobile Club's commemorative run to Southsea on Saturday, November 10th, the Motor Car Company, Ltd., of Shaftesbury Avenue, W.C., are arranging to run several passenger-cars, returning from Southsea on the following Monday. The fare is, we understand, three guineas return per passenger, the box seats being one guinea extra.

HERE AND THERE.

MAJOR R. E. CROMPTON, R.E., sailed from Capetown in the ss. Saxon on the 3rd, and is expected home on the 20th inst. Hearty welcomes await him from members of the Automobile Club and other organisations of which he is a leading light.

ONE of the neatest pieces of rhyming in connection with automobilism I have yet seen comes from Mr. Henry Edmunds, a well-known member of the Automobile Club, and is as follows:—

You may ride on a horse, or a mule, or a moke,
You may drive in a carriage, or sail in a boat,
You may swim in the water, or fly in the air,
Go just as you like, but only take care,
You may skate, you may walk, take train, tram, or bus,
Go in great state, or without any fuss,
You may bike on a wheel, a single or tandem,
Go just as you please, at will or at random,
You may stay at home near, or travel afar,
But nothing can equal a mote on a car.

A MOTORIST may evidently indulge in poetry with safety and credit, but when a poet takes to motoring I will not be responsible for the consequences, unless, like Mr. Rudyard Kipling, he adds other qualities to his versifying talents.

IN the *Morning Post* a gentleman has been suggesting that the motor-car should be provided with some species of "cow-catcher"—an idea which occurred to him after a "hairbreadth 'scape from a Juggernaut motor-car." I have heard of a petrol car, an electric vehicle and a steam carriage, but the "Juggernaut motor-car" is probably an Indian variety of automobile with which I am not acquainted. Possibly it is a cross between a steam roller and an elephant; enlightenment will be welcome. It would have been a pity had the dog been killed, and evidently the animal was of an intelligent kind. All lovers of dogs are great admirers of the automobile, for it is developing in the canine tribe the organ of curiosity and the acuteness of the London newspaper lad, who dodges horses' heads with wonderful skill. The other day I was on a car, when a lovely little poodle that looked like a rolled up door-mat came snarling along. He ran right under the car—being careful to avoid the wheels—and came out at the rear. Then he retraced his steps and peeped from the front with a pleasant bark, as though he enjoyed the fun. So persistent and so agile were his antics that we had at last to dismount and drive him away. The incident proved that when the dogs are kindly disposed no hurt will come to them. But when they let their temper get the better of them, look out for remains.

WHILE the cavalcade of motor-cars was proceeding from Monmouth to Tintern the other day a dog made unpleasant barking and ran amuck among the cars. He was laid low and flat. As much depends on the disposition of the canine as on the proximity of the car—a copy-book heading that should be placed over every kennel.

THE other week I recorded an election incident which told against the motor-car for electioneering purposes, and in a certain Kentish constituency one political party declined to have anything to do with such novelties. Judging from something that occurred in the case of a Scotch member seeking re-election they were wise, for the candidate drove up in his motor-car some ten minutes late for a meeting and began speaking practically before the machine had ceased to snort. A workman in the audience enthusiastically declared to the men standing near, "You see he brings his platform along with him." "Yes," rejoined his neighbour, "his platform was always a movable one." As a means of getting about, the automobile is admirable; but as a political machine it is execrable, from one point of view. And, of course, the point of view is everything.

IN the Chesterfield division of Derby even worse things befel Mr. T. Bayley who sought, and obtained, re-election. On the day before the poll two motor-cars arrived in the town to

assist in conveying voters to and from polling stations on the morrow in Mr. Bayley's interest. The men in charge of the cars put up for the night at the Angel Hotel, and placed their machines in the care of the landlord. At an early hour the next morning, when the *mechaniciens* went to their machines for the purpose of cleaning them, they discovered that a very important part of the steering apparatus had been removed from each machine and taken away. Various bolts and screws had also been loosened. It was at once apparent that a plot had been perpetrated to render the cars useless for the purpose for which they had been imported. A reward of £20 was offered at once for information that would lead to the discovery of the thief, and information is in possession of Mr. Bayley's supporters which in all likelihood will lead to the proper punishment of the miscreant. One of the motor-cars was rendered useless for the greater part of the day, and the other, though temporarily repaired, was rendered somewhat unsafe. Even motor-cars are not wholly secure from mishap on election days.

ON Tuesday the Queen created the Rt. Hon. J. H. A. Macdonald a K.C.B. This honour to one so enamoured of automobilism will please his friends on both sides of the Tweed. His many interests are revealed in his full title, which is now Brigadier-General the Rt. Hon. Sir J. H. A. Macdonald, K.C.B., LL.D., F.R.S.S. (L. and E.), M.I.E.E., Lord Justice-Clerk of Scotland, commanding Forth Brigade, and Adjutant-General of Her Majesty's Royal Bodyguard.

THE fifth session of the Liverpool Self-Propelled Traffic Association will be opened on the evening of Monday, December 3rd, at the Royal Institution, Liverpool, by M. G. Forestier, Inspector-General of Roads and Bridges in France, President of the Technical Commission of the Automobile Club of France. The title of the address is "Heavy Motor Traffic in France," and it will be illustrated by both lantern and cinematograph views.

MR. REYNOLDS, who drove the Peugeot voiturette referred to in last week's account of the Automobile Club's invasion of Monmouth, intended to take the vehicle back to India with him. He is about to return, but the voiturette will not go to our great dependency until various repairs have been made.

BETWEEN Eastbourne and Brighton is Pevensey, an old-world sort of place with some interesting ancient houses, a wonderful old castle, and the identical bay in which the name of Julius Cæsar is associated in the bygone history of our land. One of the more modern places there is Harold Lodge, a pleasant resort for trippers and cyclists, which stands in close proximity to the castle, and has storage for motor-cars. This is a feature of increasing importance to such establishments, and I shall be glad to hear of similar establishments along the south coast, where motorists are regarded with kindly concern.

MR. J. J. MANN is back again in town, after a short visit to Paris. He tells me that the Marshall car upon which he made the 1000-mile Trial is going splendidly, and has done quite 5,000 miles of travel since that event. The new landau is likely to prove a good winter car, being easily convertible and very comfortable, two essential features in such a climate as our own. The medical profession are still keenly solicitous with regard to the Marshall cars, Dr. Pratt, of Bletchingley, being one of the latest purchasers. During the recent heavy floods in the Lake district one of these cars was being taken to a purchaser at Cockermouth. At Kendal some parts of the town resembled a swimming bath, and the only shelter for the car during the night was a disused barn in which it was placed. In the morning it was standing up to the engine in water, but on being fished out and overhauled was driven off and got safely to Cockermouth. A 6 h.p. car is in contemplation, and when it is ready I hope to have a pleasant trip thereon.

LOLLIUS.

WE hear that the Wolseley Sheep Shearing Machine Co., Ltd., of Birmingham, are engaged on the construction of a new type of two-seated voiturette, which they hope to put on the market early next year. The car will be fitted with a motor of 3½ h.p.

A GERMAN MILITARY TRANSPORT MOTOR-WAGON.

IN a recent issue we gave illustrations of several types of motor-vehicles that have been adopted by the military authorities in France. On the present occasion we are able to publish an illustration of a German military transport wagon which has lately been built by the Berlin Motorfahrzeug-fabrik Gesellschaft of Marienfelde, Berlin. The vehicle forms part of an order placed by the German Naval Union with the Marienfelde concern and the Allgemeine Electricitäts Gesellschaft of Berlin, jointly, for two complete portable wireless telegraphy outfits for use in China in connection with the Boxer troubles in the Far East. The original order called for two motor-vehicles, but as only twelve days were allowed for delivery it was not found possible to finish two cars in the time. Consequently one apparatus is fitted in the motor transport wagon herewith illustrated, and the other in an ordinary closed wagon. The motor is a six-horse-power one, using petrol as fuel, and besides furnishing the motive power for the wagon, also drives the dynamo for supplying electricity to the telegraphic apparatus. It will be seen from the illustration that as regards

the transmission gear of the vehicles this closely follows the lines adopted in the German Daimler cars.

The second wagon is equipped with a battery of accumulators, a small dynamo, a 2 h.p. high-speed petrol motor, the latter having been completed by the Marienfelde Company in twelve days. For supporting the vertical receiving wire, balloons capable of holding one-half of a cubic metre of gas are employed. As the motor transport wagon will also be required to serve as a field telegraph apparatus, it is provided with spools of telegraph wire supplied by Messrs. Siemens and Halske, of Berlin.

A LICENCE to store a ton of petrol within easy reach of their premises in Trent Street, Nottingham, has been secured by Messrs. A. R. Atkey and Company, Ltd.

MESSRS. DE DION, BOUTON AND COMPANY have now brought out a 2½ h.p. motor, fitted with a water-cooled combustion head, the set including a water tank with connections, and also a radiator.

MR. C. OLIVER ISELIN, a gentleman well known in American yachting circles, has taken to the motor-vehicle, and has just returned to the United States from a tour of two thousand miles and more through France.

THE Committee on Superintendence and Police of the Fairmount Park Commission, in Philadelphia, has decided to admit automobiles to all Park drives except the West River drive between Girard Avenue Bridge and the Falls of Schuylkill, and the Wissahickon drive. The former is desired for a speedway for drivers and the latter is too narrow. No automobile will be allowed in the Park after October 15, unless it is plainly numbered.

MOTOR-CARS ON THE CONTINENT.

A New Insulation.

It is reported in a Russian journal that a Mr. A. M. Imschenetzky is about to form a company at St. Petersburg for the purpose of exploiting a new insulating substance which he has invented, and which he styles "Uralite." Asbestos, chalk, and silicate are the predominating elements of this new preparation, and it is said that neither excessive cold nor heat has any effect upon it. It is capable of being readily worked, and is a bad conductor of electricity, heat, and sound. Acids do not depreciate it, and it is unaffected by sudden changes of temperature. If this new preparation possesses all the good qualities claimed for it, the Russian company should speedily work up an extensive and profitable business, for such a material would be invaluable for a thousand and one purposes. Further news will be awaited with interest.

A Record by Demester.

THE famous track of the Parc des Princes, Paris, continues to be patronised by considerable numbers of racing cyclists, and last week the well-known *chauffeur* Demester made a couple of attacks upon the records existing for one hour and 100 kilomètres, but in neither case did he realise his object, owing to the peevishness of his motor. What he did succeed in doing, however, was to beat the record for one lap, made by Rigal some few weeks ago. The exact distance is 666 mètres, and Demester's time, made from a flying start, was 31½ secs., equivalent to a speed of about seventy-seven kilomètres an hour. This is the fastest recorded speed on the track, but it is morally certain that during Rigal's trials of September 25th last he covered some laps faster than this, for his times for one kilomètre and one mile represent a greater speed per hour than does that made by Demester. The limit of speed has been practically reached upon the Parc des Princes track, and to travel faster, racing men will have to search for another enclosure more steeply banked.

The Chanteloup Hill-Climbing Contest.

THE annual race up the hill of Chanteloup, which in former years was organised by *La France Automobile* will this autumn take place under the auspices of the Moto Club. The selected date is Sunday, November 4th, and important modifications of the original regulations have been decided upon. Two categories only are provided, and racing vehicles, at any rate in racing gear, will be left out in the cold. The first class is for cars exceeding 400 kilogrammes in weight and carrying at least four persons seated in a proper body. Vehicles weighing less than 400 kilogrammes and carrying two persons will be admitted to the second category. These restrictions destroy much of the racing character of the event, and in a corresponding degree the amount of interest taken in it by the public. The people do not want to see climbing a hill the class of vehicle they can see every day on the road. They wish to have a look at the powerful racers flying the up-grade at sixty kilomètres an hour and unless this is to be witnessed, people will not trouble to journey out from Paris to Chanteloup. Of course, the organisers have no choice in the matter, for it is not likely that the authorities would accord permission for a genuine race, and therefore the event must of necessity be reserved for those vehicles which cannot break the country's laws, at any rate on an up-grade of 10 per cent.

Accidents in France.

THE horse: 106 deaths, 918 wounded—total, 1,024; the railway: 25 deaths, 49 wounded—total, 74; the bicycle: 9 deaths, 137 wounded—total, 146; the automobile: 2 deaths, 27 wounded—total, 29. Such is the summary of *Le Vélo's* statistical table of accidents which occurred in France during the month of August last, and a glance at it reveals the increase of mishaps occasioned by the noble beast during the period dealt with. In bringing about 1,024 accidents he has fairly excelled

himself, and the performances of the other means of transport, that standing to the automobile in particular, sink into absolute insignificance beside these figures. Of the two deaths lying to the charge of the automobile, one is rendered particularly regrettable by reason of the cowardly conduct of the driver, who, after knocking down and killing a farmer of the Gironde Department, drove off as speedily as possible. Accidents will occur, but when they do the least that the automobilist can do is to render all possible assistance, and not to run away from his responsibilities as the driver at Cerons and only too many others have done.

The Berlin Track.

MENTION has already been made in these columns of the intention of the German Automobile Club to organise a series of automobile races on the Notting track of Charlottenburg-Westend, situated at some five miles from Berlin, and I am now able to add that after a number of trials the organisers are of opinion that the track will be practicable for these "courses" without any material alterations. The track measures about one mile in length, and so satisfied is the Club with the experimental runs that it has been decided definitely to hold the first meets in the spring of 1901. Motor-cycles, light and heavy cars will all be provided for, so hurry up, racing men, and see that your machines for next year are already in hand.

The Auto-Velo.

THE Administrative Council of the Automobile Club of France has just issued a circular letter informing members of the creation of a new journal, styled the *Auto-Velo*, which will be devoted to the automobile industry in general, and the club in particular. This publication will be issued daily, and its *redaction* will be composed of the leading authorities on all matters pertaining to automobilism, both from an industrial and sportive point of view. Not the slightest suspicion of any political question will be permitted to appear in its columns. In making this announcement the club committee add that being persuaded that this organ will render the greatest services to the society in keeping its member *au courant* with every movement of the automobile world they have decided to forward it gratuitously to every member of the club. I understand that the Baron de Zuylen, Count de Dion and Count de Chasseloup-Laubat, as well as other members of the A.C.F. committee, have seats on the board of directors of the new publication. This move by the club is not surprising, for the work done by the society is now but little noticed by the *Velo*, and members are often quite ignorant of current events. In the columns of this latter paper one reads but of the doings of the Moto Club, and under such conditions it was imperative that the A.C.F. should have an organ of its own.

THE "Stéate" sparking plug illustrated in our issue of March 30th last is now being put on the English market, Mr. P. Dailly, of 12, Hart Street, Bloomsbury, W.C., having secured the agency for them in this country.

M. OUTHENIN CHALANDRE, of Paris, is just now making a display of De Dion voitures at Messrs. Hall and Sons, coach-builders, 97 and 98, Long Acre, W.C. Included in the vehicles exhibited is a handsome little car with a four-seated *tonneau* body.

WE learn that Mr. Dan Albone, of Biggleswade, has just completed a new type of car—a landaulette, to carry five persons. The motor is of the tandem type of 8 h.p. No water-circulating pump is employed, and the water is cooled by means of funnels catching the air and carrying it through the water tanks, which are of large capacity. Wheel-steering is fitted.

WE have received a pamphlet from Mr. E. T. Scammell, of 37, St. Mary Axe, E.C., descriptive of the Bingham road paving system. The paving, which is a combination of stone and wood, was invented by Colonel John E. Bingham, of Sheffield, in 1895. The advantages claimed for it are:—(1) safety; (2) durability; (3) cheapness; (4) cleanliness; and (5) quietness.

THE CREST SPARKING PLUG.

THE Crest Manufacturing Company, of Cambridgeport, Mass., U.S.A., have recently introduced a new sparking plug which is claimed to be unaffected by heat and expansion, and to be unbreakable. After considerable experiments with the best porcelains of foreign manufacture they claim to have discovered, through the assistance of a well-known chemist, a new material that is unbreakable by heat or expansion. It is well known that the sparking plug is a delicate piece of mechanism and gives considerable trouble, and for this reason motorists are compelled to carry one or two spare sparking plugs in their kit. The plug, of which illustrations are given herewith,

consists of a shell of steel having a thread at one end to screw in the orifice of the chamber of the motor. The sparking plug proper consists of a slight cone of this new material, which is inserted in the steel plug. This cone fits tight in the shell, making a gas-tight joint, without packing. Through this cone a wire is passed, terminating at the bottom of the plug with an enlarged head. A platinum wire is inserted in the body of the steel, the spark jumping across between the two points.

MESSRS. MOELLER AND CONDRUP, of 78, Fore Street, E.C., have sent us a list of the Swedish spanners, oil-cans, and brazing lamps for which they are agents.

A SCOTTE steam road train has just been put in service at Pau, France, for the conveyance of both passengers and goods.

SOME experiments with an electric service wagon are being carried out by the fire brigade authorities at Schaerbeek, near Brussels.

WHAT will be the first motor-car in Adelaide, South Australia, has left England this week. It is a Deschamps Victoria, and is being taken over by Mr. F. Gordon Ayers.

WE have received a copy of a new American weekly, *The Motor World*. Judging from the first number, it should quickly take a prominent position among the several automobile publications in the United States.

SOME farmers in the neighbourhood of the suburban house of Mr. A. C. Bostwick, the well-known American *chauffeur*, having complained of that gentleman's motor-vehicle as a dangerous innovation, he has offered to make a bet that he can bring his car, going at fifteen miles an hour, to a dead stop as soon as a horse and wagon going ten.

M. PAUL MEYAN, well known in French automobile circles, is the first *chauffeur* to mount the heights of Aution, near Antibes, in a motor-car, over a bad road, 86 kilomètres long, rising 2,080 mètres above the level of the sea. His arrival astonished the engineer officer in charge of the fort. It is considered that the performance may lead to the adoption of automobiles for communication with the military posts in the Alpes-Maritimes.

ON Monday, at Darlington Borough Police Court, Jacob Dunn, of Morton Palms, was charged with driving a horse and trap without lights on August 25th. The evidence of F. W. Sewell was that he was riding a motor-tricycle on the day named at nine o'clock at night, between Darlington and Fighting Cocks, when he ran into defendant's trap. It was without lights. The defence was that the conveyance was standing when complainant ran into it, and under the bye-laws lights were not then required. On this point the Bench dismissed the case.

MOTORS AND MOTOR-CARS: THEIR DEFECTS AND REMEDIES.*

IT is not proposed to go into the historical part of the subject, but it may be mentioned that a machine was constructed by Mr. Edward Butler in London between the years 1884-1886, at the same time as Messrs. Benz and Daimler were at work in Germany. The machine, which was called the petrol cycle, was very much like the Bollée machine afterwards brought out, and was not further developed because of the "Red Flag Act," which did not allow its use in this country. At the same time Mr. Butler also constructed a high speed oil motor or engine to run from 800 to about 1,000 revolutions per minute. At this time there were no gas or oil engines which would run above 180 to 200 revolutions.

Lenoir engines, both single and double acting, were made in large numbers, and extensively used; but they were too extravagant in gas, renewals, and repairs; though had Baron Roche's patent specification been known and read, the engines could have all been converted for a few pounds, instead of being consigned to the scrap heap, and Otto's patent would have been anticipated. The Otto system is too well known to need description.

Motor-cars cannot take their supply of gas from the street mains very well, so a portable gas works, or "carburettor," is carried, in which air, during the suction stroke of the motor, is drawn through or over a volatile spirit called petrol or gasoline, having a specific gravity of .680 to .700. What is a carburettor? or what kind of carburettor should be used? many people enquire, especially those who have a thirst for motor philosophy. The carburettor is a vessel in which a small quantity of petrol or hydrocarbon is carried and mixed with air in a regulated quantity to suit the motor. Firstly, the air can be drawn across the liquid; secondly, the liquid can be sprayed through a vessel; thirdly, the air can be drawn across a saturated cotton or gauze wick; or, fourthly, the oil can be injected into the motor direct at each suction stroke. The suction of the motor causes the gas to be generated when wanted, in sufficient quantities to supply the motor and effect complete combustion without smell. Carburettors may be divided into the following classes:—Firstly, surface carburettors; secondly, spray carburettors; thirdly, wick carburettors; fourthly, petrol ejected, with air supply, direct. There are many carburettors. Some are very good, and some are very bad. Some of them work the best of the spirit off first, leaving the stale to get home with; which is very bad, the carburettor giving no gas, and, consequently, the motor no power. It is like feeding a horse with good corn for the outward journey and giving him dust and straw for the return.

Lubrication is a most important point in connection with the successful working of motors. Gas or explosion engines would have been possible years before the days of Lenoir, Otto, and others, had someone come forward with a mineral oil to lubricate it with. The heat of the explosion, the temperature of which is about 800 to 1,000 degrees Fahr., should pass through the walls of the cylinder, after every power stroke, to the water jacket. The temperature of the cooling water ought not to exceed 180 degrees Fahr., or else the oil will become congealed in the motor cylinder. Cylinders that are fitted with heat radiating ribs are not worth discussing. These cylinders get so hot that the pistons stick after working a short time. The cylinders themselves also become distorted, the valves stick up, and various other troubles present themselves, which have led the author to the conclusion that even for small motors a water jacket is required to get the full power of the motor, and to get rid of the offensive smells of unjacketed motors.

Some men have clipped or threaded radiating ribs on to their cylinders. Now to get the thorough effect of radiating, there must be a continuity of substance. Heat will not pass through separate bodies as through a solid one. Motor cylinders require a well-finished bore, and a fairly fitted piston with rings well ground into the cylinders. The rings should be tongued at the joints,

which should be held at equal distances from each other. In this respect, what will do for a steam engine practically will not do for gas or petrol engines. A still further improvement may be looked for in this respect. A compression of over 100 lbs., or more if it could be maintained, would be the means of increasing the power of the motors considerably.

The exhaust valve must be water-jacketed and kept as cool as possible, otherwise it will get too hot and scale; also it will become distorted and stick up, and release the compression so that the engine will lose all its power and stop. Great attention should be paid to the valves to see that they are seated properly, and they should be ground in with rotten stone, not emery. It does not much matter whether the seats are mitred or flat. The valves and valve seats should be made renewable, and separable from the motor, so that spare ones can inter-change, as the fault is not always with the valves themselves, but with the valve seatings, which are usually made a part of the motor. The same pattern of valve could serve both for the inlet and the exhaust, and in the case of a double engine one pattern of valve may serve for both cylinders. Instead of lift valves, Mr. Butler still uses a revolving valve that travels at half the speed of the motor. The author has seen these valves taken out after working for a month day and night—resting only on Sundays. The valve is similar to a Corliss valve, revolving instead of reciprocating. A black oxide forms on the wearing part of the valve or seat, which makes it almost impossible to touch with a file. As these valves have now been running successfully for about fourteen years, they are worth the attention of motor constructors. The valve springs in use on most motors are far too short, and ought to be longer. Valves, pistons, and rings should be thoroughly cleansed in paraffin, and the crank shaft turned round some forty revolutions when the motor is not in use. This would largely prevent the sticking up of valves, tight pistons, etc.

A motor-car engine should be constructed as light as possible, without any signs of springing or contortion, remembering the force of the explosion acting on the piston, say at 600 or more revolutions per minute. The moving parts also should be as light as possible, and balanced. As far as the piston, connecting rod, and crank go, the fly-wheel may be suitably weighted, and should be as large as possible, and heavy. Even then a large amount of vibration will exist, especially when the car is stationary, and the motor is running as slowly as possible. The vibration is not felt when the car is travelling slowly, and, to my mind, is more imaginary than real. The motor-car is for travelling purposes, not for standing still at corners to shake up its passengers. If motor men must stay at corners, let them stop their motors and then start them again when required. To get rid of this so-called difficulty, motors are made with two or more cylinders, arranged in different ways to partially balance themselves. Not only do the moving parts require balancing, but the explosions also. Firstly, take a double-cylinder motor, with the cranks set opposite one another. Here all the moving parts are balanced, but not the explosions, and there is an impulse at every one-and-a-half revolution. Secondly, take a double-cylinder engine, cranks set together. Here we have motor parts unbalanced—impulse or explosions every revolution. Explosions or impulses are more regular, but not balanced. Thirdly, take a single-cylinder engine, with piston and cranks, as usual, instead of a back cover, another piston having a cross head with two connecting rods, one at either side, coupled on to cranks set together opposite to the centre crank, so that the pistons meet and recede from one another at each revolution. This, in the author's opinion, is a very rude practical attempt at balancing. The side connecting rods can never be made to work without knocking, and that even at slow speeds. Fourthly, take a single cylinder, open at both ends, with two pistons, each piston connected with a rocking beam, and each rocker connected to a single crank by the connecting rod; here there is perfect balancing of parts and explosions, but at the expense of increasing the number and weight of moving parts. Fifthly, take a single-cylinder engine of the simplest construction, and the moving parts made as light as possible, heavy fly-wheel balanced for its intended speed, moving parts which are partially balanced by the

* Abstract of paper read by Mr. Chas. T. Crowden before the Cycle Engineers' Institute, Coventry, October 10, 1900.

fly-wheel and balance-weight. The centre of the fly-wheel should be placed in the centre of the car, and revolve in the direction in which the car travels. All these so-called balanced engines have been made and tried, and as they were more complicated to keep up and more expensive to manufacture, and not suitable for running at high speeds, the author considers for a motor-car a one-cylinder engine, with simple parts, get-at-able on the road, far more useful than these complications.

The oil or petrol motor, unlike the steam engine, cannot be readily started and stopped, and therefore must be kept running whether the carriage is at rest or going full speed. A governor is usually fitted to control the working number of revolutions. Other means for slowing down the number of revolutions when not required are sometimes fitted. With the use of steam the motor can readily be started and stopped, as long as sufficient steam can be supplied from the boiler or steam generator. With the petrol motor a friction clutch, a transmission gear, and a change speed gear are required. With the steam engine, instead of the foregoing, a troublesome steam generator is required, with its cleaning of tubes internally and externally, which ought to be

cars are driven by means of belts and pulleys. Some of these are fitted with fast and loose pulleys; in others, the belts are tightened by means of jockey-pulleys when it is required to drive. This makes an excellent arrangement for light cars, and is far easier to keep adjusted than the friction clutch and gearing. If a belt slips it can be taken up on the road, but to repair the teeth of cog-wheels means a long job only to be done at home. And, again, the belt and pulley gear dispenses with the necessity of a friction clutch or clutches.

The road carriage or truck should be constructed much stronger than for horse draught to do the same work, as it must be remembered that the horse is carried as well as the load, and that the driving strain of the horse is to be taken up by the carriage. The wheels must be stronger, as they have not only to carry the load, but to drive it along as well. The tires should be elastic; solid rubbers tires are the best known at present. Pneumatics are far too expensive, and on some roads very dangerous. The vehicle should be fitted with a strong and well-constructed steering gear, and with a band brake, operated by a foot lever, acting on the differential gear shaft. There should also

THE JEANTAUD ELECTRICAL SPIDER. (For description see page 555).

done every week. In the case of steam motors, water and fuel can be carried to last from twenty-five to thirty miles running. Oil fuel is too expensive in this country, but it is very convenient, as the heat can be easily regulated to make the necessary steam required to drive the motor over the various roads to be traversed.

Most motor manufacturers put their engines anywhere convenient—many in one corner of the frame, some in front, and some behind. The motor should revolve in the direction the carriage is travelling; and if one fly-wheel be used, this should be placed on the centre line of the car; if two fly-wheels are used, one each side of the centre line. Motors arranged in this way will steady the carriage whilst travelling and will minimise the vibration and prevent it from capsizing. Fly-wheels placed horizontally will give even better results. Most makers fix their motors too near the ground, so that they are difficult to adjust and repair, being more or less in the dust and dirt. Motion is transmitted from the petrol or continuous running motor by means of a friction clutch or change speed gear. For driving a differential countershaft or axle by means of chains or spur gearing, at least three or four changes should be provided. To change the speed-gear wheels it is first necessary to withdraw the friction clutch, then make the change in the gear, and lastly put the friction clutch slowly in again. Other

be a powerful lever brake acting on both hind wheels as an emergency brake. A device should be fitted for preventing the car from running back downhill in case the motor should fail. The body should allow access to all the machinery, so that it can be adjusted and examined without removal. For examination at home, the body should be easily removable, without disturbing any levers or machinery of any kind. The author would urge the necessity of using the very best material and workmanship in the construction of motor-vehicles. Inferior and cheap materials are useless. To work motor-cars successfully, especially petrol engines, cleanliness is the great secret of good running. Stoppages, or so-called breakdowns, are in nine cases out of ten due to negligence, forgetfulness, or dirtiness on the part of the operator, and it is by serving a course of failures and trials, which are disappointing at the time, that one becomes sufficiently wise to prevent the same occurring again in the future. A discussion followed the reading of the paper, in which Messrs. Sturme, Staner, Hewitt, Warner Jones, Craig, and Leechman took part.

THE Aberdeen District Motor Service Company has started a service from Market Street, Aberdeen, to Ferryhill. The cars run at fifteen minutes' interval.

FURIOUS DRIVING CASES.

T. ROWLAND OUTHWAITE, manager of the Edinburgh Autocar Company, was, at Edinburgh Police-court last week, fined £5, with the option of twenty days' imprisonment, for having, on September 10th, in Bruntsfield Place, ridden a motor-tricycle in a furious and reckless manner.

At the West Powder Petty Sessions, recently, George B. Ibbetson and John Cann, mining students, Camborne, were summoned for driving a motor-tricycle at a greater rate than 14 miles an hour, and to the danger of the public. Superintendent Bassett said that of late complaints had been received about defendants driving their motors at a furious rate from Truro to Camborne, and that several horses had been frightened. Sergeant Jeffery said that on the previous Sunday afternoon he heard the machines coming through Chacewater, and on leaving the village they covered a furlong he had previously measured in 18secs., or at a rate of 25 miles an hour. Ibbetson admitted they might have gone a short distance at a good speed in order to get an impetus to mount Killifreth Hill. The machines had powerful brakes, and could be pulled up in less than half the distance required to pull up a horse and trap. Defendants were each fined 10s. and 9s. costs.

At Altrincham, last week, Ralph Jackson was summoned for furiously driving a motor-tricycle on the highway at Rostherne on September 28th to the danger of passengers. Police constable Scott deposed that the defendant was going at the rate of twenty-five miles an hour at least. Defendant explained he was trying a new motor. At Bucklow Hill they went at a fair speed, but there was no one on the road. He was under the impression that if there was no one on the road he would not be endangering life. He had ridden 18,000 mile without accident. The chairman said the bench were unanimous in their decision that it was a most dangerous thing for these motor-cycles to go along the road at that rate. Defendant would be fined 40s., and costs 22s. 6d.

At Dorking, a few days ago, Percy Dodson, of London, was fined £2 for furiously driving a motor-car at Capel on the 12th ult. P.S. Wytherly said he was near Wigmere when defendant passed him on a motor-car at a terrific pace. Witness shouted to him to stop but he took no notice. He then timed him from that spot to Holmwood station—a distance of a mile, which he covered in about two minutes, showing he was going thirty miles an hour. Eventually witness traced defendant to London.—Defendant said the motor was a slow one, and for that reason he was bringing it back from Mr. Barnett's, at Rudgwick, who had refused it.

At the Thorne Petty Sessions, last week, Ernest J. Steel was summoned for furiously driving a motor-car at Langtoft, on September 28th. P.C. Briggs stated that on the day in question the defendant passed him on the road from Market Deeping. He gave no notice of his approach, and went past him like a train. He estimated that he was travelling at twenty-five miles an hour. This evidence was corroborated by P.C. Williams, J. E. Gout, and W. Senescal. The Court fined the defendant £3, and costs 15s. 6d.

CYCLIST v. MOTORIST.

IN the Wandsworth County Court on Monday, Mr. William Bullock, of Twickenham, sued Paris Singer, Ltd., for damages. The plaintiff's case was that as he was cycling on the Portsmouth Road, accompanied by a lady friend, he was startled by the shriek of a siren close behind. Ere he could get out of the way a motor-car dashed into him, throwing him with great force. According to Paris Singer Co., Ltd., the lady and gentleman were on the wrong side of the road, and, alarmed by the siren's warning, collided with each other, and fell in endeavouring to get out of the way. Judgment for £18 and costs was, however, awarded the cyclist.

ALLEGED NEGLIGENT DRIVING OF A MOTOR-CAR.

At the Wimborne County Court on Friday last week, before his Honour Judge Philbrick, Q.C., Mrs. Blanche Llewellyn, of Tarrant Keyneston, sued Mr. W. R. Warn, of High Street, Poole, for damage sustained to a trap caused through the alleged negligence of the defendant on July 23rd, whilst driving a motor-car between Wimborne and Broadstone. Mr. W. J. Raymond, solicitor, Wimborne, appeared for the plaintiff, and Mr. H. T. Trevanion, solicitor, Bournemouth, was for the defendant. The plaintiff stated that on July 23rd she was driving a cob in a two-wheel dog-cart from Wimborne to Broadstone. She saw the motor-car coming towards her, and as the horse became restive, she held up her hand as a sign to the driver to stop the car. At the time she was a good distance off—more than a hundred yards, and there was plenty of time for the motor-car to be pulled up. As she approached nearer the car her horse became still more restive, and she held up her hand again, and also shouted to the driver. Her horse was so very restive that she got out and went to the horse's head, but it backed and shied at the car, and the shaft knocked her in the side, causing her to fall in the bank. The horse upset the trap, turned round, and made a bolt. The trap was damaged considerably, and had cost £5 to be repaired. The motor-car had stopped when the horse turned round. If the defendant had stopped the car when she first held up her hand she should have passed all right. Mr. Trevanion said no one could regret more than his client that the accident

occurred, but the question was whether he was to blame. Defendant was acting strictly within his rights, and was a most experienced and careful driver. The plaintiff, Mr. Trevanion submitted, did not give an intelligent signal, or the motor-car would have been stopped before. Mr. Warn, the defendant, said that he had had experience in the driving of light locomotive cars for three years. On the day in question he was driving his mother to Wimborne, and the hill where the plaintiff met him was the steepest gradient along the road. The hill was a quarter of a mile or more in length, and he sighted the two ladies in the trap when they were at the top of the hill. He was going up the hill very steadily. When he was nearing the plaintiff and had got partly up the hill he reduced the speed of the car to eight miles an hour and then to four, and at that time the ladies got out of the trap. The plaintiff led the horse on and patted it, and then halted, and he naturally thought that she wanted him to pass. He saw immediately afterwards the horse's ears go up. He expected what was coming, and stopped. He was right in close to his near side. He had never seen anything to lead him to suppose that the lady wanted him to stop. Several witnesses were called, and his Honour observed that the evidence seemed overwhelmingly in favour of the defendant. All the witnesses were clear in their statements that both the trap and the motor-car were stationary before the accident, the car being thirty yards away from the horse when it bolted. It appeared to him that the horse did not bolt from being frightening with the motor-car at all, but through the unfortunate meddling by the plaintiff with the reins. That seemed to him to have been the cause of the accident. Therefore there appeared to him to have been no breach of the regulations by the defendant. He must, therefore, give judgment for the defendant.

The Midland Motor Agency have, we learn, removed from Acock's Green to Ladywood-road, Birmingham, where they have opened a motor repairing depôt with accommodation for the storage and cleaning of cars.

QUITE a number of cars are now to be seen regularly in the streets of Wolverhampton. Several residents now possess them; a Daimler private omnibus, a Benz car, a De Dion quad and a tricycle with trailer, together with the Star Company's cars and the Sunbeam car of John Marston, Ltd., being frequently met with.

A METHOD for temporarily repairing external punctures in pneumatic tires has been devised by M. Esmond Francois, of Paris. The device, which is known as the Indispensable Bracelet, consists of a piece of leather, treated with rubber, and provided with straps, which can be fixed around the tire over the damaged part.

THE partnership subsisting between William Henry Stevens and George William Burnell, carrying on business as cycle and motor-car makers, at Lower Brook Street, Rugeley, Staff., under the style of Stevens and Burnell, has been dissolved. Mr. G. W. Burnell, by whom the business will in future be carried on, keeps a stock of motor-car spirit and is well equipped to undertake repairs to motor-cars and cycles.

MR. ALBERT C. BOSTWICK, who recently returned to America from Europe with a powerful French car, is reported to have covered a mile with the vehicle in 1min. 27.45sec., at the tri-State fair in Guttenburg, New Jersey, a few days ago. In the open race for petrol vehicles Mr. Bostwick covered five miles in 7min. 43.15sec., which beats the record by Mr. W. K. Vanderbilt, jun., of 8min. 53.4secs., made in Newport, by more than a minute. In the ten mile race, Mr. Bostwick gave a still more wonderful exhibition, covering the distance in 15min. 9.15sec. From the third mile on all the miles were covered in less than 1min. 30sec.

A MOWING and reaping machine fitted with a petrol engine, by which it is driven without aid from horses, is exhibited at the Vincennes Annex of the Paris Exhibition by the McCormick Harvester Machine Company of Chicago. The motor is a double-cylinder 10 h.p. petrol engine of American design. The power from the motor is transmitted by an endless chain to a sprocket wheel and friction clutch placed on the cross-shaft of the mower. This clutch is so arranged as to engage either one bevel-gear wheel or another placed on each side, and in this way the machine can be made to advance or go backward at will. The speed of the motor can be increased or diminished while the machine is at work by simply changing the regulating lever. Steering is effected by a crank placed within easy access of the operator, and connected below by a steel bar direct to the guide wheel, which is in front of the cutter bar.

THE Motor-Car Journal.

COMMENTS.

MOTOR-CARRIAGE 1118

IN addition to the particulars published last week with regard to the Automobile Club's trip to Southsea, we would add that motor-vehicles may be stored in the Drill Hall of 1st Hampshire Royal Engineer Volunteers on production of tickets to be obtained from the Club. Petroleum spirit will be obtainable in Southsea from Messrs. S. Rose and Co., 43, Castle Road, Southsea. The following list of repairers on the route will be useful in case of breakdowns, which, we hope, will be as few as usual on Club runs:—Godalming, C. Rutherford, High Street; Guildford, F. Ostler, Bridge Street; Kingston, Prestwich and Burt, River Front; Petersfield, Roswell's Cycle Works; Portsea, J. Tout, 1A, Queen Street; Southsea, S. Rose and Co., 43, Castle Road, and J. R. Penning, 6, Elm Grove; Winchester, Gandy and Sons, 25, Parchment Street, and Dean and Smith, Upper Brook Street. It is gratifying to learn that the number of entries—a full list of which we propose to publish next week—is very large.

Steady Running.

It is hoped that drivers on the occasion of this run will bear in mind that it is important in the interests of the movement that they should employ only very moderate speeds, especially in passing through towns, approaching cross-roads, etc. The object of the tour is to demonstrate the advance of automobilism in this country and to impress people with the advantages and pleasures connected with it. A harum-scarum race from London to Southsea would do far more harm than good. There is good reason to believe that the police in the neighbourhood of Kingston, and indeed as far as Godalming, will be especially active on this occasion. Furthermore, the Chief Constable of Southsea has intimated unofficially that if motor-vehicles travel at a speed higher than eight miles per hour they will undoubtedly be summoned.

Moderation and Care.

SHOULD any such summonses result from a Club run the effect would not be pleasant. So far the tours have been characterised by moderation and care on the part of all participants, and there is no fear as to the exercise of the same virtues on the forthcoming occasion. At the same time, we give the warning, as there will be several non-members taking part in the affair who may be unaware of the stringent rule of the Club in this respect. There is no doubt that the committee of the Club is extremely anxious to prevent any illegal driving on the road, and that the members generally recognise their duty.

A Cup for Clean Vehicles.

IN connection with the anniversary run to Southsea Mr. A. Harmsworth, a member of the Automobile Club, has offered a £5 cup for the motor-vehicle which, in the opinion of the judges, to be appointed locally, may on its arrival on Southsea Common be the most presentable as regards cleanliness and general appearance. Mr. Harmsworth is of opinion that the public become prejudiced against automobiles by seeing them arrive in towns smothered in dust and looking generally disreputable, and that automobile drivers would do well to show pride in the appearance of their carriage, and to remove the dust and other stains of travel from themselves and their vehicles before entering towns.

Accident to Mr. Mark Mayhew.

JUST too late to be included in our last issue came the news of the accident to Mr. Mark Mayhew, L.C.C., the well-known motorist. It appears that Mr. Mayhew was proceeding home along the High Street, Wandsworth, late on Wednesday of last week, and had just crossed the Wandle Bridge, when the car—a Renault voiturette—skidded. The vehicle mounted the pavement, the collision with the kerb causing Mr. Mayhew to be thrown out on his head. Assistance was soon at hand, and Mr. Mayhew was conveyed to Dr. Badcock's, of East Hill. Here it was found that Mr. Mayhew had a nasty cut over the eye; but, although much shaken by the accident, he had fortunately escaped serious injury. After having the cut attended to Mr. Mayhew proceeded home in a cab. We are pleased to be able to report that he has almost recovered from the effects of the accident; in fact, on Friday of last week he was out for a spin on his new 16 h.p. Napier car. The Renault voiturette was much damaged, two of the wheels being broken, an axle bent and the steering gear deranged. It was taken to the works of the Comet Cycle and Motor Company, Wandsworth, where the necessary repairs are being carried out. Since the above was written we have received a letter from Mr. Mayhew, in which he attributes the accident not to a skid as we surmised, but to the fact that he must have gone over a brick, which turned the car out of its course. As Mr. Mayhew points out, the steering of the little Renault car is of the bicycle order and easily deflected, and having only one hand on the handle bar at the time of meeting the obstruction, he could not recover before the car was on the pavement. The vehicle, however, did not overturn, as was stated in several of the daily papers.

An Abandoned Contest.

THE promised excitement of a race between a horse and a motor-car up Porlock Hill has been abandoned—to the keen regret of all sportsmen. It appears that Captain Jay has parted with the horse upon which he had intended to make the ascent, and the present owner is disinclined to put the animal

to such a test. Mr. Mark Mayhew is not particularly anxious to risk his own safety and that of his fine new car—which is giving splendid results—on the dangerous gradient of Porlock Hill. Probably it is as well for both the horse and the motorist that the match has been abandoned.

Roads in London.

THE condition of the roads in London has long been a disgrace. They seem to have been at the mercy of a dozen and one authorities, who have apparently conceived it as part of their duty to disturb the roads as soon as possible after they have been "made up." One day a nice stretch of wood pavement, smoothly laid, may be seen, and then, a few hours later, what a change! In the meantime, the workmen of a gas company have probably come along and, having settled on a "claim," have "pegged it out," and proceeded to chip up the wood blocks in a delightful and leisurely manner. Having dug up a foot of earth they replace it and put wood chips loose on the top. There is then a lovely mound for the irritation of those who travel along that way. A few weeks later sewer, water, or other mains are attacked, and so the game is continued from one year to another. Even new roads are thus ruthlessly ruined and made dangerous for all classes of traffic. This state of things—so inimical to the proper regulation of our streets—must be stopped. If only on the score of economy to the ratepayers no interference to the roads must be allowed, except at certain seasons of the year, and then only by special permission of the Councils.

Conditions which should be imposed.

OF course there may be exceptional circumstances, but these should be rare indeed. Because a householder does not pay his gas bill, a company should not have the liberty to take up the centre of the roadway and inflict inconvenience upon the users of the road. The welfare of the whole community must not be subordinated in the shameful way that has been so apparent in Metropolitan thoroughfares of late. Should special conditions arise, such as burst pipes, etc., permission to deal with the roadway ought only to be given on the understanding that the work be proceeded with day and night. The road should then be relaid to the satisfaction of the surveyor. Officials and councillors will have to do their duty in this matter; the policy of *laissez faire* must come to an end, and that very quickly.

Mr. Cordingley a Candidate.

HOLDING so strongly to these views as we do, our readers will not be surprised to learn that Mr. Charles Cordingley is a candidate for the new borough council of Holborn. He is standing in the North St. Giles ward as an Independent candidate, and will be glad of the help of readers who have leisure next Thursday, and who can assist with their motor-vehicles in taking voters to the poll. We shall be glad to hear from any such owners as early as possible.

The English Motor Club.

ON Saturday last, about twenty members of the English Motor Club participated in a pleasant run to Brighton. In the party were Messrs. Jarrott, Napier, Barnes, G. H. Smith, M. Moyle, T. Maltby, Cecil Edge, Arthur Goodwin, and F. R. Goodwin. A splendid trip was much enjoyed, and on Sunday the members of the party made their way back to town at their own sweet will. In thus promoting sociability among motorists the Club has been doing a useful work.

An Interesting Fete.

IN connection with the Paris Exhibition, an interesting fête is to be held on the 31st inst. The "Fête of Means of Locomotion," as it is called, will bring together, besides the most up-to-date automobiles, the vehicles of yesterday and of the near and remote past. Roman and Gallic chariots, possibly

not altogether authentic, but at all events faithfully reconstructed, will head the procession. Some of the finest specimens of old gala coaches and beautifully decorated sedan chairs, shown in the "Centennial Exhibition of Carriage-building," will come next, with ancient diligences and the first Paris omnibus. Finally, the procession will be closed by the latest types in motor-cars. Each vehicle will carry passengers attired in appropriate costume, from Roman charioteers to modern whips, and from powdered marquises of the Regency to the French lady motorist of to-day in full motoring costume.

London to Paris.

LAST week we gave the portrait of Sir J. H. A. Macdonald, K.C.B., and in the present issue we are favoured with an interesting article from his pen descriptive of his trip between the English and French capitals on Dr. Dawson Turner's car. The excursion seems to have been a very pleasant one, marred only by the wearying monotony of the sound of "teuf, teuf," to which the Lord Justice-Clerk of Scotland has great aversion.

Motor-Omnibus for Newport.

MR. C. D. PHILLIPS has made an offer to the Newport (Mon.) Corporation to run a motor-omnibus from the tramway terminus in Commercial Road to the pier-head of the Alexandra Dock, provided the Corporation assent and grant him the requisite licence. The Lighting and Traffic Committee of the Corporation has informed Mr. Phillips, in reply, that they see no objection to the scheme, and it is, therefore, expected that the new service (the necessity for which has long been felt) will shortly be started. Mr. Phillips states that the car will seat twenty persons. He is now away from Newport making, as is supposed, a purchase of the most suitable car. The extension of motor-omnibuses to the outlying districts not yet served by the tramway system is, it is hoped, heralded by this excellent departure. There is also a good field for enterprise in a service from Dock Street to the docks.

Heavy Haulage in the City.

THE motor-wagon of the Val de Travers Asphalte Company has been the cause of a driver in the employment of that concern appearing in the City of London Summons Court. The driver said the pace was not more than four miles an hour; therefore it was unnecessary that the brakesman should be on the van, especially as he was available to apply the brake if necessary. Despite these facts a fine was imposed, and the letter as well as the spirit of the law will have to be observed in the City in future.

Motor-Cars for Military Purposes.

ON another page we refer once more to the attention which is being paid by military authorities on the Continent to the question of utilising motor-cars for transport and other purposes. For a long time we have been hammering away at the question with the view of causing our own military authorities to take an active interest in the matter, and, as recently recorded in these columns, there is now some hope of this taking place. We are glad to see the *United Service Gazette* among those who recognise the importance and urgency of the subject of the utilisation of the motor-car in military operations. Our contemporary in a recent issue remarks: Presumably our War Office is kept well informed both of what has already been done in foreign armies in the way of employment of automobiles for military purposes, and also of the details of the more extended use of them which is contemplated. But are the reports of these things merely pigeon-holed in the recesses of the Intelligence Department, or are they studied with the attention they deserve by those responsible that our army shall not lag behind in the carrying out of any ideas tending to promote its efficiency as a fighting machine? In the present development of automobilism the employment of auto-

mobiles for all these purposes may not be practicable or advantageous. But it is very certain that the motor has come to stay. What it cannot do to-day it may accomplish to-morrow.

Pennington's War Torpedo.

EARLY visitors to Richmond Park lately have been startled by seeing a motor-car travelling at an unusually fast pace. Enquiries have resulted in ascertaining the fact that it is Mr. Pennington's motor war torpedo. The vehicle has a very "uncanny" appearance, its four wheels being shod with 5½-inch pneumatic tires. The main frame is of steel tubing; the machine is propelled by a two-cylinder motor, the cylinders being 5½-inch diameter by 12 inch stroke, coupled to a central vertical fly wheel, the power being transmitted from the crank shaft to the rear or driving axle by two chains. There is the usual differential gear, and the usual gears for hill-climbing. The machine is designed to be covered with an armoured case and to have rapid-fire guns mounted for war purposes. The armoured shield and the guns will be detachable, so that the machine can be used without them. Some wonderful accounts are current of the speed of the vehicle, one correspondent putting it at between sixty and seventy miles per hour!

The Auto-Velo's Maiden Race.

THE new French daily sporting paper, the *Auto-Velo*, has quickly got to work and has already commenced the organisation of its first course. This event will take place on Thursday, November 8th, and the rules governing it present distinctly novel features. First of all, the competitors will be divided into six classes, these being:—1. Cars weighing more than 1,000 kilogrammes; 2. Cars weighing from 700 to 1,000 kilogrammes; 3. Cars weighing from 400 to 700 kilogrammes; 4. Voiturettes weighing from 250 to 400 kilogrammes; 5. Voiturettes weighing less than 250 kilogrammes; 6. Motor-cycles of several seats. These cars will be required to make an average of from fifteen kilometres as a minimum, to thirty kilometres per hour as a maximum, over the Suresnes-Meulan route. They will be handed a certain quantity of petrol at the point of departure, and will not be permitted to renew that supply *en route*. Upon returning to Suresnes—if they get there at all—the competitors will continue to run round the racecourse at Long-champs until their supply of petrol is exhausted. Certificates will be issued, stating that such and such a vehicle, weighing so much, ran a certain distance at a given average speed upon a certain quantity of petrol. The supply awarded to each category is as follows:—1. 20 litres; 2. 16 litres; 3. 12 litres; 4. 9 litres; 5. 7 litres; 6. 6 litres, and once poured into the tank this will be closed and sealed. The cars will be weighed absolutely empty, that is to say, without water, petrol, or lubricating oil. The French Automobile Club is putting up a medal for the winner in each category, and already upwards of twenty entries have been received.

Facilities for Charging Electrical Vehicles.

MR. PERCY STILL, chief engineer of the Chelsea Electricity Supply Company, Ltd., has written to the Automobile Club stating that his company are considering the question of providing facilities in Chelsea for storing and charging the batteries of electric motor-cars. He states that they could make such arrangements if there is a probability that advantage would be taken of them to a reasonable extent. Before deciding upon the terms on which they could provide suitable space and electric current for this purpose the company would like to have some information as to the amount of current and the pressure which is usually required, the average time occupied in charging, between what hours of the day attendance should be provided at the charging dépôt for admitting motor-cars and looking after

the arrangements. Probably motorists and others interested in electrical vehicles will communicate their ideas on the subject to Mr. Still.

A Paris-Berlin Race.

THE long-talked-of race between Paris and Berlin was definitely decided upon at a meeting of the committee of the French Automobile Club last week. It was originally intended that a Paris to St. Petersburg automobile event should take place next year, but difficulties in the way of the undertaking have compelled enthusiastic supporters of the proposed Franco-Russian contest to abandon the idea for the present. Berlin has, accordingly, been chosen instead as the goal of the chief international automobile race next year. The event is to be arranged by the Automobile Club of France, in conjunction with the Automobile Club of Germany. It is stated that the German Emperor is taking a great interest in the proposal, and Count de Talleyrand-Périgord, vice-president of the Deutsche Automobil Club, announced at the meeting of the committee of the Automobile Club of France that his Majesty intends giving £2,000 in prizes for the contest. The distance by road from Paris to Berlin is 775 miles. The date of the race has not yet been fixed, but it will take place either at the end of May or the beginning of June next.

SPEEDING ALONG—A REMINISCENCE OF SUMMER.

Motor-Cars in Australia.

A CONTEST, unique in the history of Australia, took place at the Royal Agricultural Show in Melbourne on September 6th last, when a De Dion voiturette, recently imported by a local merchant, was entered for competition against the Thomson steam phaeton, a vehicle built in the colony. Three tricycles were also entered, but did not compete for the special gold medal offered by the Thomson Motor Car, Limited, to stimulate interest in the industry. The judges, although not experts in motor-cars, were experienced carriage builders, and decided to judge the two vehicles on the broadest grounds possible. The result was, therefore, a most interesting contest, both vehicles making good time on the track. Carrying loads, starting, stopping, steering, etc., etc., were also successfully performed by both vehicles, and the judges eventually gave the award to the Thomson steam phaeton, on the grounds of its greater suitability to the Australian market, that it uses kerosene instead of gasoline, and its ease in management. The award carried with it the special gold medal, the first prize and silver medal presented by the Society, and it is gratifying, writes our Melbourne correspondent, to find that the locally-made car could more than hold its own against such an up-to-date vehicle as the De Dion voiturette.

Wise Surveyors.

SEVERAL road surveyors in Cheshire are anticipating events. Instead of leaving their repairing until there is a likelihood of frost interfering with it, they have already got their men to work.

A fair amount of new metal has been laid and rolled in the Wilmslow and Alderley districts, and as the good work is still in progress on the highway between those places it behoves night-riders to travel cautiously. It is to be hoped that the Wilmslow authorities intend to tackle the slope from the foot of the station approach to the railway bridge. The macadam, which is only half-way across the road, has sunk below the level of the setts. Some of the setts themselves are in a bad way. This is also true of many other districts, and is one of those matters in which automobilists should make their combined influence felt.

Activity of the Police.

ALREADY the opponents of the motor-car in Norfolk are gloating over the activity of the police in consequence of recent speeches of county councillors and others. On Saturday, Lord Cranworth presided over the Norfolk Quarter Sessions, when the report of the Standing Joint Committee referred to the fact that instructions had been issued to the Chief-constable to apprehend all persons who travelled at an excessive speed in motor-cars. Lord Cranworth took occasion to refer to this, remarking that already the instructions issued had borne fruit, two prosecutions having taken place at Thetford, while another was pending at Yarmouth. And all the roads round about are not busy thoroughfares. That between Norwich and Thetford is usually deserted, and the journey by motor-car can generally be made without meeting a solitary pedestrian or vehicle.

Look out in Surrey!

MOTORISTS driving in Surrey must really be careful, for Captain Sant, the chief constable of the county, is applying for the sanction of the Standing Joint Committee for a general increase in the police force to deal with the automobilists who are alleged to drive furiously along the roads. Having read the county journals very carefully of late we have little doubt the increase will be granted, for there is everywhere a great deal of prejudice against motorists. Hence our warning.

A Recorder Speaks Strongly.

MR. A. R. KINGLAKE, the Recorder, in his charge to the grand jury at Bournemouth Quarter Sessions on Tuesday, made some strong comments on the excessive speed of motor-cars. He said that rules and regulations could be made by county councils, but they had to be certified by the Local Government Board, and all the answer they received from that Board was that the matter was being considered. Something ought to be done to protect the public from the risks they always ran when out with horses and carriages. What good was it for a policeman, even on a bicycle going twelve miles an hour, to try to catch motor-cars going twice as fast? It was impossible. Nor could policemen certify to gentlemen in leather jerkin and green goggles seen by them on the highway travelling at a rapid pace. People who owned motor-cars ought to have the maximum rates for fines, and if they repeated an offence it should be considered how they should be dealt with. Certainly!

Educating Councillors.

As a corrective to the arrant nonsense talked by many councillors on local authorities with regard to the speed and control of motor-vehicles, the Automobile Club intends to invite the members of councils that have to consider the question to take trips on automobiles and so lessen their horror of modern vehicles. The idea is not a new one; but it is worth the adoption of individual owners throughout the country, and we

shall be glad to hear from any owners who have been able to give trips to members of local boards, with a view of removing erroneous ideas with regard to motor-cars.

A Novel Electrical Vehicle.

At the invitation of the Geo. D. Moffat Company we journeyed to the Thames Embankment on Monday afternoon last to inspect a new type of electrical carriage which has been on view for some days at the Burlington Carriage Show Rooms, Oxford Street, W. All the electric vehicles so far designed have employed one or two motors whose power is transmitted by external gearing to but two road wheels, and in which both motors and gearing are more or less exposed. To overcome these features and obtain the greatest possible traction with high efficiency, the hub motor system has been devised. The system, which has been brought out in America by the Hub Motor Company, of Chicago, differs from all others in that a motor is placed in each hub of the wheels instead of suspending one or two motors from the axle and body. Each wheel so equipped becomes a driving wheel, giving the entire possible traction, and enables the machine to get rapidly under way when power is applied. A compact double reduction gear is encased in the hub so as to be water and dust proof, and while under usual conditions the entire equipment is in service, if an accident should occur to one or any three of the motors, they could be separately cut out and the machine operated on the remaining one. The car exhibited on Monday, which was in charge of Mr. C. Ledwinka, one of the inventors, took the form of a light two-seated vehicle carried on a tubular frame, but instead of all the four wheels being provided with hub motors only the rear pair were so fitted. The battery is placed underneath the seats and consists of forty-eight cells with a capacity of eighty-five ampère-hours, sufficient for a run of fifty miles. The battery weighs 560 lbs., and the carriage complete about 958 lbs. The wheels, which are of the wooden type, are shod with pneumatic tires. The hubs measure ten and a half inches exterior diameter, and the contained motors are said to develop normally $1\frac{1}{4}$ h p. each.

Some of its Features.

As above mentioned, the vehicle exhibited was only fitted with two hub motors, but it was pointed out that the car was only brought over to show the construction of the hub motor, and certainly the absence of any motor or transmission gear was most noticeable; the only thing unusual about the car being the relatively large size of the hubs of the wheels, to which, no doubt, we should soon become accustomed. One point which is claimed to be a great advantage is that the motors can be operated nearer the rated capacity on level roads than others, for the combined horse power can be less since the four points of contact allow better traction when muddy roads or heavy grades are met with. When bad roads or hills are encountered the four points of contact are said to allow the vehicle to run on less power than if only one set of wheels were equipped, and hence the statement is made that the total horse power can be less. It is stated that in regard to repairs the equipment is compact in each hub, and the gears cannot be thrown out of mesh and rattle as is the case when long pinion shafts are used to transmit the power to a gear on the vehicle wheel. The wheel with its enclosed mechanism can be removed in a very few moments and another unit or an ordinary carriage wheel substituted. Thus in case of a break down the whole vehicle is not laid up for repairs but only one or two hubs, as the case may be. We could not ascertain on Monday whether it is intended to place small electrical cars with hub motors of this type on the English market; but we learn that a syndicate has been formed to acquire, through Messrs. Shippy Bros., the rights in the hub motor system as applied to omnibuses and heavy vehicles, and that orders have been placed for two buses, one to seat 40 and the other 30 passengers. The larger of these is intended to run between Kilburn and the Marble Arch and the other between Liverpool Street and Brompton.

Motor-Cars for Military Purposes.

Cliché de]

FIG. 1.—A SCOTTE STEAM TRACTOR HAULING A SIEGE GUN.

[L'Acqui-de l'Automobile.

EVER since the commencement of the publication of the *Motor-Car Journal* considerable prominence has been given to the question of the utilisation of the motor-car for military purposes, and it is with satisfaction that we notice that the *United Service Gazette* has taken up the subject. In a recent issue our contemporary remarks that during this year's autumn manoeuvres on the Continent automobiles have been employed to an extent which is probably very imperfectly realised in England. In nearly every foreign army they have been

on the first day of the exercises overturned a distinguished general and his staff into a wet ditch, caused them to be regarded with some suspicion, they acquitted themselves on the whole creditably. In Germany, the Emperor himself personally tested the capabilities of a fast car at the manoeuvres, and was greatly impressed with its performances; while in Switzerland it was found that even on mountain roads they could be used with advantage.

France has undoubtedly taken the lead in the utilisation of automobiles for military purposes, and, as lately chronicled in these columns, in the recent manoeuvres round Chartres automobiles were employed for three purposes: as transport, in the place of horsed wagons, to bring up and facilitate the distribution

FIG. 2.—THE RENAULT VOITURETTE WITH PORTABLE SEARCHLIGHT OUTFIT.

largely used, for the most part with conspicuous success, and on the whole it may be taken that the extensive experiments carried out with them have shown that this new form of conveyance will play a very important part in the warfare of the future. In France, where they were employed for a greater variety of purposes and in larger numbers than in any other country, the reports concerning them are unanimously favourable. In Austria, experiments were made as to their working in a hilly country, and although the bad behaviour of one of them, which

FIG. 3.—REAR VIEW OF RENAULT VOITURETTE WITH SEARCHLIGHT OUTFIT.

of supplies to the troops in the field; as a means of conveyance for staff officers, employed in collecting detailed information as to the distribution and exact position of the fractions of a widely dispersed army, or taking instructions and orders to the commanders of the units; and, finally, to carry powerful searchlights for employment in reconnoitring work.

Of these three purposes perhaps the most important one, or, at all events, the one in which it may be expected that in the immediate future the utilisation of automobiles will be most

largely developed, is the matter of transport. Recent events have shown very clearly the extent to which the movements of an army in the field are dependent upon its transport. It is now well known that the prolonged inactivity of Buller on the Tugela and Methuen on the Modder in the earlier days of the present campaign was mainly, if not altogether, owing to their inability to leave the railways upon which they were dependent for their supplies. The impossibility of conveying these with the transport at their disposal was the reason why they could not seek "the way round," which the American attaché, appalled by the strength of the Boer position, which barred any further direct advance, suggested should be taken. Anything, therefore, which will facilitate the conveyance of the enormous amount of stores of all kinds required to maintain the efficiency of a modern army in the field, must have an important bearing on military operations. And so far as experience gained during peace manoeuvres may be taken as any guide, automobiles can be most profitably employed for this purpose.

In the recent French manoeuvres, a Scotte steam tractor, hauling six wagons, carried in the course of a revictualling experiment fifteen tons of bread and covered eighty-five kilometres (about

our French contemporary, *Le Chauffeur*, give two views of this useful combination. The car itself calls for no special description at this time. At the rear is fixed a small dynamo A, giving 30 ampères at 40 volts. The motor which propels the car is so arranged that it can be connected up to and drive the dynamo when the car is at rest. Fig. 2 shows the portable searchlight plant in operation and Fig. 3 a rear view of the car with the apparatus packed in position ready to travel away to take up another station, A being the dynamo, B the projector, C the tripod stand, and D the cable conveying the electrical current. A small switchboard is fixed in the front of the car.

In view of the practical interest which is being shown in the employment of motor-cars by Continental military authorities, it behoves our War Office to lose no time in inaugurating similar experiments in this country, otherwise we shall find ourselves lamentably behind foreign nations in the matter of military transport.

STRINGENT measures are to be taken by the Huntingdonshire police against motorists going at an excessive speed on the Great North road.

FIG. 4.—A FOOD TRANSPORT TRAIN IN THE FRENCH MANOEUVRES.

Cliché de

[L'Automobile.]

fifty-three miles) in thirteen hours. This shows an average speed of about four miles by the automobile train per hour, including five stoppages for loading and unloading on the road. The experiment lasted till 9 p.m., and it was found that after dusk such a convoy can be easily managed along the road by means of signalling lanterns. Only two men were required for each vehicle, and this alone shows the striking advantage of these trains over horse-drawn convoys; thirty-six horses would have been required for covering a distance of fifty miles with the above-mentioned load, and such a convoy would cover nearly 400 feet of road as against 150 feet, and would have to make the journey in three stages; the extra protection necessitated would also be a serious matter. We are able to publish two interesting illustrations of the Scotte trains used in the recent manoeuvres. Fig. 1 shows one consisting of a tractor hauling a siege gun and its necessary adjuncts; Fig. 4 representing a tractor and five wagons for food transport.

It is not only heavy cars that are finding employment in the French army. We have already in previous issues illustrated a motor ambulance car, travelling telegraph office, postal van, etc., and referred to the large numbers of cars which were employed around Chartres for the transport of officers. Mention was also made a few weeks ago of the portable searchlight plant mounted on a Renault voiturette which was experimented with in the recent manoeuvres. Figs. 2 and 3, for which we are indebted to

NOTIFICATION has been received of the intention of manufacturers to enter, collectively, at least 12 vehicles for the trials of electrical vehicles which are being organised by the Automobile Club for the 5th, 6th, 7th, and 8th of November.

THE British Consul at Chicago, in commenting on the recent automobile exhibition in that city, in the course of a despatch to the Foreign Office, remarks that "there should be a great opening in the United States for automobile or steam trucks, although the country roads and some of the city streets are in a deplorable state. This is a branch that has not yet been exploited, and with a pushing agent and quick delivery a trade could be built up; but if the machines proved successful and took the market, American manufacturers would probably soon start in competition."

THERE is a movement on foot among certain members of the Automobile Club of America, looking toward the obtaining of a decision from the Supreme Court of the State of New York, in regard to the discretionary powers vested in the New York Park Commissioners, under the new charter. The commissioners at first excluded all automobiles from Central Park, but after protest had been made by automobilists, they receded from this position and passed a special rule excluding all motor-vehicles from the park except upon permits issued by them, and restricted up to the present to electric vehicles.

LONDON TO PARIS BY MOTOR-CAR.

BY SIR J. H. A. MACDONALD, K.C.B.

MY friend Dr. Dawson Turner having kindly undertaken to give me a seat on his 10-h.p. Delahaye phaeton from London to Paris and back, we started at 4.30, on a beautiful autumn afternoon, and after painfully threading our way through the busy traffic of South London, had a delightful run to Maidstone—forty miles—which we reached at eight o'clock running slowly in the darkness for the last hour. Next morning, starting at eight, we ran to Folkestone—thirty-five miles—by 9.30, where the car was cleverly hoisted on a wooden frame, and lowered to the deck of the steamer, the seamen being stimulated by an evidently expected, and indeed asked for, tip.

The passage to Boulogne was not of the pleasantest, there being a stiff breeze from the east, but fortunately not making a substantial lunch at Boulogne impossible. On reaching a foreign shore little time passes before one realises that time is not of such consequence to the Continental mind as it is to ours. First, a very leisurely removal of a number of horses from the steamer. By their build we guessed them to be racers, which would account for their being accorded precedence; but as we knew that, although our phaeton was unshipped last, he could easily outstrip and outlast them, for all their breeding, we held them in good-natured contempt. Here there was no frame. Loops of rope were placed over the wheel hubs, and thus was our phaeton hoisted into mid-air. A nervous thirty seconds and the wheels were on *terra firma*. More tips and more contempt of time. For three and a half mortal hours did I sit in the car, consuming my soul and all my light literature, while the doctor and an English agent wrangled with French Custom officers, trying to convince them that a French-made carriage, which was registered in their own books as having passed through France before, should not pay duty as an import from foreign lands. I was not patient, but I looked it, while loungers came around and stared and gesticulated and chattered. At last, at 5.30—we had reached Boulogne at 1.30—the doctor, whose quiet, calm persistence I had admired, mounted to the tiller, “teuf, teuf,” went our horn, and we moved off on the slow speed with the first hat-liftings of Continental politeness, in our case very much on the surface indeed, being much in the mood of Sir Peter Teazle when Joseph Surface tried to ply him with sentiment. Being so late, darkness was on us soon, but we ran twenty-five miles on a most excellent road to Montreuil-sur-Mer, an interesting old fortified town, where we found a good specimen of a French country hotel, the Hôtel de France. Joining the *table d'hôte*, we found ourselves amidst a number of English-speaking people, much to our surprise.

Next morning at eight we were again on the road. Oh, how it did blow that day, making us thankful for two mercies; first, that we were across the Channel, and second, that we were not running by lamp ignition. Judging by past experience, I feel sure that had we been fitted with incandescent tubes, our match-boxes and our patience would both have got very low indeed, and instead of doing 106 miles by 7 p.m., we should have been dribbling along with as many stops as there were finger-posts. And that would have been many indeed, for the excellent manner in which the French roads are indicated by clear notices of places, direction, and distances, puts us in Great Britain to shame. In the middle of the day we stopped at Beauvais and got excellent entertainment at the Hôtel de l'Europe, where we found another car and a motor-tricycle in the yard. The owner of the latter was evidently glad of an opportunity of exhibiting his knowledge of the English tongue, in which he was voluble and intelligible, if not always idiomatically accurate. We learned that he was in the Queen's service, and was on a summer holiday to visit his parents, returning to Balmoral the following week. He had been nine years in England, and said he was more an Englishman than a Frenchman. It was fortunate he told us this, as otherwise we might not have found it out. Here we took in petrol, twice the price it is in England. We rode on and stayed the night at the Grand Cerf, in Pontoise, not the best hotel in

France by any means. Next morning on to Paris, when we drove straight to Messrs. Delahaye's works, that our noble steed, which had carried us right well, might have an overhaul.

The Exposition has had its wonders turned over in every newspaper. I shall confine myself, therefore, to saying only this, that the show of automobiles, both in the Exhibition and in the Annexe at Vincennes, would convince the most rabid anti-automobile partisan that the motor-car is not only coming, but is come, and come strong, so that he must just get reconciled to it, as his father or grandfather got reconciled to “the igoming o' railroads,” assuring him that he, like his progenitor, will find that with reconciliation will come appreciation and enjoyment.

Alas! the show also made it plain how far behind this country is in motor-car manufacture. Not a single carriage built by any British firm is to be seen either at the Exposition or in the Annexe at Vincennes.

After two days in Paris we left it at 10.30 a.m., and slowly moving across the city, got on to the open road about 11.15, and with two stops for breakfast and tea, and a drink of petrol for the phaeton, we ran to Abbeville, 106 miles, by 7.45—a delightful run in charming weather, our only annoyance being that we ascertained finally what we had gradually come to suspect: that there is nothing so effectual for keeping out the sound of “teuf, teuf” as the canvas hood of the ordinary French covered cart. Having two horns on board we were able to make a noise sufficient to prevent the most stentorian-lunged candidate at an election from reaching even the reporters' ear with one single word. Yet often, apparently, no sound penetrated the canvas hood until we were within four or five yards of the cart. Everyone in France is so kind in clearing the road that the failure of “teuf, teuf” when coming up from behind can only be attributed to the non-conducting character of French cart-hoods. Personally I detest “teuf, teuf,” and would be glad of any evidence that would convince the motorist that a melodious double gong was a more effective means of attracting attention than the horrid harsh horn that makes life a trial in Paris. I have made a vow that never will I use a “teuf, teuf” until the double gong is forbidden by law.

This delightful ride was my last. Our steed did nobly, and the pace was often up to the limit that a grey-haired grandfather would care to run at. His life is less valuable than that of child and grandchild, but he values it more than they do theirs. We saw at least twenty-five automobiles during the day, which gave us the exhilarating feeling that things are progressing in the power traction world, and progressing fast; but sometimes too fast. One car did fly by us like the wind. I would not have ridden on that car—to save my life, I was going to say—and will say, for fear of my life. I saw what could be done, but I have no wish to do it. As I said, our steed did nobly—quite fast enough for me. And now came the fly into our sweet ointment—the reminder that care sits behind the traveller, whatever vehicle he may choose to ride on, ready to push his black visage into your face if by the slightest failure you give him his opportunity. The conduct of our gallant Delahaye until we entered the street leading to our hotel was like that of a spirited mount—game to the last. But just as a horse at the sight of the posting inn feels that his work is done, and relaxes, and in spite of all urging will stop at the stable door, so did our power-horse slow down and stop, and make it plain he would go no further. It looked as if he had a will of his own at last, and wished to indicate that he considered 100 miles odd to be enough for the day. By the aid of willing hands he was trundled into the yard. Searching for what was amiss, the steed was justified and the groom condemned. Failure to lubricate sufficiently had caused a pulley bearing to heat, with consequent burning. Before I went to bed all was right again; but, alas! in the morning the doctor put his head in at my window, which looked out on a balcony, and told me not to get up. He and his mechanic had been trying the running with a jacked up wheel, when the jack had overbalanced, and the wheel coming suddenly to the ground, had caused a jam in the differential gear. This meant some hours' delay, and as I was under engagement to be at home by a certain time, I reluctantly had to give up the rest of the run and come home. I heard from the doctor that all was right and that he rode home successfully.

This run will always be a pleasant memory to me, the more so as I came to realise that good, cheerful, sufficient speed can be attained, although a driver is careful, treats the rest of the traffic with friendly consideration, and only goes fast when prudence gives sanction to what eagerness cries out for.

THE ESTCOURT INDUCTION VALVE FOR DAIMLER MOTORS.

MR. E. ESTCOURT, who has introduced several novel arrangements in his Daimler car, has lately devised an improved induction valve for Daimler engines. The valve, as will be seen from the accompanying illustration, is fitted with two springs, one outside and one inside; it is practically a Daimler valve fitted with a special nut on the stem, and a spring in the centre. The centre spring does not come into action at all until the valve has had three millimetres lift, the valve-nut does not then knock against the valve seat, but the spring acts as a buffer, giving a little more lift, and then returns it very much quicker to the seat. The principal advantages of the new valve are: First, the quick return of the valve, giving $\frac{1}{4}$ to $\frac{1}{2}$ h.p.

more on the motor when running fast; second, the inside spring acts as a buffer, and so does away with the knock of the nut on the stem of the valve seat, thus lengthening the life of the valve and valve stem. It is also said to be much quieter in running. Mr. E. Owers, of West Hampstead, has had the new valves fitted to his motor, with the result that he claims to be now able to mount hills on the third speed which formerly he was only able to take on the second speed. The sole right of manufacture of the Estcourt valve has been secured by Messrs. J. W. Brooke and Company, Ltd., Adrian Ironworks, Lowestoft, who inform us that they are now both in a position to supply the same and to convert existing Daimler valves to the Estcourt type.

THE Baroness Campbell V. Laurentz, of Windsor, has a four-seated Locomobile, on which she commenced a long tour on Monday.

PETROLEUM SPIRIT is stored at Cunningham's Motor Works, Clitheroe; and also by Mr. William Rootes, Hawkhurst and Goudhurst, Kent.

THE 1901 pattern of the De Dion voiturette is to be fitted with a 4½-h.p. motor. Under the name "Imperial," the De Dion-Bouton British and Colonial Syndicate, Limited, are introducing a four-seated car of this type. It will be fitted with a reversing gear, and is intended for a speed up to 28 miles per hour.

THE Riker Motor Vehicle Company, of Elizabethport, New Jersey, have lately supplied a curious-looking vehicle to the U.S. postal authorities at Washington. The car is designed especially to meet all the requirements of the service. The distance which may be travelled on one charge is 25 miles and the speed 12 miles an hour. The carrying capacity is 200 pounds in addition to the operator.

MOTOR-CARS ON THE CONTINENT.

(From Our Own Correspondent.)

The Moto Club of Belgium and Driving School.

THE Moto Club of Belgium will hold its general meeting on Sunday next, when several important matters will be under discussion. Not the least interesting of these will be the question of creating a driving school, and if this proposition be ultimately carried into effect the Moto Club will earn the gratitude of automobilists and public alike. Such an institution would be a boon in every town where automobilism is practised, and would undoubtedly minimise the number of accidents which, in nearly every instance, are occasioned by the novice's over-confidence. Of course there is every difference between the quiet seclusion of a school and the bustle of a busy thoroughfare, and I do not for one moment agree that a series of driving lessons under the former conditions would render a man perfectly competent. No, far from it; but I am convinced that a little coaching of that description would take the raw edges off, and give the beginner a little nerve and decision, as well as a good general idea of his car's capabilities. One of the most serious difficulties is to find sufficient space for such an establishment, indeed, in London, for example, one would have to go very far afield to find a suitable spot at anything like reasonable rates. In Brussels, however, this drawback is not so serious, and if the Moto Club carry out their project they should be able to instal the school within a reasonable distance of the centre of the town. And there is no reason why such an institution should confine its efforts merely to the teaching of driving. Technical instruction also might be given, and I am sure that any number of private owners would gladly avail themselves of an opportunity of becoming thoroughly versed in the mechanism of their cars. There is hardly a limit to the possibilities of such a school under good management; so may the Moto Club go in and win.

Demester Again.

ON Thursday, the 18th inst., and Saturday, the 20th inst., Demester, the latest motor-cycle record-breaker, and of whom I made mention in last week's issue of the *Motor-Car Journal*, put in some truly startling performances at the Parc des Princes, during the course of which he annexed five new records. In all he made three trials, on each occasion starting with the intention of setting up a fresh record for the hour, and on each occasion being compelled to stop when but little over the half time had expired. On the Thursday it was rain which pulled him up, and on Saturday tire troubles forced him to retire. When compelled to abandon on the first trial he was going particularly strong, and no one among the spectators would have been surprised to see seventy-two kilometres crowded into the sixty minutes—forty-five miles within the hour! Not bad going, I think you'll agree. On Saturday the strong wind prevented quite so high a rate of speed being attained, but still Demester had succeeded in securing the record for thirty-eight kilometres before one of his tires gave way. During the last attempt a pneumatic burst at the thirty-second kilometre, and the rider escaped an upset by a miracle. But if Demester's dream was not entirely realised he had the satisfaction of beating the previous best as follows:—

	Demester.		Béconnais.
	m. s.		m. s.
30 kilomètres.....	24 59	26 31 $\frac{1}{2}$
32 „	26 39 $\frac{1}{2}$	27 47 $\frac{1}{2}$
34 „	28 29 $\frac{1}{2}$	29 33 $\frac{1}{2}$
36 „	30 24 $\frac{1}{2}$	31 21
38 „	32 15 $\frac{2}{3}$	33 3

Rigal's figures up to and inclusive of twenty-nine kilometres still hold good. Who will be the next candidate for record honours?

The Awards at Vincennes.

I AM now able to communicate the list of awards made by the jury in connection with the two last competitions at Vincennes, awards which have been awaited eagerly by the public and competitors alike. The first of these two contests was known as "Les Poids Légers," and was a competition quite special for the light-delivery class of vehicle. These small fry were required to make a daily journey through the heart of Paris, and during the six days of continuous work 307½ kilomètres, or about 192 miles, were covered. Loads varying in weight from 100 to 300 kilogrammes were carried. The official classification is as follows:—

Gold medals.—No. 3, De Dion-Bouton (petrol); No. 2, Peugeot (petrol).

Silver-gilt medals.—No. 9, Gillet-Forest (petrol); No. 11, Riker (electric).

Bronze medals.—No. 8, Fernandez (petrol); No. 7, Corre (petrol).

The consumption of petrol per kilomètric ton of load was:—No. 3, 0 litre 842; No. 2, 0 litre 9063; No. 9, 0 litre 911; No. 5, 1 litre 235; No. 7, 1 litre 983.

The other competition was "Les Poids Lourds," to which reference was made last week in this column. Here the awards are:—

Omnibuses.—Gold medals { No. 7, De Dion-Bouton (steam).
 { No. 3, Panhard and Levassor (petrol).

Lorries.—Gold medals { No. 8, De Dion-Bouton (steam).
 { No. 9, Peugeot (petrol).

" Silver-gilt medal, No. 4, Panhard and Levassor (petrol).

" Silver medal, No. 10, De Dietrich (petrol).

Delivery Vans.—Silver-gilt medal, No. 3, Riker (electric).

From these lists it is evident that the older established firms continue to have matters much their own way, and that none of the new productions can seriously compete with them. The jury, consisting of MM. Forestier, Quesnay, and Louis Mill, Baron Zuylen, Sir David Salomons, Count Talleyrand-Périgord, and Count Chasseloup-Laubat, will doubtless publish full details of these two competitions in due course, and they will certainly be awaited with considerable interest.

Last Sunday's Motor Race.

LAST Sunday's motor-cycle race at the Parc des Princes was entirely spoilt by the rain, indeed, the wisdom of deciding the race at all on such a slippery track may well be doubted. The distance was twenty kilomètres, and the six competitors were Béconnais, Bertin, Fossier, Rigal, Reith, and Léopard. Rigal, mounted on his 12-h.p. Buchet, started off at such a furious pace that in the first lap he secured a hundred metre lead upon the field, and actually accomplished the 666 mètres in forty-one seconds. But his triumph was but of short duration, for during the second lap a terrific sideslip caused one of his tires to burst, and *voilà!* Béconnais also could do no good, and the rain brought about his eventual retirement, while it caused numerous *pannes* to all the other racers except Bertin. This latter cyclist had no mishaps from end to end, and in accomplishing the distance in 18 minutes 24 seconds he quite out-reached his rivals. Fossier secured second place, and Reith third, with Léopard acting as whipper-in. Motor racing is dangerous enough in all conscience on a dry track, but with a wet surface it is absolute madness, and the organisers of sports meetings should not call upon the men to turn out under such conditions. Of course, they plead that the public must not be disappointed, and when they have to control such a disgraceful crowd as the one which was at the Parc des Princes on Sunday last, one is not surprised at their disinclination to change the programme. But even to please the crowd the competitors should not be forced to take the track under conditions so terribly dangerous, and the sooner that the public realise that motor races will only be decided on dry tracks the better it will be all round.

An Accident in Paris.

WHAT might have been very serious accident took place some days ago to one of the automobiles owned by Baron Henri de Rothschild, and it came about in this way. At about two o'clock in the afternoon an electric tramcar was slowing up at the station in the Place Percire, when the Baron's carriage, driven by an engineer named Martin, attempted to cross the rails, the driver apparently thinking that the tramcar had stopped. A violent collision ensued, and the fore part of the automobile suffered severely. The *chauffeur* jumped from the car and escaped scathless. The damaged carriage is a coupé, but the car driven by Baron Rothschild himself is a 26-h.p. Daimler, and this would appear to be his favourite steed. No automobilist is better known to Parisians than the Baron, for mounted on his big red car he is to be seen daily speeding through the streets of the capital, and the huge Daimler itself commands attention. Even the *cocher* makes way for the German giant.

The French Prime Minister Joins the Ranks.

AMONG the latest converts to automobilism is the Prime Minister of France, M. Waldeck-Rousseau. He has yielded to the fascination of the steam motor-car, and may be expected shortly to purchase one of the vehicles for his own delectation. M. Waldeck-Rousseau has, indeed, been observed undergoing initiation into the mysteries of the new locomotion and experimenting in motor-driving even in the solemn precincts of the courtyard of the French Home Office. He made trials in sharp turnings, in sudden stoppages, and backing, under the direction of M. Serpollet, on one of the latter's 8 h.p. cars. It is now M. Loubet's turn to fall a victim. The President of the Republic has expressed a wish to go for a ride in an automobile, and the trip will take place at an early date in the Bois de Vincennes.

Another Royal Automobilist.

JUST as M. Waldeck-Rousseau was descending from the car, the King of Belgium drove into the courtyard for the purpose of leaving his card. King Leopold was but in a horse-drawn carriage, and the sight of the Minister *en automobile* may have had something to do with his subsequent visit to Charron's *garage*, where, it is reported, a splendid 12-h.p. Panhard car was purchased. The King of Greece, who is also at this moment in the home of automobilism, might well follow this example and so add yet another to the list of sovereigns and royal personages who appreciate the delights of the new mode of locomotion.

Closing Fêtes at Vincennes.

To mark the closing days of the Paris Exhibition a couple of fêtes are in course of organisation to take place at the end of the present month. One of these will be known as the "Fête des Transports," and will be held on Wednesday, the 31st inst. The date of the other fête has not yet been decided upon, but its programme has already been prepared, and presents some truly attractive features. There will be a series of races round the Lac Daumesnil for motor-cycles, voiturettes, and cars, and in addition the usual gymkhana sports. The motor-boats, too, have not been overlooked, and a couple of races will be contested on the lake. It promises to be a very interesting automobile gathering, but all depends upon the weather.

The French Automobile Club.

AT the meeting of the committee of the A.C.F. last week, Count De Dion's proposals to organise an automobile tour of France, on the lines of the English 1,000-mile Trial, was adopted in principle. In May next there will be held an accumulator competition; in June a motor-cab and light delivery van competition; and in October, 1901, the *Poids-Lourds* competition is to be repeated. It has also been decided to organise in December next a cycle and motor-car exhibition, in conjunction with the Chambre Syndicale de l'Automobile and La Chambre Syndicale des Fabricants de Cycles.

THE MALLIARY VOITURETTE.

M. GABRIEL MALLIARY, of Rue Collin, Puteaux, near Paris, has sent us particulars of a new motor-voiturette he has lately put on the market, and of which an illustration is given herewith. M. Malliary fits the motor and the whole of the transmission on an independent frame of tubular construction, to which any type of carriage body can be fitted. The illustration shows a three-seated spider, but a four-seated *tonneau* can be substituted therefor, the builder making a

FIG. 1.—THE MALLIARY VOITURETTE.

speciality of a body which can form a small delivery van with seats for two persons or be quickly converted to a *tonneau* for four persons.

Coming now to the mechanical part of the car, it will be seen that the engine is located under a bonnet in the fore part of the frame. M. Malliary fits a motor of his own design; it is of the single vertical cylinder type of 5½ h.p. (Fig. 2). It will be noticed that the engine is air-cooled, the fins being large and continued around the explosion chamber and exhaust valve, the builder claiming that by his system of construction he gets almost as good results as with a water-cooled engine. However, recognising that many motorists prefer the latter, notwithstanding the increased weight, etc., he has arranged to fit a 6 h.p. water-cooled single-cylinder engine, together with pump and radiator when desired. The motor is provided with a regulator, by

FIGS. 2 AND 3.—ELEVATIONS OF MALLIARY AIR-COOLED MOTOR.

means of which the speed can be varied between 500 and 1,600 revolutions per minute.

Three speeds forward—7½, 16, and 23 miles per hour—and a reverse motion are usually provided, but if necessary the backward motion can be omitted and a fourth higher forward speed substituted. The power of the motor is transmitted through a friction clutch to a short variable-gear shaft gearing with a longitudinal shaft below. The latter is provided with universal

joints and terminates in a bevel pinion meshing with the corresponding bevel wheel surrounding the differential gear on the rear live axle. Steering is controlled by an inclined hand wheel on the standard of which is mounted the change speed lever and the handles controlling the carburation, ignition, etc. The steering pillar, too, is pivoted at the bottom, so that it may be pushed out of the way to allow free ingress to the car.

Ample brake power is provided, there being a pedal-operated band brake around the differential gear on the rear axle; this brake works in conjunction with the friction clutch, that is to say, the latter is withdrawn and the motor thus put out of gear on the application of the brake. A second pedal controls band brakes on the hubs of each of the rear wheels. The car complete weighs about 5 cwt.

THE DAIMLER MOTOR AND TRANSMISSION GEAR.

IN connection with the discussion on the above subject in the *Automobile Club Notes*, Mr. J. Ernest Hutton, of Northallerton, sends the following letter:—"It is a matter of great interest to read Mr. Worby Beaumont's letter on this subject. It would be impertinence to attempt to criticise an engineer of such ability and prominence as Mr. W. Beaumont; but there are certainly some points in his statement which are contrary to the experience I had of the car in question (sometimes irreverently called the 'camel'). I never observed any greater difficulty in changing the speeds, which I was able to effect absolutely without noise.

"With regard to the inertia of the fly-wheel, surely the fly-wheel itself is so small as compared to the total mass of the car, that when the engine is in gear (and supposing the friction clutch be not slipping at all), the whole car becomes an 'accumulator,' when in motion. With regard to the gear which I recently had occasion to take out of the Panhard in question, this appeared to be in wonderful order, and I could not see any more wear, resulting from the twin engines, than was formerly caused by the 6 h.p. ditto, in the earlier days of my novitiate. The practical result may be of interest; when a 6 h.p. car, I did well to average sixteen to twenty miles per hour, and my last good run on the twin was from Northallerton to Peterborough (160 miles) in 5½ hours. No stop, except for lunch."

MR. GEORGE SMITH, 55, Fisherton Street, Salisbury, is the winner of the motor-quadracycle offered as a prize in a recent competition in *Answers*.

A FIRM at Dorchester, Mass., U.S.A., is building a steam delivery wagon for the publishers of the *Pittsburg Press*, Pittsburg, Pa. It weighs 1,500 pounds, has an 8 h.p. engine, and is fitted with wire wheels and double tube pneumatic tires.

A NEW apartment house in course of erection on West End Avenue and Seventy-ninth Street, New York, will have attached to it a *garage* for housing the motor-cars of tenants. Facilities for charging the electric vehicles are provided on the first floor, and the second floor is intended for living apartments for the vehicle attendants.

WE learn that the Thomson Motor-Car, Limited, of Melbourne, Victoria, are now building two four-seated steam cars of a standard type, which they hope to list at under £200, and which will be capable of running fifty miles without recharging. The company is considering the question of establishing large works near Melbourne.

MOTOR-CYCLES figured in but two events at the race meet run in connection with the opening of the Tri-State Fair at Guttenberg, N. J., recently, the machines being divided into classes. The five-mile race for four-wheeled petrol vehicles, carrying two passengers and weighing less than 1,000 pounds, was won by Mr. C. J. Field, of Brooklyn, on a quadracycle, with Mr. F. D. Craven, New York, second, and Mr. J. Louveguéz, Brooklyn, third; time, 11 min. 13.3 sec. In the five-mile race for tricycles Mr. C. S. Henshaw won in 8 min. 24.3 sec., beating Mr. Louveguéz and Mr. S. R. Atkinson.

HERE AND THERE.

THE committee of the Automobile Club are inviting manufacturers and agents to send authorised representatives to a meeting which is to be held at the Club, 4, Whitehall Court, London, S.W., on Friday, November 2nd, at 5 p.m., to discuss what should be the nature of the event, if any, in 1901, which would correspond with the "1,000-Miles Trial" of 1900.

AMONG the new candidates for membership of the Automobile Club are Col. Stratton Bates, Major Helbert, and Mr. Harry Tangye, of Birmingham. Major Helbert is proposed by Sir David Salomons, who has recently presented eight interesting engravings, illustrative of road travel, to the Club.

WHEN riding in London always obey the policeman. Two well-known motorists were journeying along Oxford Street the other day, and at the Southampton Row corner were stopped by Robert Constable, who was regulating the traffic. They went about three feet beyond his majestic person, and it was interesting to see the gentleman at the wheel get down and push his car to a level with a bus that had halted. He did it with a grace and courtesy that quickly re-established him in the esteem of the policeman. Such actions are better than fuming, and help to sustain the lenient bearing of the average policeman in the London area towards automobilists.

HERE is an imaginary police report on a motor-car which passed through a country town the other day:—

"A motor-car has just flown through the town. I received telephonic intimation of its coming from a station twenty miles away. Hardly had I put up the receiver when a loud noise not unlike a screeching owl and small foghorn was heard, and as I got to the door I saw a whirling cloud of dust and heard "teuf-teuf." From that ominous sound I concluded it was the motor-car of which I had warning. No regard was paid to the bye-laws of the county. I learned afterwards that for a distance of five miles horses and pedestrians dodged in every direction, but before they had time to get out of the way the machine had curved past them and was fast fading in the distance. At the corner of the market-place a woman was about to cross. She was half-way across, when the machine loomed up and was so close to her that she had not time to get out of its way. This did not bother the driver, as he whirled the machine around her in a sort of semi-circle, without slackening speed, and passed on without even looking around. The woman was so frightened that she collapsed in the street and came near fainting. She was helped to her feet by passers-by who had seen the occurrence. All the way up the town, horses and pedestrians were frightened until they could scarcely breathe at the narrow escapes. Had it been possible to get hands on the careless driver he would have been arrested, but he was far out in the country before any one could collect their wits.

"P.S. (added two days later).—I have since ascertained that the motor-car of which I had telephonic communication broke down before it got out of the town from which my information came. The inspector instructs me to say that the car which I referred to as going at a lightning speed was the new motor-dust cart acquired by the town, and that its speed was probably four miles an hour. Are we to prosecute on the information contained in my first report?"

MR. C. JARROTT has not given up the attempt to do forty miles inside the hour on his motor-tricycle. He intended to go down to the track at Canning Town for the purpose on Friday, 26th, but, unfortunately, owing to the *Journal* going to press on Thursday evening, I am unable to give the result this week.

I LEARN that Mr. J. R. Egerton has been at Normanhurst, Battle, teaching a man to drive and understand the ways of the voiturette which Lord Brassey recently purchased. Since Lord Brassey has had the car it has been out nearly every day with

Lord and Lady Brassey aboard or else some friends staying at Normanhurst, Mr. Egerton driving.

As recently announced in these columns, Messrs. Dennis Bros., of Guildford, have got into their new works and show rooms "The Barracks." I am able to give a general view of the show rooms on the ground floor, where the offices are also situated. The upper part of the building is devoted to factory operations, the first floor being for the machine shop and plating

departments. Land adjoining the works has been secured for further extensions. The new works have enabled Messrs. Dennis Bros. to double their output of the Speed King motors. Just at present they are experimenting on two new types of motors, about which more anon.

WHILE in Caithness assisting the candidature of Mr. L. Harmsworth, Mr. Stanton made himself thoroughly acquainted with the roads and traffic of the district with the view of promoting a system of motor-car service. He is strongly of opinion that both for goods and passengers such a system would be of immense benefit to the public and would prove a financial success. Mr. and Mrs. Stanton left for the south by ordinary train. It was his intention to have taken the road across the Ord, but the weather proved unfavourable, and the motor-car, to which some local people go the length of attributing the success of Mr. Harmsworth's candidature, was conveyed south—also by rail.

MOTORING seems to have got a great impetus in Scotland through the elections, but, so far, I have heard of only one lady motorist resident north of the Tweed. She is Miss Speedie, of Dollar, and has driven more than 900 miles on her De Dion voiturette.

DURING the recent election the Anglian Engineering Company, Ltd., of Stowmarket, drove Mr. Ian Malcolm, M.P., on an International Benz car more than 1,000 miles in thirteen days. There was no hitch during the whole of the time—a performance which, considering the roads in north-west Suffolk, must be regarded as capital. The company is able to undertake repairs, and also to charge the accumulators of any electric cars going their way.

NEXT Thursday the first election of councillors for the new London boroughs will take place. These councils will be the highway authorities within their respective areas; hence the interest that automobilists should feel in the election, and in the success of gentlemen who will give the care of the roads their serious consideration.

MR. F. GUY LEWIN has opened a dépôt in High Street, Kingston-on-Thames, where, as the Kingston Motor Company, he will store petrol and execute repairs to motor-vehicles. Seeing the numbers of automobilists passing through Kingston, he should be kept busy in connection with his petroleum-spirit department.

LOLLIUS.

CORRESPONDENCE.

AN INGENIOUS LOG.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I enclose one of the road logs as made by a very useful, interesting, apparatus supplied and fixed to my car by Mr. Harrington Moore. The principle of the apparatus is a clock that is set to the correct time. This clock rotates the paper dial; at the same time a flexible shaft, operated by the driving or road wheel, marks a line across the space ruled off into quarter-miles on the edge. Each mile is shown by the line from the outside edge to the inside edge of this space; the pencil then flies back and commences the next mile. As the log shows, the apparatus was set going at 2.50 p.m. The car was stationary until 3.5; it was then run three-quarters of a mile in about four minutes, then stopped for five minutes. A mile was then run in about four minutes, this being followed by a stop of half-an-hour; then another mile in five minutes and a stop of five minutes, followed by just enough movement to complete the mile. Continuing the record shows a stop of fifteen minutes, quarter of a mile run; stop of five minutes, quarter of a mile run; stop of five minutes, then nearly half a mile run; five minutes stop, a run of seven miles in about twenty-five minutes; a stop of fifteen minutes, and then a slow run of seven miles at about four miles per hour (the latter was a torchlight procession round Lowestoft), and three

stops of about five minutes each. I have given the reading fully, so that your readers may quite understand its working. The whole distance run was nineteen miles, this being also shown on another dial.

Lowestoft, Oct. 20th, 1900.

Yours truly,

E. ESTCOURT.

LEEDS TO BRIDLINGTON.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Having seen accounts of runs by several of your readers, I send for your perusal a trip on a petrol-driven car made by Messrs. A. Dougill and Company, Ltd., of Longclose Iron Works, Newtown, Leeds. On August 4th (Bank Holiday Saturday) we started at 4 o'clock from the works and travelled along the York and Tadcaster road until we reached the Selby road, then through Garforth Bridge, and reached Selby at 5.30. There were on the car Mr. Alf. Dougill and his two sons, Mr. A. W. Dougill driving. We had about 3 cwt. of luggage. We passed through Selby and Spalding-on-the-Moor, to Market Weighton, with only two stops for a few minutes each time to look round the machinery and refresh the inner man. When we got past Market Weighton we had some very steep hills to

ascend, which had to be taken at about four miles per hour on the slow speed until we got to the top of the hills overlooking Middleton-on-the-Wolds, where we arrived just as it became dark. Had it not been for a train just going past a level-crossing we should have run into a steel wire rope which is stretched across instead of a gate, and pulled up or let down as occasion may require from a house close by, which I think is a very dangerous practice. We then went on until we reached Driffield at about 9.15, where we put up for the night at the Old Bell Hotel, and a very pleasant evening we had. The weather was exceedingly cold, and we had a very strong east wind against us all the way.

On the next morning we had a pleasant run from Driffield to Bridlington in three-quarters of an hour, and put up at the Waverley Hotel, Prince Street. The car, which seats four persons, is run by one of Dougill's horizontal, carburetted air motors of 7 b.h.p., and ran very smoothly indeed; and I shall recommend every medical man to invest in a motor-car.

Yours truly,

E. H. BRAITHWAITE, M.B.

Station Hospital, Leeds, October 19th, 1900.

THE ALTRINCHAM CASE.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Kindly excuse my reverting to the Altrincham case which you spoke of last week. There were two charges of excessive speed dealt with by the Altrincham magistrates who attended court the other day. A comparison of the two cases forms an interesting study. Ours was for driving a motor-cycle at an excessive speed on the highway, and the other was against a carter for driving a horse at an excessive speed in the streets, both to the danger of the public. There is obviously a great deal of difference in these two cases, and I leave impartial people to judge which of the two is the most dangerous to the public.

We drove our motor on a lonely country road in broad daylight, with hardly a soul to be seen; the carter drove his horse and cart down the main street of the town when it was pitch dark, and when it was crammed with people, so that you could hardly move. The street is only twenty feet wide, and very dimly lit. We were sober, and slackened to a crawl whenever as much as a vehicle hove in sight in the distance; the carter was hopelessly drunk, and charged down this narrow street at the speed of fourteen miles an hour, scattering the terrified people in all directions. He was even forced to admit that he had driven on the pavement at times. I suppose it gave a greater zest to his pleasant performance, and added an additional excitement, in pursuing the panic-stricken people on what they fondly hoped was a refuge. There had been an agricultural show that day and this street was packed with people. How it was he did not kill and injure at least a score of them remains a miracle! Talk about a motorist endangering the public!—what do you call this?

As for ourselves, in our afternoon's motoring we saw precious few of the public to endanger; and although it was proved we had not endangered anyone, we were nevertheless fined £3 2s. 6d. in all. The carter was fined 10s.—Yours truly,

London, W., Oct. 20th, 1900.

LEOPOLD CANNING.

[We commented on this case on page 549 of last week's issue.—ED. M.-C.J.]

THE police in Merionethshire have been instructed to take proceedings against motorists going at furious rates down dangerous places in the district.

IN addition to the facilities mentioned last week for obtaining seats on vehicles journeying to Southsea, on the occasion of the Automobile Club's forthcoming run, the Motor Manufacturing Company, Limited, of 47, Holborn Viaduct, E.C., will run a vehicle the charges for seats on which are as follows:—Down journey 12s. 6d., up journey 10s. 6d., both ways one guinea, to return Sunday or Monday at the convenience of passengers. Similar opportunities are also being provided by the London Motor Company, Limited, of Tottenham Street, W.

THE AUTOMOBILE FETE IN PARIS.

(FROM OUR OWN CORRESPONDENT.)

THE *Sport Universel Illustré*, that well-known Parisian paper to whose efforts so many automobile gatherings have been due, can be heartily sympathised with in the bad luck which accorded them such a miserably cold, bleak day as was Saturday last for the holding of the annual voiturette fête at Longchamps. These festivities are all very well, but their success depends principally upon the weather, and that in evidence on the 20th inst. was distinctly unsuited to floral fêtes. Given fine weather no more agreeable promenade *en automobile* can be made at this time of the year than a run through the Bois de Boulogne, and had the sun favoured Saturday's proceedings with his presence a goodly gathering would undoubtedly have assembled at the Rond-pont de Longchamp. But to this essentially ladies fête but few ladies came, for the majority found their fire-sides much more to their liking. It was certainly an incongruous sight to see the flower-bedecked cars, mounted by fur-clad, blue-nosed *chauffeurs*, scurrying through the Bois under a sky as dark and threatening as witnessed in the depth of winter. But all this was not the fault of the promoters, for, in common with the rest of mortals, as weather makers they are not in their element. Only some of us would be glad not to have to attend autumnal fêtes, so next year arrange it for September at latest, if you please, Mr. Bréviaire. Maintaining the unpunctuality so striking at last year's gymkhana, a late start was made with the programme, and we were first regaled with a steering competition in which the great majority of voiturettes were driven by ladies or children. The usual proportion of dummy figures were knocked down, run over, and replaced upon their legs, silent and uncomplaining as ever. After extraordinary feats had been accomplished, both in avoiding and hitting the members of this tin populace, a halt was called, and the judges made their selection for the awards, published at the *déjeuner* later on in the day. These prize-winners were:—M. Rudeaux (Darracq); M. Raoul d'Arnaud (Sirène); Mme. Braun (Peugeot); Mme. Richard (Richard); Mlle de Vèriane (Riancey). Then came the *défilé*, which brought out a goodly number of cars, and then the usual gymkhana events, interesting enough for the participants but wearisome in the extreme for the spectators. A distribution of banners, followed by the usual march past the empty stands, and then a rush to the Châtelets du Cycle, where *déjeuner* awaited the competitors and organisers, as well as those of the spectators who had been sufficiently courageous to stay to the end. Then, under the presidency of Monsieur Jean Romain, director of the *Sport Universel Illustré*, and warmed by the genial influence of a capital lunch, the *convivres* speedily forgot their grievances against the weather, and when at last a move was made for Paris one and all were again happy and contented. During the repast the various awards were made known, but the list being somewhat lengthy I only propose to mention the names of a few prize winners known to English automobilists. These were: Mmes. Richard, Briene, Turgan, Popp, and Suberbie among the ladies, and MM. Hautier, Vinet, and Bonnard among the men.

THE ROSSEL STEAM TRACTOR.

M. E. ROSSEL, of Lille, France, one of the early workers in the field of the petroleum spirit motor-car, has recently been devoting attention to steam vehicles and at the Paris Exhibition he shows a curious-looking machine intended for the haulage of canal boats. The tractor, of which an illustration is given herewith, has a vertical, coke-fired, water-tube boiler of the quick steam raising type, and a double cylinder horizontal reversing engine of 12 h.p. The two cranks of the engine make an angle of 90deg. with each other. The admission is variable, from 0 to 80 per cent. of the stroke, and the engine speed can run up to 350 revolutions per minute. The rear wheels are the drivers. They are cast with an internal gear on one side, with which engage the pinions of a differential shaft. The differential shaft is connected to the crank shaft by several sets of spur gears, which are engaged by means of positive clutches. Two speeds ahead and one reverse are provided. The higher speed is used for towing empty boats and the lower for loaded boats, up canals. The front axle, which is provided with steering spindles for pivot steering, swivels around a pin fastened to the frame, centrally between the two wheels. The frame has, therefore, only three points of support, and will accommodate itself to all conditions of road surface. Two men are required to operate one of these tractors, one for tending the boiler and the other one for steering and controlling the vehicle. It is claimed that the machine illustrated will haul a train of six canal boats, each weighing 200 tons, at a speed of 5 km., or slightly more than three miles an hour, against the stream.

THE ROSSEL STEAM TRACTOR FOR CANAL BOAT HAULAGE.

THE Crest sparking plug, illustrated in our last issue, is

being made with a metric screw thread and adapted to fit motors of French manufacture.

Up to date thirty-eight entries have been received for the alcohol motor competition which is fixed for the 28th inst. The course is from Paris to Rouen.

MAPS and guide books simply afford the motorist a basis for what sailors are wont to term "dead reckoning." After consulting the maps and the books the user of a motor vehicle may, with more or less accuracy, declare he has travelled "about" so many miles. Whether he has actually done so is, and always must be, a question in which doubt is greater than certainty. The difficulty is, however, removed by the compact little odometer made by the Veeder Manufacturing Company, of Hartford, Conn., and which is being introduced into this country by Messrs. Markt and Company, 25 and 26, Shoe Lane, London, E.C. The odometer is made with a flange base through which two holes are drilled to make it readily attachable to any special clip which may be required. The device registers up to 10,000 miles, the first row of figures representing fractions of a mile, the second row miles, the third tenths of miles, etc. The odometer is made for fifteen different sizes of wheels, from 24in. up to 50in. Practically every motor-car requires a different fitment in the way of clips, and Messrs. Markt are prepared, if furnished with drawings, to make these at a reasonable charge.

THE PROGRESS OF THE AUTOMOBILE.

By PROFESSOR R. H. THURSTON.

(Concluded from page 385.)

PROBABLY no one familiar with the situation and with the construction and the use of the automobile as now supplied the market, and as used by the automobilists of the closing year of the nineteenth century, will hesitate to assert the full demonstration of the following points: (1) Automobile operation may be safely effected and no greater dangers attend it than are accompaniments of horse drawn vehicles. (2) Speeds may be attained, and maintained, higher than can be either attained or maintained by horse-power:—doubled speeds for short distances and trebled for long distances. Length of route may be unlimited. (3) Heavy gradients may be surmounted and any road fit for horse-drawn vehicles may be traversed by the automobile. (4) A good construction of automobile machinery in proper hands—not necessarily those of a skilled mechanic—is, on the whole, much less liable to serious disability than is the horse. The better and more expensive the automobile the less

to be performed, the advantages of the automobile over the horse-drawn vehicle are unquestionable. These advantages are, in general:—(1) Reduced cost of transportation. (2) Greater speed and better control of speed. (3) Absolute docility. (4) More perfect "handiness," as a naval man would say. (5) Sanitary gains of very great importance. (6) Less cost of maintenance of pavement and roads. (7) Less trouble in crowded city streets from interruption of traffic, as a consequence of the less space occupied and better action of the automobile. (8) Much greater quiet, especially in traversing paved streets. (9) Reduced space and cost in storage. (10) Extinction of the nuisance and costs of the stable. (11) Abolition of danger from "run-aways." (12) Continuous decrease of costs, as against steady increase with horses. (13) Resultant upon the introduction of the automobile, to the exclusion, largely, of the horse, will come such improvement of our city streets and country roads as has only been just begun by the bicycle and its friends, improvements particularly adapting them to the new vehicle.

The automobile is the coming feature of our modern life. The bicycle has had its period of rapid development and of popularisation, and the automobile is its natural successor. The

THE PEUGEOT MOTOR-BROUGHAM. (See opposite page.)

this liability to invalidism; the more valuable the horse, the more is he liable to injury and illness. (5) Costs of maintenance and operation are less with automobiles than with equine outfits. With heavy work the difference is immensely in favour of the automobile. (6) Commercially, the well-built horseless vehicle, of whatever class and in whatever line of work, is greatly to be preferred to the horse and vehicle and its accompaniments of stable, attendance, untidiness, unsanitary conditions, and obtrusiveness. (7) There are no serious objections to the general use of the automobile for either heavy or light, slow or speedy, traffic. There are fewer and less serious objections than were raised to the introduction of the street tramway; while there is open to them an enormously more extensive field. (8) The tires of the automobile, if not pneumatic or of rubber, may be made of any desired width, and, of whatever breadth, will aid in the improvement and permanent maintenance of the roads, while the hoofs of horses injure them. (9) Weights of automobiles, for similar powers and loads, may be made less than the weights of horses with their vehicles.

Whichever of the now more or less successful among the existing systems of automobile be adopted for the specific work

bicycle is coming to be the every day instrument of business and pleasure. The day of excitement and of hysteries has passed with it, and we are settling down to its sensible but limited use. The automobile is a vastly more important development, and it has an immensely larger and more serious and extensive field before it. The "wheel" has taken its place among the common necessities of every-day life and largely passed out of the field of the "fad," pure and simple. The automobile is coming in to take up a great work, and one of much larger range and higher importance. It is bringing to the aid of transportation of all kinds, light and heavy, passenger and freight, work and pleasure, the aid of the inventor and of the motor-machine. It is adapting itself alike to the demands of the rider in the park and of the tradesman sending home the family dinner, to the needs of the delivery wagoner and of the postman, to the transportation of tons of ironwork and of ounces of *lingerie*, to the slow traverse of the ploughed field or the deliberate movement of the "auto-van" and as perfectly to the express speed of the racing vehicle over the one-mile track or over the hundred or the thousand mile course. Pleasure, convenience, business and public advantage, and all industrial economies are about to be promoted by

its evolution, as power, speed and safety and handiness are gained, and costs are reduced in construction and in operation.

The horse will be relegated to a narrower field of work, and our streets will, in time, become as perfect sanitarially as they are becoming, in well-managed cities, in their construction. The runaway horse, the constant source of anxiety and frequently of actual danger in the city streets and in the parks, will disappear, and the lives of mothers and grandmothers will be rendered thus more serene. Ericsson's automobile fire-engine of 1860 will have many useful successors. Cross-country routes will gain in attractiveness while losing the risks of ordinary coaching, and the hamlets and farms off the line of the railways will become accessible and comfortable as homes and pleasure resorts for all seeking the quiet of nature and the pleasures of country life, as well as for their native workers and the small farmer or the retiring millionaire. Hauling timber, transporting ore, carrying merchandise over the common highway, delivering the morning purchases in the city, driving in the country or through the park, and going to the opera in the evening—each use will find its best and most satisfactory form and type and special construction, and the civilised world will be transformed through another and hardly less wonderful evolution than that which, in the field of railway and steamboat transportation, has characterised the century just expired.

Inventors and inventions of the older sort, amateurs in science and art, and a spontaneous inspiration, are now nearly gone by. The invention of to-day is simply a design adapted to a precisely defined purpose by a trained designer, familiar with the principles and practice of his art, who proceeds, by direct and safe and certain routes, to his end, adapting a mechanism of as exactly defined plan and method of operation to the work. The educated and professionally-trained designer has succeeded the ignorant, but often marvellously skilful and ingenious, inventor, whose crude devices required months and years, often, of experiment, trial and error, to work into practically useful shape and profitable form. To-day one trusts no inventor, if he lacks that scientific knowledge which is essential to success as a designer. It is the expert in the field in view who, to-day, determines just what to do and in what manner to reach the desired end. Every successful professional is a specialist, and each is compelled often to say—as did a distinguished surgeon when I once asked him a question requiring special knowledge for its answer—"I cannot tell you that—but there is another man who can!"

But the man who can say just what is to be the future of the automobile, what form of motor, if any, is to be the one exclusive motor, or what will be the ultimate distribution of work among the perhaps various permanent types of horseless vehicles has not yet appeared. Only this can be said with probable truth: The steam-engine is not likely to see any very great advance in the immediate future and is too near its practicable limit of perfection, probably, to have much chance of success if that success depends upon extensive improvement in construction and type or in thermodynamic perfection. The internal combustion engine has a wider range of possible improvement, and to this extent has larger promise, but with no certainty that its defects will be removed at any early date. The storage battery and electric propulsion have a similar relation to the steam-motor, and, like the gas-engine, await the genius who can reduce still serious infirmities, and give a very reasonable degree of approximation to the ideal prototypes.

The trend of progress of the automobile, in all directions, is toward perfectly well understood and fully recognised ideals and limiting perfection and the educated, professionally well informed and experienced engineer will undoubtedly find many ways of pruning away defects and of importing improvements until that limit of practicable and economic advance is reached for each of these interesting types of self-propelling vehicles. This is not the work of the amateur in any line, and the day of the self-appointed promoter of great advances in the industrial arts has gone by, never to return.—*The Automobile Magazine.*

THE road between Farnham and Petersfield is reported to be in a very bad condition.

THE PEUGEOT MOTOR-BROUGHAM.

THE illustration on the opposite page shows the brougham made by the Peugeot Company, of Audincourt, Doubs, France. It has accommodation for two inside passengers, with a movable seat for an additional one if required. It is propelled by a two-cylinder horizontal motor of 6 h.p., acting independently, so that one cylinder only may be used when running on easy roads. Four speeds are provided, and as the running of the motor itself is regulated by the admission of the gas mixture, the rate of progression may be varied as required. The wheels are

FIG. 2.—PLAN OF FRAME OF PEUGEOT BROUGHAM.

of the cycle type, shod with pneumatic tires, the vehicle altogether presenting a very elegant appearance.

A LATE addition to the light steam vehicle class is that of the Hoffman Bicycle Company, Cleveland, O. The boiler is wound with piano wire and is said to be tested to 600 pounds' cold water pressure.

MR. A. J. DRAKE, works manager to the Daimler Motor Manufacturing Company, has been appointed general manager of the Kingsbury Motor Construction Company, Ltd., Edinburgh, who have purchased the works of the late Madelvic Motor Company.

MR. C. G. WRIDGWAY, who is now with the De Dion-Bouton Motoret Company, Brooklyn, N.Y., has been awarded by the Chicago Inter-Ocean Automobile Show Committee a special championship gold medal for his run of 600 miles on a De Dion voiturette in record time while en route from New York to Chicago.

THE "Albion" is the name of a two-seated petroleum-spirit motor-car which is being put on the market by the Albion Motor-Car Company. The motor is of the two-cylinder horizontal balanced type. It is water jacketed, and runs at a comparatively low speed. It develops about 5½ h.p. on the brake, and is able to propel the car when fully loaded up any moderate incline at a speed of twelve miles per hour, any steeper incline being negotiable at five miles per hour. There is also a reverse speed of about three miles per hour. The ignition is electric, the current being generated by the motor itself. The wheels are of the artillery pattern, with wooden spokes, and are fitted with solid rubber tires. The car is provided with two powerful independent brakes. The oil tank holds four gallons of oil, sufficient to run the car one hundred miles when fully loaded.

A PNEUMATIC TIRE PUNCTURE HEALER.

SO frequent have been the troubles with pneumatic tires fitted to motor-cars, that any device which will tend to remove the difficulty is sure to receive attention at the hands of motorists. This object is claimed to be achieved by a new puncture stop named "Millennium," which is being put on the market by the British Steam Traction Syndicate, Ltd., of 37, Walbrook, London, E.C. Puncture-healing liquids are by no means new, the chief drawback to those hitherto used being found in their deleterious effect on the rubber of the tire. So far as the new healer is concerned, it is claimed that not only does it not adversely affect the rubber in any way, but that it is, in fact, a preservative of the same. "Millennium" is compounded of certain chemicals, which, after having been subjected to a special treatment, form a homogeneous mass possessing certain peculiar properties, which are said to constitute it an ideal substance for automatically and instantaneously closing and hermetically sealing punctures and perforations in pneumatic tires, both for cycles and motor-cars. It takes the form of a liquid of the consistency of cream; it is, however, not sticky, nor is it inflammable. All that is necessary is the injection of a small quantity (this, of course, varying with the size of the tire) of the fluid through the valve into the inner tube; the wheel must then be revolved, when the tire will be found to have been rendered proof against the effects of punctures, and will continue so during the life of the tire. We are not at present able to substantiate the above claims from actual experience, but we are promised a sample of the liquid to enable us to make a trial. We have, however, inspected and punctured a cycle tire, in the inner tube of which the liquid had been injected, and it certainly appeared to fulfil the claims made for it. It has also, we understand, been applied to the 3-in. pneumatic tires fitted to an electrical motor-car with successful results.

THE municipal authorities of Nice have agreed to renew their annual subvention of £200 to the Nice Automobile Club.

THE Stearn's Steam Carriage Company has been incorporated at Syracuse, N.Y., with a capital of £150,000.

The goodwill, plant, and assets of the Falkirk District Motor Co., Limited, are for sale. The assets include thirteen Daimler motor-cars.

WE understand that the Bournemouth Motors, Limited, have received a refusal to an application for licences to ply in Southampton streets. At the same time it is announced that the corporation of Southampton are about to establish a motor-car service of their own.

THE Discount Motor-Car Company has issued the first number of the *Motor Mart*, which is intended as a monthly list of motor-cars for sale. No fewer than eighty-six cars are enumerated in its well-printed columns, and there is an interesting short article on "The advantages and desirability of purchasing a second-hand motor-car." In addition to advertising motor-cars for sale, the Discount Motor-Car Company is prepared to examine and report upon motor-vehicles.

FOUR motor-propelled ambulances are now being built for private hospitals in New York. The Roosevelt, Presbyterian, and New York hospitals are to adopt the horseless vehicle, seeing the success St. Vincent's Hospital has had with the electric car it has used for some months. Some time ago two friends of the Roosevelt Hospital offered to give to the hospital two motor-ambulances. These ambulances are now completed and will be put in operation as soon as arrangements are made at the hospital stables for charging the batteries.

A NUMBER of prominent business men of Washington, U.S.A., have arranged to hold a show in that city, commencing December 10th. It will be known as the National Automobile and Sportsman's Exhibition. Convention Hall, a large building without a single pillar and having a floor space of 36,000 square feet, has been secured for the show. A track sixteen feet wide and an eighth of a mile in length will also be constructed in the building, where practical demonstrations of the efficiency of the various motor-vehicles exhibited can be made.

LOCOMOTIVES ON HIGHWAYS.

AT the City Summons Court, Herbert Payne, in the employment of the Val de Travers Asphalte Company, was summoned for driving a light locomotive at a pace exceeding four miles an hour without a competent person to efficiently apply the brake.—Police-constable Green, 891, deposed to seeing the defendant driving a motor-wagon in Liverpool Street at a pace of about six miles an hour, with a van attached laden with asphalte in powder. There was no person in the van to apply the brake, and the defendant admitted that it could not be applied from the locomotive.—The driver said the brakeman was riding on the locomotive with him, his presence on the van being unnecessary as the pace did not exceed four miles an hour.—Mr. Morris, solicitor, for the defence, said the whole question was about the "trailer" behind. That was connected with the motor by iron rods, not chains, and therefore must stop with the motor and was practically a part of it. The constable admitted that there was a man to apply the brake to the "trailer," and the defendant swore the pace did not exceed four miles an hour, therefore it was not necessary for him to be on the "trailer."—Mr. Alderman Samuel Green came to the conclusion that the pace exceeded four miles an hour. The penalty was £10, but he would only impose a fine of 20s. and costs, with a caution.

FURIOUS DRIVING CASE.

AT the Pentre Police Court, on Monday, David Jones, driver of a motor-car, was summoned for furious driving and travelling without lights. Inspector Williams stated that he had cautioned the defendant previously. Defendant was fined 5s for being without lights, and £1 for furious driving.

UNFOUNDED CHARGE AGAINST A MOTORIST.

AT the Sleaford Police Court, on Monday, Robert Harry Gale, King's Lynn, was summoned for that he, being the driver of a motor-car, did not give audible and sufficient warning on passing another vehicle at Heckington on the 10th inst. William Savage, Sleaford, said he was driving with his wife to Swineshead from Heckington, when they met defendant driving a motor-car. He gave no warning of his approach, and witness's pony reared and fell, breaking both its knees. His wife, who was in delicate health, fainted, and while he was attending to her defendant drove off without rendering any assistance. Witness, however, admitted to the chairman that he saw defendant coming some distance off, but was riding with his head down because of the rain. The Chairman said there was nothing in the case, which would be dismissed.

WE hear that Mr. J. B. Dunlop, the father of the pneumatic tire, has been supplied with a De Dion voiturette by Mr. J. McDonald, of Dublin.

TESTS with some new motor-cars by the post office authorities in Montreal, Canada, are said to show a reduction of one-third of the time required in collecting the mail by the horse wagon system. The test was a severe one, as it was applied both on the mountain side and on muddy streets.

AT Messrs. Friswell's dépôt on Holborn Viaduct, E.C., the other day we were shown one of the latest type of De Dion voiturettes fitted with reversing gear. The car is a four-seated one, with reversible front seats, and a novelty is to be found in a detachable luggage carrier fixed to the rear of the car.

THE automobilists of Philadelphia held a parade recently in celebration of the opening of Fairmount Park to the motor-car. Since October 15th, however, every automobile entering the park must bear, in a conspicuous place, a number supplied by the Park Commissioners.

MESSRS. J. BLAKE AND CO., van builders, 148, Mount Pleasant, Liverpool, are now catering for the wants of motorists. They keep a stock of Pratt's motor-car spirit and Carless Capel's petrol, which can be obtained any day of the week, including Sundays.

THE National Automobile and Electric Co., Indianapolis, Ind., have just introduced what they term a New York trap, designed for use in large cities. It is an electric vehicle, said to have a radius of action of about 50 miles on a single charge of the battery. The car is equipped with one 2½ h.p. motor, geared directly to the rear hubs, and has a compensating gear in the motor shaft. The frame is tubular; the wheels are wood, with solid rubber tires, and the vehicle is fitted with ball bearings throughout. It has five speeds forward and three backward, the maximum forward speed being 15 miles per hour.

THE Motor-Car Journal.

LONDON, SATURDAY, NOVEMBER 3, 1900.

[No. 87.]

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

A PLEASANT gathering, to which full reference is made elsewhere, has proved the last of the many meetings in connection with the 1,000-mile Trial. That event appropriately closes the century; what will be the motorists' way of celebrating the advent of the twentieth era is the subject of consideration at a meeting at the Automobile Club to-day (Friday). Geniality was in the air at Wednesday's dinner. Mr. Wallace carried the proceedings through from start to finish in an excellent way, and although they were somewhat protracted interest never flagged. Of those present nearly everyone shared in the honours, and after the distribution of diplomas came a presentation to which all participants in the Trial had contribution. It was the handing of an address with an accompanying purse to Mr. Claude Johnson, to whose initiative and administrative capacity so much of the club's prestige and influence is due. He has worked well for the club, and his labours in the promotion of the recent Trial were the great factor in an event which indicates "an era in locomotion," to quote from the address which was presented him.

Appreciation of Efforts.

In reply, Mr. Johnson was characteristically modest, giving unto others credit for what they had done, and regarding his work in connection with the Trial as a part of his duty to the Club of which he is secretary. We were glad to see the urbanity and the keen interest of Mr. R. J. Burrows, the Club steward, recognised with a spontaneity and enthusiasm which effectually took his speech away. Verily, as Mr. Wallace declared, it is more blessed to give than to receive, judging by the helplessness in which victims of appreciative generosity thus find themselves. Anyhow, the gathering passed off brightly, and should form a capital preliminary to the Club's annual dinner on the 14th—an event which will open a busy season of automobile activity.

The Duke of York on a Motor-car.

AMONG the many cheery asides with which Mr. Wallace lightened the long process of prize giving and diploma distributing was an announcement that the Hon. C. S. Rolls had, on the day previously, taken the Duke of York for a drive on his motor-car. Mr. Rolls was returning to the Hendre, Monmouth, early on Thursday, and will probably again have the privilege of driving His Royal Highness, thus proving the concern of Royalty in our movement. Already the keen interest of the Prince of Wales in automobilism has led him into the ranks of owners, the Duke of Connaught is not unfamiliar with motor-cars, and we look forward to the day when motor-vehicles will be familiar features at all the Royal residences.

Forty-two Miles in the Hour.

MR. C. JARROTT, to whose work in popularising motor-vehicles Mr. Wallace made felicitous reference at Wednesday's dinner, did something more than dine with the Automobile Club on that day. In the afternoon he had succeeded in beating all previous motor-tricycle records in this country, cover-

ing 42 miles 235 yards in the hour, on the Canning Town track, and this, despite the fact that there was rather a bad wind blowing at the time. His times were as follows: 5 miles, 7 mins. 1½ sec.; 10 miles, 14 mins. 7½ secs.; 15 miles, 21 mins. 6½ secs.; 20 miles, 28 mins. 12½ secs.; 25 miles, 35 mins. 19½ secs.; 30 miles, 42 mins. 31½ secs.; 35 miles, 49 mins. 43½ secs.; 40 miles, 56 mins. 52½ secs. We congratulate Mr. Jarrot on his success, and feel sure that every automobilist will join in hearty appreciation of the record thus made. The motor-tricycle was an 8-h.p. De Dion, which carried him through splendidly, for not only did he complete the 42 miles in the hour, but he was able to beat all records *en route*. The times were taken by Mr. F. T. Bidlake.

To Southsea.

As already announced, the run to Southsea only needs better weather than that we have not enjoyed this week to add another success to the records of the Automobile Club. Elsewhere we give a list of the vehicles already entered. Rumours of some other cars, including one or two electric vehicles, are also about, and these novelties will add to the general interest in the event. The Automobile Club will endeavour to meet the wishes of the constabulary along the road, and we would urge all participants to be as careful as possible in this respect. Non-stop diplomas will be given in respect of vehicles which complete the journey from London to Godalming and from Godalming to Portsmouth without a stop and at a speed *not greater than* twelve miles an hour. "Not greater than" is a phrase which sounds rather different to "fully up to the legal limit." Anyhow, it is likely to be strictly enforced.

Passing when Going Down hill.

WE trust that on the occasion of this anniversary run to Southsea there will be no attempts made by drivers of cars to pass other motor-vehicles when going down hill. Such proceedings are frequently risky and might give wrong impressions to observers who are not familiar with the degree of control that can be obtained over an automobile. It is far safer and much wiser to adhere to the regulations of the Automobile Club in every respect.

Liverpool Self-Propelled Traffic Association.

A MEETING of the Council of the Liverpool Self-Propelled Traffic Association has been held at African House, Water Street, Liverpool, with Mr. Alfred L. Jones, J.P., in the chair. The attendance included Lord Derby (President), Messrs. John A. Brodie (City Engineer), Anthony G. Lyster (Dock Engineer), and Prof. Hele-Shaw, F.R.S. (Vice-Presidents), S. B. Cottrell (General Manager and Engineer Liverpool Overhead Railway), Arthur Musker, Henry H. West, Laurence Jones (Hon. Solicitor), J. Walwyn White (Hon. Treasurer), and E. Shrapnell Smith (Hon. Secretary). The programme was arranged for the visit to Liverpool of M. G. Forestier, Inspector General of Roads and Bridges in France, who is to give an address upon "Heavy Motor Traffic in France," at the Liverpool Royal Institution on the evening on Monday, December 3rd. M. Forestier is also to be entertained at a complimentary luncheon on December 4th, by Mr. A. L. Jones, Chairman of the Association. It was decided to

invite the Automobile Club to have a tour to Liverpool in June next, in order to let the people of the city see the many types of light pleasure carriages, whilst the visitors would be able to follow the heavy motor trials which are to be held from June 3rd to 7th, 1901. Mr. Shrapnell Smith having reported to the association that propositions for the formation of road carrying companies were under consideration in Liverpool and Manchester, it was resolved to announce that the association wished it to be understood clearly and placed on record that, having been formed for the purpose of scientific investigation only, it has no connection whatever with any such undertaking.

The Reading Automobile Club.

THE annual dinner of the Reading Automobile Club took place at the Queen's Hotel, Reading, on Saturday last, the 27th ult. Several distinguished automobilists were invited as guests, including Mr. Mark Mayhew, L.C.C., and the Hon. C. S. Rolls, but, unfortunately, the last named was unable to be present, as also was the Mayor-elect. Mr. Mark Mayhew, however, arrived upon his new 16-h.p. Napier car, and received a warm welcome at the hands of the members. In the course of an excellent speech delivered with characteristic tact and gracefulness, he complimented the Reading Automobile Club upon its rapid growth and vigour, and touched upon the usefulness of the motor-car both for civil and military purposes. After dinner the members accompanied him to the covered yard adjoining the hotel, and inspected, with keen interest, his new car. In giving Mr. Mayhew a hearty send-off, the club was mindful of his promise to be its guest upon future occasions to which all the members will look forward. The dinner was well attended, and was in every way a complete success; and, with its increasing and influential membership, the Reading Automobile Club confidently anticipates prosperity in the new year.

Motor-Cars in Cape Town.

WE have been favoured with a sight of a letter just received by Mr. C. Johnson from his brother in Cape Town, in which he says that motoring is very fashionable, and that there are several cars about the town. There was recently an automobile race at some sports held at Newlands, a suburb of Cape Town. Among the spectators was the Governor, Sir Alfred Milner, who subsequently went twice round the ground in the winning car—a De Dion—while the band played "God Save the Queen" and "Rule Britannia," and "the whole crowd cheered their heads off." On a later day there was a big race with eight contestants, including three steam cars entered by the Locomobile Company.

A New Car from Lowestoft.

WE learn that Messrs. J. W. Brooke and Co., of Lowestoft, are at work on the construction of a new car which is to comprise several novel features. The motor, which is being constructed in accordance with the designs and patents of Mr. E. Estcourt, will be of 8½ to 9 h.p., and will be placed at the front end of the frame. It will, it is claimed, only use the same amount of petrol as an ordinary 6-h.p. engine; it has three cylinders, the two outside ones taking an impulse every other revolution, and the middle one every revolution. The motor, instead of being fixed longitudinally with the car, will be located transversely; it will be fitted with the Estcourt-Joy governor and the Estcourt induction valve, and will have two fly-wheels, thus reducing vibration to a minimum. One feature of the motor is that the cylinders will not be cooled to 180 deg. F., but they will be left at considerably over 212 deg. F., a heavy lubricating oil being used. Coming now to the transmission mechanism, the power of the engine is transmitted to the gear box by a chain, and the variable speed arrangements, instead of consisting of gearing as usual, will also be by means of chains, this latter arrangement having been devised by Mr. Mawdsley Brooke. There will be four speeds ahead and one reverse, and the whole of these five changes will be controlled by one lever at the right of the driver. The

car, which in itself will be very similar in construction to the ordinary 6 h.p. Daimler, is said to be exceedingly simple. It is expected to be completed shortly after Christmas.

A Strange Incident.

OUR attention has been called to an incident which we believe is rare among motorists—in fact, we have never before heard of such a case, and hope such an unpleasant affair will not occur again. About two months ago, a couple of tourists hailing from north of the Tweed had run short of petrol at Kirkby Stephen. They called at the house of Dr. Benjamin Walker, who is a motorist. The doctor was out, but his wife kindly allowed them to help themselves from his store. They took three gallons of petrol, and asked for the bill to be sent on—Mrs. Walker not knowing the cost. An invoice for three gallons of petrol has since been sent to these touring motorists, but no reply has yet been received. This sort of thing is very regrettable, and is likely to have a deterrent effect on the *esprit de corps* which has hitherto been characteristic of motorists.

Military Motor-Cars in America.

SIMULTANEOUSLY with the attention the motor-car is receiving at the hands of Continental military authorities comes a significant recognition of the value of the automobile in the annual report which General Miles, commanding the United States Army, has just presented to the American Secretary for War. It has been alleged that, owing to the poor character of the roads in America, the motor-car has no chance; but General Miles is certainly not of that opinion. He reports that, though the three electric cars in use at Fort Myer, Virginia, have not proved wholly satisfactory, this fact has been due to the difficulty of recharging. Hence he and other officers have been making experiments with other types of car, as a result of which he expresses the opinion that automobiles may be adopted for the use of couriers carrying despatches, for the movements of staff officers from one command to another, for small reconnoitring parties, for investigating the topography of the country in which the army proposes to operate, for small detachments engaged in constructing bridges from establishment depôts, for rapidly supplying ammunition, and for the movement and succour of the wounded. For the present General Miles is of opinion that the use of motor-cars will be best adapted to the headquarters of the army and to the departments and outposts of considerable size. He believes that the motor-car is destined to prove a valuable acquisition to the army.

The Motor Manufacturing Co.'s New Voiturette.

ON Wednesday afternoon we had an inspection of the Motor Manufacturing Co.'s new voiturette, which had been driven up by road from Coventry that morning. As we hope to publish a full description, with illustrations, of the car in an early issue, we will only mention at the present time that with its four-seated *tonneau* body and generally low build it has a very attractive appearance. The engine is a 5 h.p. M.M.C. De Dion of the water-cooled type; it is located in the fore part of a tubular frame; three speeds forward and reverse are available, the maximum being twenty-eight miles per hour. Wheel steering is fitted, while the transmission gear is on the lines of that adopted in the Panhard cars. In fact, the new voiturette is practically a miniature Panhard.

The Means of Transports Fete.

THE majority of the owners of the ancient mail coaches, tilburies, berlins, diligences, and sedan chairs now being shown in the Paris Exhibition having declined to permit the participation of their vehicles in the *défilé* through the Champ de Mars and Trocadero grounds, the proposed *fete* of the means of transport has had to be abandoned, much to the disappointment of the crowds now flocking daily to the big show. It

would have been indeed a remarkable procession, but in view of the uncertainty of the weather now prevalent in Paris the owners cannot be blamed for objecting to the use of their valuable vehicles. One has only to visit the section of the Exhibition devoted to these ancient carriages to ascertain what a great amount of interest is taken in these various means of transport by the general public, and what a success their proposed promenade would have scored. Among the early specimens of self-propelled machines none excites more notice than the famous George Stephenson locomotive, exhibited by Sir David Salomons, and around which one always finds an interested crowd. To Englishmen one of the most curious of these first types of the carriage builder's art is the *coucou*, or passenger van, at one time employed for the conveyance of the public between Paris and the environs. The times have indeed changed since then, and speedy motor-cars now do their twenty miles an hour over routes where formerly these old lumbering machines found difficulty in doing five.

The Motor-Omnibus Service for Newport.

WE mentioned last week that Mr. C. D. Phillips has in contemplation a motor-omnibus service for portions of Newport not supplied by the Tramway Company, and, in furtherance of this idea, he has for the past fortnight been engaged in inspecting and experimenting with motor-cars in various parts of the country. The final experiment took place on Monday, when Mr. Phillips started from Southampton for Newport on a fourteen-seated steam car he purchased last week in the Isle of Wight. Mr. Phillips does not intend to place the car in the public service until he has given it a good test. The first of these trials will be as severe as it is possible in the district, for twelve passengers are to load the car and are to be conveyed from the bottom to the top of Stow Hill and back again on a time test. A few particulars of Mr. Phillips's journey from Southampton will be interesting. He left Southampton at ten o'clock on Monday morning, his first stage being Salisbury, 22 miles, which he covered in one hour 45 minutes. At the cathedral city the car was replenished with oil and water, and then a start was made for Warminster, the distance, 21 miles, being covered in one hour 55 minutes. Mr. Phillips left this old-fashioned town at three o'clock, arriving at Bath at 4.25, the distance being seventeen miles. It was the intention of Mr. Phillips to run through to Newport, via Gloucester, but owing to the boisterous weather and the heavy condition of the roads, and it being imperative that he should attend a meeting of the Bath and West of England Agricultural Society on Tuesday, the car was despatched from Bath to Newport by rail.

Accidents caused by Horse-drawn Wagons.

THE lamentable accident to Mr. Rucker's party caused by an uneven road and a timber wagon in Hampshire has not been forgotten by motorists. Nor are they likely soon to lose sight of such dangers, for hardly a week passes without news of some accident or very narrow escape caused by the lumbering and cumbrous vehicles in the country districts. The other day Dr. and Mrs. Grabham, of Blue Mills, Witham, met with a nasty accident at Great Totham, when riding in their motor-car. Dr. Grabham had tried to avoid meeting two wagons and a tumbril at an awkward turning in the road, and turned sharply towards the Board School. In doing this one of the front wheels got too far under the body of the car, which at once toppled over, throwing the Doctor and Mrs. Grabham out. The latter was not seriously hurt, but she received a severe shaking; and Dr. Grabham was badly cut about the face.

A Spill in Essex.

THIS is not the only mishap that has taken place in Essex, for last week an unpleasant incident occurred to a party of motorists about four miles from Colchester. Again, in this instance, there was nothing wrong with the motor; the trouble arose from the puncturing of a tire. It appears that

Captain Kemp and Mr. E. Cook, of Billericay, with Mr. R. C. P. Knights, of Springfield, went to Yarmouth on a motor-car, and after spending a couple of days there set out for home. As they were nearing Colchester the tire of the right hind-wheel became punctured. This caused the car to swerve and overturn. Captain Kemp, the owner, who was driving at the time, had his face badly cut, and lost a quantity of blood; Mr. Knights, who was sitting on the footboard, was likewise injured in the face; but Mr. Cook escaped with only a slight wound on the head. Mr. Knights and his companions soon got the car into working order again and rode on to Colchester, where two of the party remained the night. The next morning Mr. Knights and Mr. Cook rode to Springfield in the car, which has been repaired. Surely the public must see that neither of the accidents we have referred to should be used to discredit the automobile industry.

THE HON. C. S. ROLLS TAKES LORD AND LADY LANGATTOCK AND LORD BRASSEY FOR A SPIN.
Photo by [J. H. Preston Monmouth.]

Note this when in Norfolk.

FOR the third consecutive week, Norfolk and its lordly opponents of the automobile figure in our columns. First it was the Earl of Kimberley, then Lord Cranworth had to be mentioned, and now Lord Walsingham has been suggesting at the adjourned Quarter Sessions held at Lynn that the measures now being taken by the Chief Constable appeared to be all that could be done to stop "the nuisance." At the same meeting, the Chief Constable, Mr. Paynton Pigott, gave further details of the police activity to which we briefly referred last week. He said that since his attention was more particularly called to the matter by the Standing Joint Committee, he had given special instructions to all superintendents and inspectors, giving them liberty, if they thought it necessary, to place all men in their divisions in plain clothes to watch those roads frequented by the cars. All constables who were cyclists were to be supplied with bicycles, and if extra men were required in any division he undertook that they should be supplied—which, of course, is very good of him.

Lincoln Limiting Speed.

THE Lincolnshire County Council has given its approval to a suggestion to add to the Highway Order of 1896 the following: "And when the light locomotive is within one hundred yards distance of a curve so acute that the driver cannot see round such curve, or the junction of two or more roads, or a horse on the highway, the speed shall not exceed six miles an hour; or in the case of a light locomotive, the weight of which exceeds two tons, four miles an hour." The Council have also approved a suggestion that Article IV. (7) should read: "He shall, when about to overtake, and being within one hundred

yards of any cart or carriage, or any horse, mule or other beast of burden, or any foot passenger being on or proceeding along the carriage-way, by sounding the bell or other instrument, required by Section 3 of the Act, give audible, continuous, and sufficient warning of the approach or position of the light locomotive."

Sensible Northampton.

NORTHAMPTONSHIRE has a goodly number of sensible people on its county council. A certain section of the members of the council wanted to reduce the speed of motor-cars from twelve to ten miles an hour, but at the meeting last week the motion was defeated. Colonel Stopford Sackville thought there was no danger in cars travelling even fifteen miles an hour. The Marquis of Northampton said motor-cars generally went about eighteen or twenty miles an hour. If the speed were limited to twelve miles that would, he thought, be sufficient. If he had to choose between two dreadful alternatives he would just as soon be pitched out of a motor-car running at full speed as out of a carriage drawn by a pair of horses.

Middlesex Moving.

THE Middlesex County Council have adopted a recommendation of the Highways Committee, that bye-laws be made putting the maximum speed of motor vehicles at ten miles an hour, instead of twelve as at present, and laying down that when approaching a curve, or the junction of two roads or a horse, the speed be reduced to six miles an hour, and that all locomotives should be registered and numbered. The chairman of the Council said it was the intention of the Local Government Board to fix a maximum rate of speed—a fact which he evidently thought was a bit of news worth retailing.

A Word to Mr. Spear, M.P.

WILL the motorist M.P.'s kindly take one of their new colleagues, Mr. J. Spear, M.P., in hand, or rather take him for a ride on a motor-vehicle? At a conference of parish and district councillors in the Holsworthy district of Devonshire he has been declaring in favour of the taxation of motor-cars. At the same time a resolution was adopted in favour of the taxation of cycles and motor-cars. Really some kind legislator should explain matters to Mr. Spear.

Attempts at Record-Breaking in America.

MR. WILLIAM K. VANDERBILT, the well-known American *chauffeur*, recently attempted to make a record run from Newport to New York, but the attempt was not successful owing to a lack of preparation, no knowledge of route, too much bad roads, and worse weather. Leaving Newport on Saturday, the 29th September, at 7.15 a.m., the journey ended in New York a few minutes after 11 o'clock on Sunday night the 30th ult. The big German-Daimler racer carried three passengers—Mr. Vanderbilt at the wheel, an expert mechanic on the seat beside him, while the rear seat offered a not too comfortable lodging place for a coachman, who earned his keep by manipulating an ear-splitting syren of gigantic proportions. During the evening and early morning hours the road ahead of the big car was brightly illuminated by an electric headlight of searchlight power. Mr. Vanderbilt's own ideas of the journey were these: "It was a very hard trip, because the rain had made the roads very muddy and soft. Early in the journey I saw the futility of trying to make a record and concentrated all my energies on bringing the machine through in good order. But despite all I could do we experienced more than our share of hard luck and seemingly unexplainable breakdowns and delays. I nursed the big fellow all through the ride to prevent any serious breakdown occurring, and I congratulate myself that I succeeded in doing so when almost any other machine would have gone down under the roads we were driving over at almost top speed. Finally the rain became so bad that we had to seek shelter and wait until the worst of it was over. This of itself settled any idea of

record work, and while I am of course disappointed, I am sure with the experience I have had on this trip and with only a fair share of good luck and weather I can and will put up a set of figures for a journey between New York and Newport which will be worthy of vehicle and of its driver as well."

In Madagascar.

WE HAVE previously referred in these columns to the use made by General Galliéni of automobiles in the island of Madagascar, and it is now reported that the general's trials of a car between Mahatsara and Tananarive have proved so successful that he has decided to largely extend their sphere of action. Both the valley of the Mangoro and the Majunga route will have automobile services, and it is rumoured that the lorries sent out some time ago to the Soudan will be shortly transferred to Madagascar, where they will be able to work under more advantageous conditions than those prevalent in Northern Africa. The French colonies are practically enthusiastic on automobile matters, and hardly a week passes without a new service being opened up in one or other of them. Given some sort of roads, the cars acquit themselves creditably, but are not in their element, when, as in the case of the Soudan, routes are conspicuous by their absence. In a few months Madagascar should be well to the front in the matter of automobile services.

Motor-Car Exhibition and Races at Leipzig.

IT was on Friday, the 19th ult., that the much talked of automobile exhibition at Leipzig opened its doors, and since that date it has been daily patronised by a very fair number of visitors. The inauguration was witnessed by a considerable gathering, and if several of the exhibitors' installations were not entirely finished, the show was no worse in this respect than are the majority of exhibitions. To celebrate the opening of Leipzig's first automobile show right worthily, a series of races had been organised for the 19th ult., and these were duly held, to the great delight of the local sportsmen, many of whom had never seen an automobile *course*. In spite of the terrible conditions of the roads not an accident has to be recorded; indeed, from every point of view the meet proved an unqualified success. Leipzig can boast of a sport-loving populace, and they turned out almost to a man to look at the motorists fly by, for not every day are they afforded an opportunity of seeing a motor race. Needless to say the local *chauffeurs* also mustered strongly, and many of them actually participated in one or other of the categories. The three classes of the principal event each received an excellent complement of entries, and even the special race reserved for the heavy transport cars did not lack competitors. The official returns were as follows:—Cars: 1, Schaller, of Berlin, in 3h. 9m. 46s.; 2, Popp; 3, Isbert. Voiturettes: 1, Kirchheim, of Eisenach, in 2h. 47m. 30s.; 2, Meyer; 3, Mathis. Motor-cycles: 1, Cudell, in 2h. 59m. 27s.; 2, Munkwitz (motor-bicyclist). Heavy cars: 1, De Dietrich, in 58m. 15s.; 2, Marienfelde Works; 3, Eisenach Works. The heavy vehicles were only called upon to run over the Wurzen-Leipzig route, hence the difference in times. Cudell was riding a De Dion machine and Kirchheim a Decauville. The latter took the special prize of three hundred marks presented by the town of Leipzig.

THE design of a 40-seated steam omnibus has been registered by Mr. Henry Mozley, general manager of the Burnley and District Tramways.

AMONG new recruits to the motor world is Mr. Webster, of Chislehurst, who has purchased a 6 h.p. Marshall dogcart. Mr. W. Jackson, of Bradford, has also become a devotee of the Marshall car, with which he has expressed himself completely satisfied. In fact he regards it as better in workmanship than any car he has previously owned.

THE Accumulator Industries, Ltd., of Silver Street, Bloomsbury, W.C., are introducing the "Cupron-Element" a constant current primary battery which is recommended for the charging of ignition accumulators. The element is being made in four types, viz., 50, 100, 200, and 400 ampère-hours.

A CRUISE ON LAND—OR THE LOG OF A MOTOR-CAR.

BY MISS DOROTHY EDMUNDS.

WHEN my father returned from the 1,000-mile Trial he said he would like to take my mother, brother, and myself on a similar journey, employing two cars, one to carry the passengers and the other the luggage, so as to make us perfectly independent of trains and their time-tables and connections, and to feel the freedom of being able to go as you please and stop when you like. We decided to start on August 3rd, at which date a new Parisian Daimler—6 h.p., fitted with all the most recent devices, such as Mossberg roller bearings, Escourt cooler, electric ignition, Falconnet of Paris compound tires, etc.—was timed to arrive. Owing, however, to some delay, the car could not be completed before the Bank Holiday,

Aylesbury. After tea, we replenished our petrol locally (at 1s. 3d. per gallon), and set off for Banbury, *via* Bicester and Aynho; but about twenty-five minutes after leaving, the storm which had been so long looming burst upon us in all its fury, and in a few minutes (in spite of mackintoshes and waterproofs) the rain came down in such torrents that some of the party were practically drenched, and here the difficulty of not having our luggage with us was severely felt. However, we determined to push on, and, in face of the terrific gale of wind and rain, the engine behaved admirably, the burners keeping alight, and the car making her average twelve miles an hour. Unfortunately, as the storm increased, the roads became so severely washed in places as to be in a dangerously slippery condition, and we had to proceed cautiously. Owing to the storm, we hardly encountered anything on the road. At one time, however, we met a drove of some twenty or more horses, the animals being entirely free from halters or bridles. It was interesting to note that though the car continued on its way, none of the horses evinced the slightest fear. It was fortunate this was so, for had there been a stampede no one knows what might have happened in an open country and a wild night such as we were experiencing. Later on we had to overtake and pass a long caravan (evidently proceed-

IN FRONT OF THE GROSVENOR HOTEL, CHESTER.

so we decided to leave London in the old car, the 6-h.p. Daimler (which was numbered A 12 on the 1,000-mile run) and to take up the new car *en route* at Leamington. Friends in Oxfordshire, Keswick, Ayrshire, and Yorkshire, knowing of our projected trip, had kindly invited us to stay with them while in their respective districts. It will probably be remembered that the latter end of July was warm and fine, and we hoped to have the same weather in August; but, unfortunately, on the morning of Friday, the 3rd, we saw that the glass had fallen precipitately, and ominous-looking clouds indicated we might expect a sudden change in the weather. After some deliberation we decided to make the start, and left Streatham at noon *en route* for Banbury, Oxfordshire, a distance of about seventy-eight miles, where we were due for dinner at 7 p.m.

Not having the second car, we sent the luggage in care of the man by train. We ran through Putney, thence to Uxbridge and Amersham, then to Aylesbury, where we arrived about four o'clock, and had tea at a very comfortable old-fashioned hotel there. The roads we had traversed were fairly good, though many of them were wet through recent showers; but we did not experience any rain to speak of before reaching

ing from and to some country fair) consisting of quite a number of vehicles and horses of all sorts and conditions. The drivers on their waggons could not see us, sheltering themselves from the storm, and as we were coming from the back it was with the greatest difficulty we could make them hear and give way for us to pass. The road at this point being none too wide, and not of the best, made this a somewhat difficult and delicate operation. However, we pushed on, the storm, if anything, increasing, evidences of its fury being indicated by miles of road strewn with leaves, branches, and in several cases large trees blown dangerously near our path. At 7.15 we made Banbury, our friends having given us up, never dreaming we should dare such a journey on such a night. Thanks, however, to our clothes having preceded us, and to certain mysterious draughts which the elder of the quartette drew from time to time from a large flask, none of our party seemed any the worse next morning for their thorough drenching. We remained in Banbury for several days, the weather for the most part being simply awful; but, notwithstanding that, the car took runs almost daily, conveying many friends to several points of local interest. On the 10th we left Banbury for Leamington, a run of

twenty-one miles, which we made in about two hours. We stayed at the Regent Hotel till our new car arrived, and left on the following Tuesday, having visited many of the charming spots in this lovely district. On the Tuesday we left for Shrewsbury, *via* Stratford-on-Avon and Wellington, and from here the run of the two cars began, the old Daimler (driven by the man-servant) carrying the luggage. The cars were weighed, the old one, with luggage and driver, complete, about 26 cwt., empty 22 cwt.; the new one with passengers (when weighed it had five on board) turned the scale at 31½ cwt., empty 24 cwt. An interesting point, however, was that both cars were built by the Daimler Company, the dimensions of the engines being practically the same; therefore we were looking forward with great interest to their relative performances. The new one was of the "Iveagh" phaeton design, carrying a hood and good leather aprons (to protect us from the weather), which on several occasions we found most useful, and which saved us from ever being drenched again. The run to Stratford was uneventful. The road is good, practically level; the distance about ten miles, which we ran in under fifty minutes. This being the first journey of the new car, we ran cautiously and not much on top speed, and, notwithstanding, arrived ahead of the old car by about ten minutes. She was running entirely on electric ignition and not using the burners at all. After lunching, and visiting several places of interest

THE NEW CAR ON ITS RETURN HOME AFTER THE RUN.

connected with the immortal bard, and taking several photographs, we continued on our journey, making very good running through Alcester, Bromsgrove, Kidderminster, and Bridgnorth. The very good roads through this part of the country are surrounded by picturesque and beautiful scenery. We stopped at Bridgnorth to inquire as to the way we should go to Shrewsbury, and were advised to go *via* Wellington. We soon, however, began to encounter very hilly and rough roads, in many cases very narrow, sharp inclines, which tested, for the first time, the hill-climbing capabilities of the new car. Seeing she was a new one, she negotiated these fairly well. After running through somewhat uninteresting mining country, with its ironworks and slag-heaps, we got on to the old Roman road for Shrewsbury, and on the last ten miles into Shrewsbury we were able to make up the average to twelve miles an hour. I do not know what speed we were running, but we seemed to overtake a good many cyclists, some of whom rode remarkably well. On this run the new car kept well ahead of the old one, being some 20 per cent. faster. The cars evidently caused considerable interest to the good people in Shrewsbury as we stopped to inquire the way to the old-time hostelry known as the "Raven."

Next morning we viewed several places of interest, amongst others the Quarry Walk, during which time the cars were being

cleaned and overhauled; and here it was noticed that several bolts were missing from the flanges of the French Falconnet tires. These had to be made good by a local cycle-smith, but at 12.52 we were enabled to take our departure for Liverpool. The roads were undulating, but the scenery most varied, on to Wem, where we stopped and had lunch, the cars evidently causing much interest among the people of this quaint village. We afterwards left for Chester, *via* Whitechurch, a run of some thirty miles. Soon the roads improved, the surface being magnificent, but as I could not see the mile-posts, and we had no cyclists to compare by, I am not sure at what rate we were travelling, but we were not at all disappointed with the performance of the car. We arrived in Chester at 4.15, and had tea at the Grosvenor, waiting for the second car, which had left Shrewsbury at the same time we did. After staying an hour and three-quarters we thought it better to push on in order to get to Liverpool in time for dinner. We made for Birkenhead, as we had to cross the ferry at Woodside, where we arrived a little after six. At the ferry we had to wait a very long time; the surroundings leading to the boat were not pleasing, and the behaviour of the horses, the drivers of which were unaccustomed to motor-cars, was very trying to the nerves of some of us. However, through the kindly offices of a man waiting to cross the ferry, the car was enabled to get an exceptionally good position on the boat, so that it was the first vehicle to leave on reaching the other side of the Mersey, greatly to our own relief and to some of our fellow-passengers. Our new friend volunteered to act as pilot to take us the most direct route to the Adelphi Hotel, where we arrived among a gaping crowd at 7.30.

Meanwhile nothing had been seen of the second car with the luggage, and as this was a somewhat necessary accompaniment to our night's enjoyment at the hotel our pilot was sent down to the ferry to make inquiries. However, it arrived at about 8.30. Though the Adelphi was a very comfortable hotel, we were very pleased to leave at 11.30 in the morning. I overheard father say something about the charge for storing motor-cars in the livery stables of the hotel being outrageously high. We were now making for Windermere *via* Ormskirk, Preston, Lancaster, Carnforth, and Kendal. Since this journey from Liverpool to Ormskirk I have wondered if there are any people in Liverpool who have motor-cars who ever made that journey twice and survived it. Fortunately the tires of the car were new and thick and we didn't go at any speed at all; the feeling was something like tobogganing in a bath chair down a flight of stone steps, and suddenly a few miles from Ormskirk the machine ceased to go altogether. I overheard some remarks about valves, electric ignition, and burners, and apparently a sort of game of hide and seek was going on which occupied over an hour, during which all sorts of spanners and tools seemed to be used in all parts of the engine, but still it refused to go; meanwhile the other car had come up, and a consultation was being held as to what should be done. Owing to the condition of the roads it could only just drag itself along, and therefore could not think of taking us in tow. However, I heard something about the spindle on the cam-shaft being jerked out of place; a single touch and it was immediately right, and directly afterwards we were again on the way. Shortly after this we reached Ormskirk; then the roads improved, and we rapidly began to make up for our serious loss of time. As we neared Preston we overtook two friends on bicycles who, knowing of our journey, had come out to meet us, but had given up expecting us in consequence of the delay. We, however, took them on board and put their bicycles on the luggage car, and arrived at Preston Park Hotel at 1.30, where we found a capital lunch awaiting us.

(To be continued.)

UNDER the name "Perfection" Messrs. Warburton, Allen and Co., of Rutland Street, Leicester, have introduced a special air cushion for the seats and back rails of motor-cars. The cushions, which are claimed to entirely absorb vibration, can be made in any size or shape and can be covered in any desired material; the firm, however, recommend Pantasote for motor-cars, this material being unaffected by grease or wet.

THE ANNIVERSARY RUN TO SOUTH-SEA.

THE following is a list of entries for the Automobile Run to Southsea on Saturday next, the 10th inst., so far as they have been received at the Automobile Club up to Wednesday night, the 31st ult. Automobilists are reminded that the run is open to all motor-car owners, whether they be members of the club or not.

VEHICLES ENTERED FOR THE RUN.

Official Number.	Name of Owner.	Name of Makers, &c.	Horse power of motor.	Motive Power.	Number of seats, including driver.

THE COLUMBIA VOITURETTE.

HEREWITH we illustrate a neat little two-seated petroleum-spirit motor-car which has lately been put on the market by the Electric Vehicle Company, of Hartford, Conn., U.S.A., and Paris. The vehicle, which is known in America as the Columbia gasoline runabout, is operated by a single-cylinder motor of 4 h.p.; it is of the water-cooled type, and

THE COLUMBIA VOITURETTE.

is fitted with electric ignition. The water tank, which is situated in the front of the vehicle, holds four gallons, and is equipped with a radiating coil. The petrol tank, which has a capacity of five gallons, or sufficient for a run of 100 miles, is situated under the seat. The power of the engine is transmitted direct to the rear axle without the use of belts or chains. Three speeds ahead and one backward, operated by a single lever, are provided, the maximum speed being about twenty miles per hour. Steering is controlled by an inclined hand-wheel, the pillar of which is pivoted at the bottom to allow of easy access to the seats. The road wheels are of wood, all being 28 in. in diameter, and shod with 3 in. pneumatic tires. The car, which, as will be seen, has a neat and attractive appearance, weighs complete about 1,300 lbs.

MOTOR-CARS ON THE CONTINENT.

(From Our Own Correspondent.)

The Accident of the Paris-Roubaix Race.

It is interesting to note that on Friday, the 26th ult., at the Versailles law courts the report of the expert appointed to ascertain the responsibility of the Croix de Noailles accident was read, and the conclusion arrived at was that to the imprudence of the public must be attributed the responsibility of the mishap. And to this imprudence of the public did the Parisian motor world suffer three months of persecution, and French automobilism lose an entire season of racing. Paris-Bordeaux, Paris-Lille, Paris-Brest, Paris-Ostend—all were this year lost by reason of the unfortunate mishap at Saint Germain, an accident which would never have occurred at all had the spectators not been seized with the mad idea to mass themselves in the middle of the route and at a dangerous corner. But there it is, and now I wonder what will be done with MM. Martin and Dorel, the two motor-cyclists who ran into the crowd, and who have been regarded by many as the culprits in the affair. I take it that the court will abide by the expert's report and acquit these two unfortunate racers; but one is never sure in a court, especially where an automobilist is involved. In any case, it is time that the affair was finished, for the accident took place as long ago as April 15th.

The King of Belgium.

To the ranks of royal automobilists King Leopold of Belgium must now be definitely joined, and judging from his enthusiasm when in Paris his adhesion is likely to be a strong and lasting one. Last week I made mention of his call upon the President of the French Council at the precise moment when the latter was descending from a motor-car, and whether or not the sight inspired the monarch I cannot tell, but the fact remains that a visit to Charron's resulted, and a few days later His Majesty was seen speeding through the streets of Paris, driven by the winner of the Gordon-Bennett Cup in a 24-h.p. Panhard. From that day King Leopold has indulged in frequent trips, and, although mounted on a big racer, has so far escaped a police summons. What a chance to be a king! When I think that the Belgian monarch can drive at seventy kilomètres an hour through the Bois without receiving anything worse than bows and scrapes, while I, for the same performance, should receive a shoal of *contraventions*, I sympathise with the Socialists and similar animals. On Sunday last bad weather only prevented His Majesty from journeying to Chantilly *en auto*, and even as it was he made his promenade in the forest mounted on a car. Long live the King!

The South-Eastern Cup.

As was naturally to be expected after the experiences of the first competition for the South-Eastern Provincial Cup, changes in the rules governing the contest are likely to take place, and the Sporting Committee of the Automobile Club of Nice has decided to submit certain modifications to the Federation of the Automobile Clubs of the South-East. It will be remembered that the race of April 4th last was actually won by M. Cuchelet, representing the Salon Club, but upon the protestation of the Nice representatives the cup was eventually handed over to them. The ground of the complaint was that the winner was not a genuine member of the Salon Club, but had been elected simply for the purpose of contesting the race on its behalf. The proposed changes in the rules provide for a residential qualification, and further stipulate that every competitor shall have been a member of the club he represents for at least a year previous to the contest. This appears perfectly just, and will doubtless meet with the approval of all concerned. The race will be decided in the spring over the same route as last year, viz.: Salon, Aix, Orgon, Tarascon, Arles and Salon. A

keen contest is anticipated, and I am not alone in the wish that this time Salon will secure the trophy. They are sportsmen down yonder.

Parisian Tramways.

PARIS has been overwhelmed during the last few months with tramcar accidents, and undoubtedly the self-propelled specimens of this type of public conveyance are driven much too fast. That serious steps are at last about to be taken to reorganise the management of the vehicular circulation in general, and that of the tramways in particular, is evidenced by the action of Monsieur Touney, the director of the municipal police, who has circularised the police directing them to prepare a return showing, firstly, the accidents caused by the tramways during the month of May, and secondly those which have occurred since June 1st last to date. These returns are required to specify distinctly between mishaps where horse-drawn and self-propelled vehicles have been the victims, and all Parisian automobilists unite in the hope that this step is the forerunner of stringent measures about to be taken for the regulation of these huge cars. Paris is rapidly becoming a perfect network of tram lines, upon which half a dozen different electric systems, not to mention compressed air, horse, and steam cars, career at an alarming speed. The rails are dangerous enough for the Parisian motorists, but the cars themselves add tenfold to the danger, and not a day passes that an accident is not recorded.
